minute as to escape detection in post-mortem examinations, so that it was believed by the late Dr. G. H. Barlow that the pus escaped by transudation through the coats of the bronchi without breach of continuity. An interesting point in the case is the fact of the opening into the lung occurring after not only the creation of two artificial openings into the chest wall, but also after a spontaneous pointing (for if the fluctuating tumour had not been lanced, it would speedily have burst, as the wall was already thin and red); and Dr. Wilks has pointed out<sup>3</sup> that the lung gives way more readily than the chest wall. This case resembles one described by Hillier<sup>4</sup> in the fact of the pus making its way into the lung after paracentesis has been performed; but I have not met with any record of such an occurrence after spontaneous opening of the chest wall. Is it not possible that this may have resulted from the actual advance towards recovery, the gradual expansion of the previously compressed lung distending and enlarging what was before but a superficial ulceration of the condensed lung tissue, until it became a gaping wound and allowed a free passage to the pus? The fact that the position of the heart had changed more nearly to the normal before this took place would seem to point to some such explanation of this curious fact. The mode of evacuation through the bronchi has been generally considered to be a favourable mode of termination in these cases, and in the present one no doubt the favourable result is due to this cause, finally, if not altogether. The experience of Dr. Wilks<sup>5</sup> would seem to throw a doubt on this, but here the improvement was marked as soon as the mechanical result of the escape of fluid into the lung had passed. This case shows also how little harm is done by the entrance of air into the pleural sac in cases where the contents are already purulent if free drainage be provided, and the air itself be free from the special septic germs which too often abound in the air of the hospital ward. The pus was perfectly sweet throughout the case, and I do not think that the case could have done better had the Listerian precautions been carried out in all their integrity, a task which is often impracticable in dealing with patients of this class in their own homes and without assistance.

Dr. Fuller, in his work on Diseases of the Chest, has pointed out that it is difficult to believe that air does not enter the pleura even under the most careful precautions during aspiration, for either this must occur or the lung must immediately expand, or, thirdly, the chest walls must fall in, to permit the exit of any effectual quantity of the fluid contents. But we know that even in cases which pursue a favourable course the lung does not at once expand, nor even in children, when the chest walls are most yielding, do they at once collapse. We are therefore driven to a conclusion which is *a priori* probable, that air does enter the pleura by the side of the needle or cannula. The more resilient the chest walls and the compressed lungs the less is the amount of air thus admitted, but it is probable that in all cases it finds entrance in some degree proportionate to the quantity of fluid withdrawn.

There were unmistakable symptoms of pneumonia associated with the pleurisy in the early stages; whether these were coincident, or, if not, which was the prior affection, I am not able to say, further than that there were crepitation and bronchophony when first seen by me, and rusty sputa very shortly after.

It has been well pointed out by Dr. Wilks, in the paper already cited, that whenever local dulness with absence of breath sounds persists after an attack of chest disease, "by whatever name it has been called," a local empyema may be suspected; his words are stronger—"is present"; and that when an acute pneumonia ending in resolution leaves no result behind, it is the pleurisy which accompanied or succeeded the pneumonia that continues to progress, and a local empyema is the result, and this he tells us is "positive knowledge gained by inspection," and certainly this case, so far as it goes, bears out his statement.

<sup>1</sup> "Hardly is there any affection that cannot be considered as having sometimes been produced by a reflex action, the cause of which is an injury, a disease, or at least an irritation of a nerve." (Brown-Séquard on Diseases of Nerves—Holmes' System of Surgery, Vol. 3, 1862.)

<sup>2</sup> THE LANCET, Feb. 26th and March 6th, 1891.

A NEW HOME for Incurables was opened at Mauldeth by the Bishop of Manchester on the 15th inst. Accommodation is provided for 100 patients. The building, which was purchased for £15,000, and to which a wing has been added at a cost of £8000, was originally occupied by the Bishop of Manchester.

## BRAIN WEIGHT AND BRAIN POWER.

BY SURGEON-MAJOR J. P. H. BOILEAU, B.A., M.D.,  
DIPLOMATE IN STATE MEDICINE, UNIV. DUB., ETC.; ASSISTANT PROFESSOR  
OF PATHOLOGY, ARMY MEDICAL SCHOOL, NETLEY.

ALTHOUGH the connexion between the relative weight of man's brain and his intellectual development is very well known, and several illustrations of this connexion have been published, I feel assured that the following notes of a remarkable case may not only well be added to the list of those already recorded, but that it is desirable that this should be done. It is the case of an officer who died at Netley last year, and I am indebted to a published memoir for some particulars of his life.

A Scotchman by birth and parentage, he received his early education in Edinburgh, and afterwards went to Wimbledon School previous to entering Addiscombe, where his career was exceptionally brilliant. At the final examination there, he scored an unusual total of marks, gained the sword of honour and Pollock medal, and several prizes for specific subjects. On leaving Addiscombe in 1858 he proceeded to India, where he was employed altogether in civil duties. At the time of his death he was superintendent of the telegraph department. With no military distinctions, he was nevertheless one of the foremost men in his corps. Highly gifted intellectually, duty no less than inclination prompted him to cultivate his mind as a preparation for advancement, for he held strongly that no one is fit for highly responsible positions who fails to keep himself as far as possible on a level with current events, and with the thoughts, investigations, and discoveries of the day. His wide reading and tenacious memory made him a man of mark in any society. His opinions were his own, formed independently, expressed if necessary forcibly, and followed always courageously. He was an exceptional man, and his large-hearted and wide-reaching sympathy won him admiration and love among high and low. His remarkable qualities were as conspicuous in his earlier as in his later years. He was a standard of conduct to his schoolfellows, and when at Addiscombe the governor did him the extraordinary honour of making a private report to the board of directors of the East India Company, which was quoted by the chairman on the examination day. The reputation with which he started increased daily, and was sustained to the last. But the strain was too great. Exposure to a pernicious climate—and his physical strength led him to expose himself only too carelessly—for twenty-four years, with but eighteen months' leave, weakened a naturally magnificent constitution, and he was compelled to take furlough. His intellectual vigour, however, was shown nearly to the last, and only a few days before death he expressed his capability of undertaking difficult mental work. But a sudden change set in, and in a few days proved fatal.

During his stay at Netley he suffered from extreme debility, induced probably by intractable diarrhoea. A day or two before death he complained of severe headache, and his axillary temperature rose from 101°–102° to 106° F.

It is very much to be regretted that at the time I was called upon to make the autopsy I was not in possession of the facts narrated, for had I been the examination would have been more complete in many points. The diagnosis of the case was very obscure, but hepatic abscess was suspected, and it was to clear up this point that the examination was made. The severe headache, however, and the rise of temperature pointed to some cerebral or meningeal mischief, and it was thought advisable to find out if such existed. For this purpose the cranium was opened.

*Abstract of autopsy* (made not only with the full permission of relatives, but, I believe, by request).—Cranial bones very dense; dura mater extremely vascular; brain substance generally firm and normal. On opening the left ventricle pus was observed in the anterior cornu; the origin of this was in the anterior part of the intraventricular portion of the left corpus striatum, which here was quite destroyed and broken down into soft shreds. Before dissection the brain weighed 26,130 grains avoird., or 59.72 ounces. After examination, a portion of it, weighing 22,785 grains, was found to displace eighty-six cubic inches of water; the specific gravity was therefore 1.049. The lungs were perfectly healthy, with the exception of the lower lobe of the right. In this there was a circumscribed abscess

cavity measuring in its longest diameter three inches. It communicated with a small abscess in the liver through an opening about the size of a florin in the diaphragm. The heart was quite normal. The lining membrane of the great bloodvessels was deeply blood-stained, that of the aorta being very much roughened in patches by atheromatous degeneration. Jejunum, ileum, and colon normal; no trace of ulceration, but the solitary glands of the latter were large and prominent. The liver presented a uniformly brown colour throughout, and was much softened. In the upper portion of the right lobe there was a small abscess about one inch in diameter, and nearly surrounded by a dense thick fibrous envelope. This abscess communicated with the lung. The spleen was slightly enlarged, weighing 4375 grains. The kidneys appeared to be quite normal; they were enveloped in a large amount of fat.

The chief interest in this case lies in the great weight of the brain, and its high specific gravity, in relation to the highly gifted intellectual power exhibited by the individual during life. As this brain weighed very nearly 60 oz., it exceeds that of all others usually quoted, with the exception only of Cuvier's, which weighed 64½ oz., and that of Dr. Abercrombie, which weighed 63 oz.<sup>1</sup> Sir J. Y. Simpson's brain weighed 54 oz., and that of Agassiz 53.4 oz. It is well known that the average weight of the adult male brain is under 50 oz. The specific gravity of the brain I examined was 1.049, and this is as high as any recorded. From Professor Aitken's work I find that the average specific gravity of the brain is 1.036, and the highest specific gravity of the densest part of a brain ever taken by Professor Aitken, or anyone else I believe, is 1.049.

The weight of the brain in this case was in the first instance taken by the orderly corporal in charge of our microscope room, and recorded by him on the black board in the mortuary. I immediately verified its accuracy by weighing the organ myself, and I also verified the correctness of the weighing machine. The specific gravity was taken very carefully. Surgeon-Major Hogg, Army Medical Department, was present at the time.

The average cranial capacity of the adult male head is, I believe, about 90 cubic inches. Cuvier's is reported to have been about 118. In the case which I now record it must have been about 108.

## THE INTRA-VENOUS INJECTION OF FLUID FOR SEVERE HÆMORRHAGE.

BY C. EGERTON JENNINGS, L.R.C.P. LOND.,  
RESIDENT ACCOUCHEUR, AND FORMERLY HOUSE-PHYSICIAN, AT THE  
LONDON HOSPITAL.

(Concluded from p. 437.)

STUDENTS, with smiling faces, are rapidly leaving the theatre of one of our metropolitan hospitals. The most brilliant operator of the day has just performed immediate transfusion with the greatest success. By means of a very beautiful instrument, the most complex and ingenious that modern science has as yet produced, a skilful surgeon has transfused half a pint or perhaps a pint of blood from a healthy individual to a fellow-creature profoundly collapsed from the effects of severe hæmorrhage. Some little difficulty was experienced prior to the operation, as one of the many stopcocks of the transfusion-apparatus was found to work stiffly, but this error was quickly rectified by a mechanic in attendance. Towards the close of the operation the blood-donor, a powerful and heavy young man, swooned. Two porters carried him on a stretcher into an adjoining room, his wounded arm being bandaged up, *secundum artem*, by energetic dressers. Diffusible stimuli were exhibited by the mouth, nostrils, rectum, and skin. The man rallied in due course, being well cared for by a group of students and nurses deputed to look after him. The wound in his arm will probably heal speedily, or a few weeks later he may possibly apply at the out-patient department of the hospital, presenting an ugly-looking pulsatile tumour, associated with a thrill and rasping bruit, connected with the vessels in the

<sup>1</sup> A case is recorded in the Brit. Med. Jour., 26th Oct., 1872, by Dr. Morris, in which a brain examined at University College, London, weighed 67 oz. It was that of a bricklayer who could neither read nor write.

cubital triangle—a most unfortunate accident having clearly happened here, of which a record promptly appears in the columns of THE LANCET.

Time rolls on, and a spectator of the duplex operation, possessed of an instrument such as he had seen employed, finds himself at midnight, in a lone house in the country, face to face with an alarming case of post-partum hæmorrhage. He has adopted the modes of treatment recognised as judicious for the condition before him. He has employed active hæmostatic agents, and finally that potent but highly dangerous styptic, perchloride of iron. His patient is blanched and collapsed to the last degree. Are not her bloodvessels so thoroughly drained of blood that there is not sufficient of that element circulating in the uterine walls to stimulate to permanent contraction its muscle fibres? Is not this the very case for transfusion? The accoucheur puts his apparatus in order (he may not have it with him, and be obliged to send home for it) and selects a blood-donor. He has little time or opportunity under the circumstances I have depicted to find an adolescent, healthy beyond a doubt; little time has he to eliminate the existence of syphilis or of other specific communicable diseases by a well-planned examination of the youth, nor to obtain a knowledge of his previous history and mode of life. The operation is commenced; the blood-donor faints; the friends of the patient, the necessarily improvised assistants to the accoucheur, faint also. The operation is abandoned, and it and he who proposed it fall into disrepute. But there may fortunately have been time to summon a skilled assistant. The veins both of blood-giver and recipient may have been dexterously opened, and transfusion commenced. Still, accidents may even now happen; a small coagulum may form within the apparatus, or a little air gain access through some contingency to the veins operated on.

The picture is carried far enough. Is the operation of immediate transfusion, as taught and elaborately performed in hospital practice, where there is every means of ensuring success, one of universal application? Is it one that can always be performed when most needed—under urgent circumstances and at a moment's notice, often in the night, at Land's End, John O'Groat's house, or Ratcliffe-highway, and by an unaided operator, with everything against him?

If the practitioner have not at his command, when circumstances indicate its employment, a transfusion-apparatus, what can he do? Imitating Treves, he may file down the bone nozzle of an aural syringe, and through this rude but efficient cannula administer an intra-venous injection.<sup>1</sup> No satisfaction can possibly be greater than, under compulsion, to have operated successfully in such a manner. But would it not be far better were some simple method known, which, being of ready application, and not requiring complex, expensive instruments, difficult to manipulate and otherwise objectionable, might be employed by every medical man in the kingdom with ease, expedition, and safety? This question forced itself upon me very strongly when, in the case I have recorded,<sup>2</sup> I administered, with the three-ounce metal transfusion-syringe of the London Hospital (as represented by Fig. 1), an intra-venous injection, the pro-

FIG. 1.

cedure being, in my estimation, fraught with the risk not merely of admitting air whilst detaching the body of the syringe from its nozzle by means of a screw, for the purpose of refilling the instrument, but also with the danger of injuring important structures adjacent to the vein selected for operation (in the case of the median basilic vein, the brachial artery) with the point of the nozzle; for the syringe being many times heavier than the nozzle it was impossible for me to hold the latter steadily during the proceeding. Fig. 2 illustrates an instrument which, to obviate the objections I have mentioned, has been made for me by Maw and Co., and has been briefly described in my paper of last week. It is essentially a syphon, con-

sisting of five feet of elastic tubing, one extremity terminating in a vulcanite bell-shaped opening guarded by a metallic grating, the other joining a silver stopcock, to which a cannula can be attached. A short distance from this extremity the continuity of the syphon is interrupted by a small glass tube, inserted for purposes of observation; a few inches higher still is an exhausting bulb, by which the air present in the instrument can be expelled prior to use. A semicircular canal of vulcanite protects the rubber tube where it passes over the edge of the vessel containing the solution for injection. The cannula is serpentine in form—following in this respect

FIG. 2.

Treves's pattern,—compressed a little laterally and embossed at the part where it should be grasped by the operator's fingers. It gradually tapers to a blunt extremity, at a distance of half an inch from which is an oval aperture for the transit of the vivifying fluid. This aperture can be closed by the pulp of the index finger whilst the point of the cannula is being inserted into the vein; as the finger is withdrawn the cannula is simultaneously pushed onwards; the possibility of the entrance of air into the vein, if this method be adopted with ordinary care, being certainly avoided. The cannula is grooved fifteen-sixteenths of an inch from its point, by which means it can be secured with a ligature and maintained *in situ* when fairly within the vein. Always mindful of the fact

FIG. 3.

that it must become the duty of every surgeon at some time or other to perform transfusion, like tracheotomy, entirely unassisted, or his patient must succumb. Fig. 3 represents an automatic retractor, which, being capable of almost instantaneous application, might often be very serviceable.

In conclusion, I beg leave to acknowledge many valuable suggestions I have received in reference to this syphon from Dr. Palfrey and Mr. Fenton-Jones, and to express the hope that by the substitution of simple for complicated methods of transfusion or intra-venous injection, every instrument devised for its performance being safer and surer in its mode of action than those which have preceded it, the operation will at length be elevated from the dazzling but delusive position it at present occupies to one of true utility to mankind.

#### NOTE ON THE OCCURRENCE OF CHOLERA-LIKE SYMPTOMS IN CASES OF URÆMIA.

By H. MALLINS, M.B., M.Ch.

THE perusal of the notes of a case of malignant cholera in THE LANCET of July 29th brought to the writer's recollection a case met with in India, in which many of the symptoms of cholera were induced by uræmic poisoning. The case was as follows:—

Ram Din, a grass-cutter of No. 2 Battery, Punjab Frontier Force, was admitted into the Battery Hospital, Edwardesabad, on the 20th of August, 1875, at twelve

<sup>1</sup> THE LANCET, 1877.

<sup>2</sup> Ibid., Sept. 16th, 1882, p. 436.

o'clock noon, in a state of complete unconsciousness, with severe vomiting and purging, the stools being of the rice-water character. It appears that he had been doing his work up till 9 A.M., and it was while cutting grass in the sun that he first fell ill. When seen the following morning (August 21st) his state was as follows:—Features pinched; surface quite cold to the touch. Tongue dry, with slight brown fur. Is now quite sensible, and able to get out of bed. Pulse 118, very weak; respiration 32; temperature 99° 2'. Passed a little urine yesterday evening. On passing a catheter the bladder is found to be quite empty. Is still purged, the stools being of the consistence of whey, dirty light brown in colour, free from smell, with floating flocculi. Voice is now fairly strong.—7.30 P.M.: Surface still feels cold. Temperature 99° 4'; pulse 120, very feeble. Abdomen tense and tympanitic. No urine in bladder. Has passed three stools since the morning, of thick consistence, faintly yellow colour, and slightly bilious odour.

August 22nd.—Lies in a drowsy state. Pulse 120; respiration 24; temperature 100° 1'. Has passed four stools during the night, of distinctly yellow colour. Urine still suppressed. He gradually became comatose, and died at 6 P.M., after a slight convulsive attack.

*Autopsy, half an hour after death.*—The chief morbid appearances observed were: Firm pleural adhesions on both sides of the thorax; extreme congestion of both lungs; the right ventricle distended with fluid black blood; walls of the left ventricle hypertrophied; well-marked atheroma of aorta. Kidneys weighed 4 oz. and 6 oz. 7 drs. respectively; both were diseased, the surface of each being uneven from the presence of numerous depressions, in the vicinity of which were several small projecting nodules; capsule adherent in places; surface of section pale and bloodless; no distinction between central and cortical portions; the pyramidal portion was for two-thirds of its extent occupied by a deposit of a light yellow colour and firm consistence, occurring in isolated masses of circular shape, and varying in size from that of a millet-seed to that of a pea. With the exception of decided vascularity of the mucous membrane of the large bowel, the intestines were healthy. Bladder firmly contracted and empty.

*Remarks.*—At the time of the occurrence of this case an outbreak of cholera was not unlikely, as cases had been reported from some stations close by. The sudden occurrence of the symptoms of unconsciousness, coldness of surface, feebleness of voice, vomiting, purging, the stools being of the rice-water character, and finally the suppression of urine, might have justified the diagnosis of malignant cholera, and in the absence of an autopsy the case would most probably have been reported as such. The examination, however, revealed a hopelessly disorganised pair of kidneys, and justified the conclusion that all the symptoms were due to uræmia. It will, therefore, be well to bear in mind the possibility of cholera-like symptoms being due to the diseased kidneys. It may be added that, contrary to expectation, no outbreak of cholera took place at the station where the subject of these notes died.

Watton.

## A Mirror OF

### HOSPITAL PRACTICE, BRITISH AND FOREIGN.

*Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.*—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

#### ST. THOMAS'S HOSPITAL.

TRAUMATIC NEUROMA OF ULNAR NERVE, WITH LOSS OF POWER OF PARTS SUPPLIED.

(Under the care of Mr. SYDNEY JONES.)

E. A—, aged ten, was admitted on March 10th, 1882. Twelve months before she had fallen on to a window, and wounded her left arm above the elbow on the inner side. The wound was sutured, and healed in a month's time, but a tender spot remained in the centre.

On admission she complained of a tender place above the left elbow, and on examination of this there was found to be

two inches above and a little posterior to the internal condyle, a scar about an inch and a half in length, running downwards and backwards; posteriorly to this there was another about three-quarters of an inch long. Beneath the principal cicatrix there was a very tender swelling in the course of the ulnar nerve, about the size of a horsebean, and presenting the character of a neuroma. Attached to this and a little below (a quarter of an inch) was a much smaller swelling having the same character. The left forearm was not so well developed as the right, this being most marked in the flexor and the inner sides; there was loss of sensation along the ulnar side of the hand, the whole of the little finger, and ulnar side of ring-finger. The movements of adduction of the hand and apposing of the little finger and thumb were imperfect, and she was unable to adduct or abduct the fingers. The muscles of the inner side of the hand and between the metacarpal bones were much wasted.

On March 18th, the patient being under the influence of ether, Mr. Sydney Jones made an incision about three inches in length over the neuroma and in the course of the ulnar nerve, and another at right angles to this. On dissecting down, the two swellings were found to be connected with the ends of the divided nerve, which were about two inches apart, a small fibrous cord connecting the two. The bulbous enlargements were removed. Both ends were stretched, the upper end to much greater extent and more easily than the lower, and were united together by means of three catgut ligatures. It was difficult to retain them in position on account of the tension. This was avoided by putting the elbow in a straight position. A drainage-tube was placed in the wound, which was closed by catgut sutures, and the limb, placed in a straight position, was encased in an antero-posterior plaster-of-Paris splint. The operation was conducted antiseptically.—19th: In great pain all day; pain described as of a jumping character. Temperature in the morning 101° 2', in the evening 103° 2'.—20th: Complaining of pain in the wound. In the morning, pulse 128, temperature 100° 6'; evening temperature 99° 6'. The wound was dressed; there was found some slight collection of pus between the stitches. Wound looking well; some stitches removed.—21st: A little pain, passing halfway down the forearm on the inner side; can feel in little finger when firmly touched.—24th: Wound re-dressed antiseptically; more pus between edges of wound; the transverse one not healed, and the one at right angles still open where the two join; one or two small sloughs came away; remaining stitches removed, and edges approximated by strapping. No elevation of temperature since the evening of the 20th.—26th: Less discharge; edges closer together; re-dressed under spray.—30th: Wound re-dressed; small slough separating at junction of the two incisions. Can feel when little finger is gently stroked; unable to abduct or adduct fingers.

On April 3rd the wound was re-dressed, and lasted well. On the 6th the antiseptics were left off, and zinc ointment substituted. A week later there was more power in the little finger, and she felt well where before there was either partial or complete loss of sensation.—On the 18th the wound was healed.

On May 5th she left the hospital cured.

On microscopical examination the bulbous enlargements of the nerve proved to be true neuromata, there being little fibrous tissue.

#### SUSSEX COUNTY HOSPITAL, BRIGHTON.

VESICO-VAGINAL FISTULA; COMPLETE CURE WITHOUT AN OPERATION.

(Under the care of Mr. JOWERS.)

C. P—, aged thirty-nine, was admitted on July 5th, 1882, into Bristol ward. The patient complained of being unable to "hold her water." Ten weeks before admission she was confined. The last confinement was her sixth, and was more difficult than the previous ones. Labour lasted forty-eight hours, and forceps were used. On the ninth day after the operation her urine dribbled away for the first time.

On admission there was a vesico-vaginal fistula at the very top of the anterior wall of the vagina. The opening was ragged, with cicatricial borders, and large enough to admit the tip of a man's forefinger. A female catheter was passed into the bladder, through the fistula into the vagina. The anterior lip of the os uteri appeared to have been destroyed, and the os uteri itself was left somewhat patent.

On July 7th a soft catheter was tied in, and the patient was kept in the prone position.—21st: Owing to obstinate diarrhoea the catheter has been withdrawn.—24th: The catheter has again been tied into the bladder to-day.—28th: The catheter has slipped out during the night. She affirms that much less urine runs away from the vagina, and also that she has passed several ounces voluntarily at one sitting.—31st: Catheter again tied in.

Aug. 4th.—Catheter removed this morning. She says that no urine runs away.—18th: As a small quantity of urine is again escaping the catheter is to be tied in once more.—20th: The patient is menstruating. The catheter has been removed. No urine is escaping.—25th: The patient was instructed never to empty her bladder herself. The urine is drawn off four times in the twenty-four hours. She keeps her bed. The sheets are never wet or stained.

Sept. 1st: She now gets up, and has complete control over the bladder.—6th: The patient was discharged.

Mr. Jowers remarked that he had never met with a similar case. In the text-books there is no such result recorded.

#### CASE OF CYSTIC BRONCHOCELE CURED BY SETON.

(Under the care of Mr. JOWERS.)

W. B—, aged twelve, was admitted on Oct. 6th, 1881, into the Chichester ward. The patient had a swelling in the neck. He had had this for four years. It was situated in the front of the neck on the left of the median line. It occupied the position of the left lobe of the thyroid gland. It rose and fell during deglutition. It was about the size of an orange, and had the feeling of a cystic body; it was not translucent. The right lobe of the thyroid gland was not enlarged. The swelling did not pulsate; it was neither painful nor tender. Patient's general health was quite good.

On Nov. 10th patient was put under chloroform. A small trocar and cannula were thrust into the tumour; two or three teaspoonfuls of dark coloured fluid ran out. Tincture of iodine and water, half and half, was injected. The trocar was then thrust into another part, and about the same quantity of similar fluid ran out. This cyst was likewise injected.—11th: Patient has had no pain.—14th: The iodine injections have had no apparent effect.

Dec. 1st.—The swelling having regained its former size, the tapping has been repeated and undiluted tincture of iodine injected.—3rd: The iodine has not caused any inflammation.

Jan. 1st.—The injection of iodine has been tried a third time with no apparent effect.

Feb. 1st.—Four pieces of thick silk have been passed through the tumour by means of a post-mortem needle; there was no hæmorrhage.

April 1st.—Since the last note there has been a marked decrease in the size of the swelling. On some days there is nothing to be seen, and then again it will become obvious. Seton continued.

May 12th.—As nothing abnormal has been observed of late, the seton has been removed.

June 21st.—The sinus left by the seton has long healed. The swelling has not returned. Patient discharged.

For the above notes we are indebted to Mr. B. Scott, house-surgeon.

#### NEWCASTLE INFIRMARY.

EYELASHES IN THE ANTERIOR CHAMBER OF THE EYE,  
THE RESULT OF A STAB.

(Under the care of Mr. WILLIAMSON.)

PETER McD—, a schoolboy, eight years old, was admitted on account of a lacerated wound of the foot, caused by the wheel of a coal-truck. His left eye was bandaged when he was admitted, and he explained that a fortnight previously his brother had stabbed him in the eye with a penknife during a quarrel. There was but slight inflammation and very little increase of vascularity in the ciliary region. On the front of the cornea in the area of the pupil there was an irregular cicatrix about the eighth of an inch long, and inside the anterior chamber were what appeared to be six or seven hairs lying vertically. The ends of some of them were engaged in the iris, without seeming to cause any irritation.

Four days after admission the child was chloroformed.

Mr. Williamson made an incision at the upper part of the cornea, and excised a piece of the iris. The hairs were then drawn out with a pair of fine forceps; one hair that escaped the forceps was caught by a Tyrrell's hook. All went on well after the operation, and the lad has now good sight with the injured eye.

Under the microscope the hairs were found to taper to a point at one end, and to have a root at the other. They were about the length of the eyelashes. The lid was carefully examined for a gap in the line of lashes, but none was found. Probably the knife was a blunt one, and caught the lashes about the middle, doubling them up and drawing them out by the roots. They would then be carried on the end of the blade into the anterior chamber, remaining there when the knife was withdrawn.

It is remarkable that the hairs caused so little irritation, although some of them actually pierced the iris.

## Reviews and Notices of Books.

*On the Climate and Fevers of India.* The Croonian Lectures for 1882. By Sir JOSEPH FAYRER, K.C.S.I., F.R.S. London: J. and A. Churchill.

IN the present volume Sir Joseph Fayrer has supplied the deficiency we regretted in his work on "Chronic Dysentery and Tropical Disease," a deficiency which in our opinion detracted considerably from its value as a complete treatise on the subject which it discussed. We are the more interested in this matter since year by year the study of tropical disease becomes a greater necessity for every practitioner in this country as the means of intercommunication between the various regions of our vast empire become more extended and more rapid. Sir Joseph Fayrer is therefore assured of an intelligent and interested audience to listen to whatever he has to tell them of diseases that are coming more and more under observation in this country. The work opens with some valuable statistical details, chiefly relating to the distribution of fever in different parts of India, in connexion with the physical geography of the various districts, climate, rainfall, irrigation, habits, food, &c., and then passes to a consideration of the etiology of tropical fevers generally. The origin and nature of malaria are discussed at length. This subtle foe, as far as England is concerned, has long since, like scurvy, been banished to a pathological limbo, and not without reason, since in an open form it may be said almost to have ceased to exist, except in a few—and it appears these are becoming less and less year by year—ill-drained and poorly-cultivated districts. Dr. Stephen Mackenzie's statistics on this point, quoted by Sir Joseph Fayrer, are extremely interesting. From these it appears that in the London Hospital, which from its size and position is well qualified to afford information, in the year 1770, of 1483 in-patients there were 21 cases of intermittent, with 1 death; in 1780, apparently an unhealthy year, there were among 1617 in-patients 59 cases of intermittent, but only 1 death; whilst in 1870, with 5218 in-patients, there were only 2 cases; and in 1880, with 6312 patients, there were 14 cases, but no deaths. The question of malarial poisoning, however, has been revived of late, since many eminent authorities believe that, "though scotched, it is not killed," and that the disease still frequently manifests itself, though in an insidious and incompletely developed form. The chief interest, however, connected with the subject of malaria relates to the probability of its having been caused by organisms. The subject has been investigated by Klebs, Tommasi Crudelli, and others, who have all demonstrated the presence of organisms in the blood of ague patients and the soil of malarious districts. Dr. L. Aitken, of Rome, has in this country shown what he regarded as specimens of bacillus malaria, and Dr. MacMunn, of Wolverhampton, discovered a bacillus in the blood of a young African traveller during the cold stage

of an intermittent fever. Further observations are required, however, before the hypotheses advanced can be finally accepted. Sir Joseph Fayrer states the case as it at present stands clearly and impartially. The modes of action of malaria are next discussed, and much valuable information added to our store of knowledge. In speaking of the respective action of air and water in distributing the poison, he makes no mention of the interesting fact to which the late Professor of Military Hygiene at Netley first drew attention—viz., that the troops quartered at Tilbury Fort have generally suffered more or less from ague, whilst the men at the railway station, the coastguard, and their families, just outside the fort, never suffer from malarial poisoning. The soldiers drink rain-water stored in tanks, the others water from a spring.

The second lecture is chiefly devoted to a clinical description of paroxysmal fevers of malarial origin, and is an admirable summary of the chief features of the disease in its various manifestations. The temperature-charts of the different types will be found especially useful by practitioners in this country for purposes of reference and comparison. The author, however, hardly touches the subject of the sequelæ of the disease, and we regret that he has not done so, as it would have greatly added to the value of the work for English readers. At present the best summary we have is the interesting clinical lecture delivered by Dr. Murchison shortly before his death, and which appeared in our columns on May 2nd, 1879. Sir Joseph Fayrer quotes Verneuil as showing the occasional occurrence of glycosuria with or after malarial fever. This, however, is no new fact, since Prout made a similar observation forty years ago.

The third and last lecture deals with the continued fevers of India, and its chief interest consists in the discussion of the question of the etiology of enteric fever in that country—whether the disease which in temperate climates is universally acknowledged to have one specific origin, may not in the tropics be derived from others. As Brigade-Surgeon Marston has well put it, there apparently exists two forms of enteric fever in India, which cannot however be clinically or pathologically differentiated: one not depending on any specific poison generated in the intestines of one person and conveyed to another through some vehicle; the other where the cases can be traced to such cause through fouled air, water, &c. The subject still awaits solution, and it is a question whether a more searching investigation may not prove that the two forms, apparently so alike clinically, may not take a pathological departure in the character of the intestinal lesion. Thus Dr. Wall, of Calcutta, has described an ulceration, by no means selecting the site of Peyer's patches, which occurred in cases of "remittent;" whilst in the post-mortem appearances recorded by Röderer and Wagler in cases of so-called "typho-malarial" fever, the bulky tumefaction, ulceration, and sloughing of Peyer's glands are not recorded as having been present. Nor is the evidence brought forward to show the impossibility of infection from specific causes perfectly convincing. It is difficult, for example, to understand why the fact that cases of enteric fever occur in Europeans speedily after arrival in India, often in districts previously only occupied by natives and where there is absolutely no evidence of any previously existing filth contamination, should be considered as conclusive against the possibility of disease arising from specifically infected excreta, since the seeds of the malady might easily have been brought by the new comers from their last station.

It now remains, in bringing this notice to a conclusion, to thank Sir Joseph Fayrer for the lucid and graphic manner in which he has brought the subject of these lectures under our notice. He has produced a work which will long be

consulted as a standard authority on the subject on which it treats, and it will eventually take its place among the medical classics.

*Spon's Encyclopedia of the Industrial Arts, Manufactures, and Raw Commercial Products.* Edited by CHARLES G. WARNFORD LOCK, F.L.S. Two vols. pp. 2142. London: E. and F. N. Spon, 1882.

THIS splendid work forms a fitting companion to the Dictionary of Engineering published by the same firm. The editor must be congratulated on the help he has received from a large staff of contributors well known in the scientific world, and on the great judgment and skill he has displayed in a task of no ordinary magnitude.

The plan of the work is explained very clearly in the preface, from which we should quote largely if space permitted. "The most notable and important feature is undoubtedly represented by the Raw Commercial Products." These are arranged "in groups according to their similarity of origin, character, and application." Thus we find as separate headings, drugs, dye-stuffs, fibrous substances, narcotics, oils and fatty substances, resinous and gummy substances, spices, starches, sugar, tannin, and timber, with many others. This arrangement presents many advantages, and is on the whole the best, although it is attended with occasional difficulty. Tea, coffee, and india-rubber, for instance, occur under two different headings, and were it not for a tolerably copious index it would in some cases be rather difficult to find the information sought for.

Manufactures and industries form another important portion of the book. We may mention as first-rate articles those headed "Bleaching," "Coal-gas"—evidently by Mr. Greville of the Commercial Gas Company,—"*Manures*," with elaborate details in regard to the modern artificial fertilizers, "*Soap*," and "*Glycerine*,"—which are merely examples drawn from a long list. The articles on textile industries are also very good.

The subject of adulteration is somewhat imperfectly dealt with. The deficiency is not of great importance, as many good text-books are available; but we think it would have been better to have included more of the methods of analysis which have come into use since the passing of the Food and Drugs Acts. The adulterants most frequently used are, in general, sufficiently described.

Among the articles which will be most valuable to our readers we will select a few of the most important, as they serve as fair illustrations of the general character of the work. "*Alcohol*" is one of the first. It contains an account of the mode of preparation and peculiarities, not only of the common but also of many of the less common spirits in use, such as absinthe, arrack, and kirschwasser. The Russian liqueur, kümel, is, however, omitted. "*Beverages*" include aerated waters, tea, coffee, cocoa, beer, cider, wine, and water. There is much useful information in regard to the deterioration of wine. "*Drugs*" is an excellent article. It occupies nearly thirty large and closely printed pages, and gives information about many drugs but little known in this country, such as Ajowan, bael, and the Bolivian coto. The account of the cinchona is very full and interesting. "*Oils and Fats*," divided into animal, fixed, vegetable, and volatile, is also a very useful article, as is that headed "*Resinous Substances*," under which india-rubber, tar, and turpentine are included.

If we add that much attention has been paid to the nuisances arising from chemical manufactures and the means of remedying them, and that waste products are in general well described, our readers will see that the new "*Encyclopedia*" is one without which, to use the time-honoured phrase, "no gentleman's library, certainly no medical library, is complete." The book is fully and

admirably illustrated, and is printed well and on good paper. So valuable a work will be sure to reach a second edition before long; and we venture to suggest to the editor that it might easily be improved by the insertion of a greater number of well verified analyses of raw, waste, and manufactured products.

*Notes on Surgical Treatment and Minor Operations.*

Specially designed for House-Surgeons and Students. By THOMAS F. HOPGOOD, L.R.C.P., M.R.C.S., Surgeon to the Sunderland Infirmary, &c. London: Baillière, Tindall, and Cox. 1882.

We are informed in the preface that this work is intended "as a guide to every-day work of house-surgeons and students." A few quotations will show that the above description of the book is not warranted by the character of its contents. The grammatical construction is often peculiar. Thus on the first page we read: "..... dislocations, which can be replaced easily, should be effected at once." A fluid recommended for injection into the sac of an hydrocele is one composed of "equal parts of iodine and water." On page 24 "house-surgeons and students" find themselves addressed in these words: "If you have stricture it may either come under the surgeon's or house-surgeon's care." To pass a French catheter "all you have to do is to catch hold of the penis with the left hand, and drag it well forwards, and pass the instrument by thrusts, at the same time giving it a rotatory motion." On page 16 hot fomentations are stated to prevent suppuration, but hot linseed-meal poultices to hasten it. Again, on page 13, we read that after a large abscess has been opened "in most cases stimulants are necessary." "As a rule, stimulants do good when the pulse grows less frequent, the tongue cleaner, and the temperature lower." We learn also that the stomach-pump "may be used in stricture of the œsophagus, or in mania." In taking a skin graft "a small piece of skin is caught hold of with the artery forceps, and then divided, taking care to remove no fat with it." We will complete these quotations by an extract which is Mr. Hopgood's advice to "house-surgeons and students" when asked to give a prognosis in a case of burn. "If the burn be at all severe it is best to give a guarded opinion, by saying the probability is they will either live or die; but the possibility is that they may recover or not, according to the circumstances of the case—namely, if the chest is burnt the prognosis is not so favourable as if the legs; then, again, the age, constitution, and severity must be taken into account."

The absence of any kind of index, and of any alphabetical or other simple arrangement of the matter of this "guide," is one of the striking features of the book.

*A Price List of Surgical Instruments, Apparatus, Appliances, &c.* Manufactured and sold by JOHN WEISS and SON. London: M. S. Rickerly. 1882.

*Catalogue of Surgical, Physical, and Physiological Instruments, Microscopes, Medical Appliances, and Sundries.* By BRADY and MARTIN. Newcastle-upon-Tyne. 1882.

IN revising their catalogue of instruments, Messrs. Weiss and Son have added to it the price of every article, which will be a great convenience to their customers. Unlike many similar catalogues, it contains no illustrations; but this want is to be supplied by a separate book of illustrations, which will shortly be issued, and make the catalogue complete.

Messrs. Brady and Martin supply a priced and illustrated catalogue not only of surgical instruments and appliances, but also of microscopes and all requisites for modern histological work, even down to the various staining reagents and mounting media. Physiological instruments, such as the kymograph, tenometer, and onkometer, are also to be found, along with museum jars and various other appliances

used by medical men in their various pursuits. These additions have materially increased the value of this catalogue.

## CUTANEOUS INJECTION.

*To the Editor of THE LANCET.*

SIR,—We are constantly reading of experiments on animals, showing how death is produced by the injection under the skin of fluid containing different kinds of micro-organisms, but might not the gentlemen conducting these valuable experiments greatly enhance their value by trying to discover an antidote to these poisons? If they could only be induced to inject into the veins of the animal about to have the poisonous fluid introduced some of the numerous antiseptics or germicides, they might possibly make the discovery that one of them possessed the remarkable and useful property of converting the blood into a fluid in which the development of the poison could not proceed, and the animal would not die. We have all heard that the injection of a solution of permanganate of potash into a vein immediately after the introduction into the system of the rapidly fatal cobra poison prevents that poison from having its usual fatal consequences, and doubtless it would have the same result if injected immediately before the bite of the cobra. Again, Dr. Fontaine, Bar-sur-Seine, has had the most remarkable success in his treatment of diphtheria by giving his patients sulphide of calcium until the breath and skin exhale the odour of sulphuretted hydrogen. And even if the experiments on animals, such as I suggest, should fail to discover an antidote or germicide powerful enough to counteract the poisonous effects of the micro-organisms, which in a concentrated form are injected under an animal's skin, it might still be possible for those of our surgeons who have a large and sad experience of blood-poisoning, or for those practitioners who have numerous cases of zymotic diseases constantly under their charge, to move in the track of those gentlemen who have been successful in combating the deadly cobra poison and the too often fatal diphtheria.

There are several antiseptics besides permanganate of potash with which the blood might be saturated, either by injection into a vein or by small and frequently repeated doses—for example, eucalyptus, sanitas, the sulphides, the carbolates, the salicylates, &c., and I trust I am not too sanguine in believing it quite possible that carefully conducted experiments might discover in some of these a means of destroying or rendering harmless those other zymotic poisons that play such terrible havoc with human life.

I remain, Sir, yours truly,

Snaresbrook, Sept. 13th, 1882.

WALTER SCOTT, M.B.

## IRIDECTOMY KNIFE.

*To the Editor of THE LANCET.*

SIR,—I wish to call the attention of ophthalmic surgeons to a new-shaped iridectomy knife which I have devised. It is easily made out of the old-fashioned knife by having the point ground down, and the cutting edge made semi-circular like a cheese-cutter. It is used by a sideways motion until the sclerotic is cut through, and not by transfixion; and the advantages I claim are the absolute immunity from danger of wounding the capsule, and also that the wound, being almost at right angles to the sclerotic, allows of the iris escaping at once. Messrs. Weiss have the pattern, and have made me several. It can also be used for linear extraction, for which I first had it made, and it succeeds very well; but in this country, where there is a difficulty about sharpening knives, it does not last so long as a straight knife.

I am, Sir, yours truly,

GEO. HY. C. HALL, Surgeon, I.M.D.

Eye Hospital, Allahabad, India, Aug. 20th, 1882.

ROTUNDO LYING-IN HOSPITAL. — During the year ending April 1st last, 1819 patients were admitted to the labour wards, which with 29 previously in the hospital made a total of 1348 under treatment. Of these 12 died, and the mortality, deducting 218 admitted to the lying-in department, but discharged, not being then in labour, was 1.08 per cent.

# THE LANCET.

LONDON: SATURDAY, SEPTEMBER 23, 1882.

NEARLY twenty years ago, Dr. BRISTOWE and Mr. HOLMES, in a Report to the Privy Council on Hospitals, discussed many of the conditions required for the hospital treatment of infectious diseases. But since that time the principle has been largely accepted that infectious persons should be treated in hospitals altogether separate from those devoted to non-infectious cases, and legal powers have been given to, and utilised by, many sanitary authorities for the erection and maintenance of a number of institutions for the isolation and treatment of infectious persons, and for the prevention and limitation of this class of disease among communities. Knowledge and experience of such hospitals have therefore considerably increased, but the lessons taught by the success of some institutions and the failure of others could only be fully learnt by a comprehensive inquiry into the history of all.

The intention of the Local Government Board to collate the experiences of sanitary authorities who had provided their districts with hospitals has now led to the issue of a volume which will be welcomed not only by sanitary authorities, but by all health officers and architects interested in or concerned with the making of hospital provision for infectious diseases. That the work was entrusted to Dr. THORNE THORNE is good evidence of the importance attached to it by the Local Government Board, and is a guarantee of the thoroughness and trustworthiness with which it has been carried out.

In the first instance a circular letter was addressed to the various authorities, inquiring as to the nature and amount of the hospital provision which had been made by them, with the result of showing that 296 out of 1593 sanitary authorities in England and Wales had made some sort of provision. This inquiry was useful as indicating the districts which were best worth visiting, and these were selected as representing certain classes in which there had been either failure to secure isolation, or in which a temporary or permanent hospital had been provided by a single authority or by combination with other authorities, or where arrangements had been made for the admission of infectious persons into an existing infirmary. Altogether sixty-seven hospitals were visited, and these, varying very greatly, have afforded Dr. THORNE an ample opportunity for considering all details of hospital construction, as well as the requirements of different districts.

Dr. THORNE gives an interesting account of the manner in which many of the hospitals came into existence, and how they are often dependent upon some previous outbreak of typhus or cholera for which provision had to be made; and he states very clearly that if a hospital is hurriedly built under the influence of panic, it is often not ready for occupation until the immediate cause of its erection has passed by; it provides accommodation of a very indifferent sort, and it fails, almost without exception, to meet the permanent

requirements of the district. It is obvious that when a hospital is wanted for one outbreak of disease it will in all probability be required for others, and the proper course for a sanitary authority to follow is always to have ready for immediate use the accommodation that will be needed.

Dr. THORNE'S conclusions with regard to the site of infectious hospitals are well worth the consideration of all authorities who may in the future have to provide for their districts. He found that distance from the patient's home alone was not so much an obstacle to the use of a hospital when the sick person's welfare alone was concerned, but that when this interfered with the visits of friends it often led to the sick remaining in their own homes. Again, the removal from one district into another sometimes proved a difficulty, especially when the patient and his friends were not familiar with the region in which the hospital is situated. Indeed, the whole Report bears evidence of the extent to which sentiment influences the amount of use to which a hospital is put, and this is no matter for surprise when it is recollected that families are asked to entrust to strangers the care of some member who at the time is absolutely dependent upon those about him. This is a point which appears in several parts of the Report, and is one which should be carefully borne in mind in all matters relating to the construction and management of such institutions. For this and other reasons Dr. THORNE recommends that the hospital should be situated in the district for the use of which it is intended. If for a town, it should, under ordinary circumstances, not be more than two miles away, and if for a rural district not more than four or five miles from the more populous portions. In choosing the site, regard is of course to be had to the necessity which might in the future arise for the further extension of the building; while the situation of the hospital on the site should, if possible, be such as to admit of the opposite windows of the ward pavilion facing somewhat to the south of east and to the north of west. The whole is to be enclosed by a substantial wall, to prevent any improper communication between the inmates of the hospital and the outside public.

The more efficient hospitals have made provision for two diseases and for two sexes suffering from each; they have therefore consisted of a central administrative block, four pavilions, and out-buildings containing laundry, mortuary, &c. The administrative buildings have always been somewhat in excess of the requirements of the permanent buildings, so as to enable the hospital to bear, without inconvenience, the erection of temporary wards when any special occasion arises. They are separated from the ward pavilions, with which they sometimes communicate by means of a passage well ventilated, by being altogether open or with cross windows. The use of iron and wood for the erection of pavilions has not proved satisfactory. Wards thus constructed have been found too hot in summer and too cold in winter; while, so far as economy is concerned, Dr. THORNE is of opinion that if they were properly constructed to overcome this objection their original cost would either equal or exceed that which would be incurred by the erection of ordinary brick buildings.

The best hospitals are all arranged on the pavilion principle, this plan offering far better opportunities for classification of diseases and ventilation of wards than any other,

and the arrangement of the buildings in the most efficient hospitals was not found to accommodate more than twenty patients on an acre. Where accommodation has also to be provided for small-pox, Dr. THORNE recommends that the pavilion for this disease should be more separated from the rest of the hospital than is necessary for the other fevers, and that it should contain sleeping accommodation for nurses.

The construction of ward pavilions is fully dealt with, the amount of floor, wall, and window space for each bed discussed, and the best methods of ventilating and warming indicated. Much difficulty has been found in comparing the cost of different methods of construction, but a very instructive table accompanies the Report, and shows the cost per bed of some of the best permanent hospitals.

Dr. THORNE goes carefully into the question of the advisability of general hospitals receiving cases of infectious diseases at the cost of the sanitary authorities, and expresses a strong opinion against this plan. He quotes the Pendlebury Hospital for Sick Children as the one best arranged for separating infectious from non-infectious patients, and points out that even in this institution extension of disease among the latter has from time to time occurred, and that where small-pox is concerned nothing but a complete severance of the two parts of the institution, both as regards wards and administration, gives security against such accidents.

An important lesson is taught by the failure of some sanitary authorities to secure the isolation of infectious cases. The failure, as a rule, depended upon the erection of the hospital at a period when it was too late to answer the purpose of isolating the first cases of an outbreak, or when for some reason or other it was not well adapted to the needs of the district. But with one single exception, "no hospital adapted to and kept in readiness for the reception of the sick was found which had not done some good in staying the spread of infection."

With regard to the different infectious diseases, Dr. THORNE found the greatest efforts had been made by sanitary authorities to isolate small-pox, while scarlet fever did not appear to be regarded as deserving so much care; but, as he points out, scarlet fever is the disease for which isolation is most constantly and most urgently needed. Dr. THORNE places small-pox next in the order of those diseases which need isolation, but admits that typhus has in some towns prior claims to small-pox in this respect. Dr. THORNE does not enter into the question of how far it is fair to tax for the benefit of the unvaccinated the ratepayer who chooses to protect himself against small-pox by resorting to vaccination; but there is no doubt that the cost of providing for the isolation of small-pox, a cost which is already large, and likely to be much increased if the teaching of Mr. POWER's report on the Fulham Hospital is to be acted on, will soon make the hospital provision for this disease a very serious undertaking. Diphtheria and measles have been occasionally isolated, but there are good reasons why sanitary authorities should find it difficult to undertake such duties with regard to the latter disease.

Dr. THORNE'S inquiry into the results of compulsory notification of infectious diseases was conducted at a period too early for any large amount of evidence to be forthcoming, but he expresses the opinion that "where a suitable hospital exists, such notification, if general, cannot fail

greatly to favour the object in view." In several districts he found that a notification of infectious diseases occurring amongst children attending elementary schools has proved useful in facilitating the isolation of such cases. A point particularly worthy of notice at a time when the arrangements for the isolation of infectious cases in the metropolis are under consideration is the necessity which was everywhere found for the separation of hospital provision for infectious diseases from all association with the relief of paupers. Hospitals for sanitary purposes must be altogether under the control of sanitary authorities, and although under certain conditions the admission of paupers into these institutions does not appear to interfere with their usefulness in other respects, the greatest care is needed to prevent the pauper, while in the hospital, bearing evidences of his social condition.

Many other points are considered which must be left for further notice, particularly the evidence as regards the influence of these institutions on the neighbourhood surrounding them. The Report is undoubtedly the best work on hospitals for infectious diseases which we possess; it contains an excellent account of the different institutions which Dr. THORNE visited, and is very fully illustrated with a number of plans showing their construction and arrangement.

THERAPEUTISTS have paid little attention to the changes which drugs, administered by the mouth, undergo in the digestive organs before they are absorbed, except in the case of those inorganic substances which are given for their direct effect on the gastric mucous membrane. The practitioner gives other drugs, for the most part, without considering how far they may be altered before they leave the alimentary canal. He is guided by what is known of their subsequent action on the system and of their effect in disease, and he is no doubt thus guided, in the main, correctly. Nevertheless the subject is not an unimportant one, since the influence of the digestive ferments on drugs must, or rather should, determine the time of their administration in relation to the process of digestion. At present careful attention is paid to this point in choosing the time at which to administer those therapeutic agents which are designed to have a direct action on the stomach, but, as regards others, it is not considered except in so far as it influences the rapidity of their absorption. No facts, indeed, have hitherto been available for the guidance of the practitioner on this important subject. It is only since the processes for artificial digestion have been perfected that it has become possible to ascertain such facts, and the subject is certainly worthy of the attention of the pharmacological experimentalist.

These remarks are suggested by a series of experiments of this nature, although with a different object, which were described at the recent meeting of the Pharmaceutical Conference by Mr. GEORGE BROWNE. This gentleman has endeavoured to ascertain to what extent the digestive ferments may be made available for the production of preparations of various drugs. The question necessarily involved that of the extent to which their active principles suffered in the process. The constituents of rhubarb were found to be extracted, with remarkable completeness, by treating an infusion first with an acid preparation of pepsin,

and then, after neutralisation, with an alkaline solution of pancreatin. The former extracted 47 per cent. of the rhubarb, and the latter 13 per cent. more, leaving only a residue of cellulose and earthy salts. Infusion of calumba, prepared with boiling water, and passed through a similar process of digestion, gave somewhat similar results; only spongy cellulose, associated with a trace of berberia, was left. Cinchona and opium, on the other hand, behaved differently; the gummy and extractive matters were dissolved and retained in solution, but a considerable quantity of the alkaloids was left behind. About half the cinchona and two-thirds of the opium were dissolved. The cinchona tannin was destroyed in the process of digestion, and failed to precipitate gelatine. The arabin of gum acacia remained apparently unaffected by the process, but a peptonising change was wrought upon some other constituent of gum, possibly a nitrogenous impurity. The mucilages obtained from Irish and Iceland moss were also tested, since they hold an intermediate position between foods and medicines. The alkaline extract of the pancreas seemed to exert very little action on Irish moss, although the proteolytic ferment of the pancreas, extracted with acids, soon destroyed the viscosity of the mucilage, and divided the jelly into soluble and insoluble portions. Iceland moss behaved somewhat differently. A jelly of it became flocculent when acted on by the gastric ferment, and under the influence of pancreatic extract deposited yellowish white flakes, consisting of non-crystalline masses, possibly peptic acid.

Of more direct interest, however, is the action of the digestive ferments upon definite organic compounds. The acidulated extract of the gastric juice decomposed a watery solution of salicin very slowly and imperfectly, but the pancreatic ferment split up the salicin into saligenin and glucose. Jalapin remained intact after digestion with the pepsin solution, but pancreatic digestion withdrew from it a copper-reducing substance. Neither process had any influence upon santonin. A solution of tannin, treated with the acid pepsin solution, became turbid, but the turbidity disappeared after the addition of a little more hydrochloric acid, and prolonged digestion seemed to have no further influence. The pancreatic extract, however, quickly rendered tannic acid incapable of precipitating gelatine, as it had been found to do in the experiments with cinchona bark, apparently by converting it into gallic acid. The experiments of Mr. BROWNEN go no farther, but he has evidently opened a field of considerable importance, in which other observations will probably yield results of considerable practical value to physicians as well as to pharmacists.

In our Local Government Department we give an abstract of three reports on Diphtheria which have been presented to the Local Government Board, and which exemplify in a striking manner the difficulties which are connected with investigations as to the etiology of this disease. The outbreaks occurred at King's Lynn, Sale, and Sutton-in-Ashfield. In two instances the disease appeared in low-lying localities; in the third on a plateau at an elevation of 500 ft. above the sea. The soil on which the affected places stood differed as widely as possible—in one instance consisting of the alluvial deposit of the river Ouse, in another

of the magnesian limestone and the new red sandstone. The method of infection, though at times due to personal communication, was certainly not so in all cases, and even the fact of school assemblage, so commonly believed to be a principal factor in the incidence of the disease upon young children, entirely failed in one marked instance to account for that special incidence. Various faulty sanitary conditions affecting the housing and other surroundings of the patients were discovered, and they are discussed in detail. They related to pollution of water, exposure to contaminated air from drains and privies, and at times to conditions of filth in-doors; but no one of these conditions could be regarded as common to the majority of the dwellings attacked, nor even to those where the initial cases occurred; indeed, in one town it was evident that the poorest and the least cleanly parts of the district were certainly not more affected than the more healthy localities inhabited by the well-to-do and the affluent. The three outbreaks either commenced or reached their maximum of intensity in the latter part of 1881, and if any common meteorological condition could be regarded as having brought them about, it might have been expected that they would have borne some resemblance to each other in their essential characteristics. But this was by no means the case. In one instance at least, the early attacks were apparently of so trivial and uninfected a character as all but to escape notice, and the more severe attacks which followed did so with increasing severity, giving some support to the view enunciated by Dr. THORNE THORNE before the Epidemiological Society as to the "progressive development of the property of infectiveness" in this disease. In other instances, however, each group of attacks commenced with genuine diphtheria marked by all its characteristic signs, and followed by the typical paralytic and other lesions. The outbreak at Sutton-in-Ashfield is further interesting by the fact that it seems to have been inextricably mixed up with scarlet fever. These two diseases certainly appeared side by side, deaths occurring almost simultaneously in the same house from both diseases, and, as far as Dr. PARSONS could learn, there appeared to have been so little chance of faulty diagnosis that he himself speaks of the one disease as apparently contracted from the other. Whether these two diseases can possibly have some mutual or common causation is certainly as yet undetermined, but there is something so indefinite about diphtheria as to make it quite possible that the poison to which it is due has not yet acquired the stability possessed by the special infection of some of the other specific fevers, and that it hence at times acquires characteristics resembling other allied diseases, whereas on other occasions these do not manifest themselves.

The etiology of diphtheria is as yet involved in so much obscurity that the record of any painstaking investigation into the subject is of considerable interest, and no piece of work which has been carried out by Dr. AIRY in his numerous researches as to this disease is more typical of the sort of inquiry which is needed than that relating to the epidemic at King's Lynn. Indeed, intending investigators of the subject would do well to study this report, and so to make themselves acquainted with the special and detailed character which their labours must assume if any trustworthy conclusions are to be drawn from them. This will

be the more necessary because it so often happens that bare statements recording, for example, the healthiness or unhealthiness of a locality or of a house affected are entered up in reports as to diphtheria, whereas the views of one investigator as to what constitutes healthiness or the reverse differ entirely from those of a co-worker in the same inquiry, and at times no indication whatever is given as to the nature of the alleged unhealthy circumstances, whereas these may vary as widely as do the different conditions of filthiness about houses which are associated with prevalence of enteric fever on the one hand and of typhus on the other.

From Dr. AIRY'S report on the diphtheria prevalence in King's Lynn, it is evident that every separate circumstance which could have led to the disease received the minutest inquiry, and one by one the conditions of water-supply, excrement-disposal, sewerage and drainage, food-supply, and other matters, are considered and set aside as not sufficing in themselves to explain the problem under investigation. Some of these conditions doubtless favoured the spread of the infection, but it is important to distinguish between the cause of initial attacks and circumstances favouring the subsequent propagation of the disease. This point being held in view, the influence of epizootic disease, of rainfall and damp, and of other circumstances, are also investigated, the question as to the cryptogamic origin of the disease being discussed in connexion with the mould of some fungic mycelium found in several of the infected houses. Failing, however, any satisfactory explanation of the question as the result of this line of inquiry, Dr. AIRY records a fact well worthy of note in connexion with the view often held, and also to some extent supported by himself, to the effect that diphtheria is in some obscure way favoured by dampness, especially in marshy districts. At King's Lynn considerable excavations had been in progress, both in the old river bed and in certain foul deposits along minor streams, just before the onset of the disease, and the direction of the wind was such as to carry into the town any emanations arising from this source. Long-buried germs of some indigenous diphtheria-causing microzymes may, he surmises, have been carried in this way amongst the population affected, the process being aided by conditions of season and of atmosphere favourable to the maintenance of their vitality and to their distribution. Further research can alone determine the value of this fresh hypothesis, but it is at least interesting to note in connexion with it that Dr. PARSONS, as the result of his inquiry at Sale, having eliminated all the more generally recognised causes of infectious disease, deems it conceivable that in the vicinity of the Mersey marshes diphtheria may perhaps be brought about by some living micro-organism, the development of which is nurtured in a moist and porous subsoil contaminated with decaying sewage and other matter. Certain it is that the field of research as regards the etiology of diphtheria is still open, and that no subject ever stood in greater need of being investigated in its minutest details, and with strictly scientific accuracy.

THERE are domestic troubles at the Macclesfield Infirmary, and an appeal has been made to the public through the local lay papers. We are not sure that this was the most

prudent or dignified mode of procedure with a view to secure the redress of such wrongs and grievances as those set forth by the resident medical officer. However, let that pass. It is not for us to comment, or to form a judgment, upon matters and questions which have not been submitted to the censorship of the professional press. Without noticing the personal issues raised, there is abundant evidence to show that the domestic discipline of the infirmary at Macclesfield is in a most unsatisfactory state. Past and present resident officers of that institution seem to be agreed that the matron is the ruling authority of the establishment. If this be the fact there is not a word to be said in defence of the organisation. A woman at the head of a medical institution renders it an anomaly; and members of the profession who desire to preserve their self-respect should retire from an establishment thus constituted. It is, as we have repeatedly and strongly insisted, essential to the welfare of a medical institution that it should be under the control of the medical men attached to it. The only legitimate position of a matron in such an establishment is that of a house-keeper, and it should be her duty to carry out the instructions of the medical staff as represented by the resident medical officer.

Unhappily the great majority of hospitals and infirmaries throughout the country are constituted on a wrong basis. Certain benevolent citizens, anxious to relieve the sufferings of a local population, found an institution, endow it, or place it in a position to be supported by subscriptions, and then offer medical appointments to the practitioners of the neighbourhood. This is beginning at the wrong end. It is like providing a suit of clothes and finding a man to fit them. A medical institution should be medical all through. To establish a lay authority and employ professional men as servants or agents in the work of treating the sick is to create an utterly unworkable system. The primary object of a hospital is to cure the sick; the purpose of affording the poor a shelter and necessary comforts while they are under treatment is secondary. It is for those who undertake the cure of the sick to determine how they shall be housed and fed and tended during illness, because these services are subsidiary, and ought to be made tributary, to the main purpose—namely, cure. Committees of laymen do not easily recognise the principle we have laid down, or if they do they refuse to adopt it as the guiding law of their conduct, and the only basis of a satisfactory organisation.

It may appear, at first sight, that the troubles which have occurred at Macclesfield, being chiefly of a domestic character, scarcely stand in the same close relation to faults of constitution as other troubles elsewhere; but it will be apparent on consideration that if a matron can in any matter dictate to the medical officer of an institution, she must be wholly out of her place, and a ruling power instead of an upper servant, which the matron of a hospital or infirmary ought, we contend, always to be. Public institutions, especially those constituted for medical purposes, need to be ruled by men. Women, in so far as they have any place in them, should be content to be servants, and obey. Unfortunately, the honour and excellence of obedience are qualities which women who aspire to even quasi-public positions are slow to appreciate, or wholly fail to perceive.

## Annotations.

"No quid nimis."

## SCURVY.

DR. BUZZARD, in a letter which appeared in our columns last week, considers the fact that the crew of the *Eira* were supplied with *preserved* vegetables tells against the supposition advanced by Mr. Neale, that if Arctic voyagers were to feed only on the flesh of the animals supplied by the country they would be able to dispense with lime-juice. The truth is, it is an open question with many as to the relative antiscorbutic properties of *preserved* vegetables, and whether under the circumstances in which the *Eira's* crew were placed they would have been sufficient, in the absence of lime-juice and fresh meat, to have preserved the crew from scurvy. A case in point is the outbreak that occurred on board the *Adventure*, in the surveying voyages of that vessel and the *Beagle*. The *Adventure* had been anchored in Port Famine for several months, and although "pickles, cranberries, large quantities of wild celery, preserved meats and soups, had been abundantly supplied," still great difficulty had been experienced in obtaining fresh meat, and they were dependent on an intermittent supply from wild-fowl and a few shell-fish. Scurvy appeared early in July, fourteen cases, including the assistant-surgeon, being down with it. At the end of July fresh meat was obtained; at first it seemed to prove ineffectual, but an ample supply being continued, the commander was able to report, by the end of August, "the timely supply of guanaco meat had certainly checked the scurvy." This is an instance in which articles of diet having recognised antiscorbutic properties proved insufficient, in the absence of lime-juice and fresh meat, and under conditions of exceptional hardship, exposure, and depressing influence, to prevent the occurrence of scurvy. So with the *Eira*, we believe that had they not fortunately been able to obtain abundant supplies of fresh meat, scurvy would have appeared, and that the preserved vegetables in the absence of lime-juice would have proved insufficient as antiscorbutics. This antiscorbutic virtue of fresh meat has long been recognised by Arctic explorers, and, strangely, their experience in this respect is quite at variance with ours in Europe. It has been sought to explain the immunity from the disease of the Esquimaux, who live almost exclusively on seal and walrus flesh during the winter months, by maintaining that the protection is derived from the herbage extracted from the stomach of reindeer they may kill. In view, however, of the small proportion of vegetable matter that would be thus obtained for each member of the tribe, and the intermittent nature of the supply, it can hardly be maintained that the antiscorbutic supplied in this way is sufficient unless there are other conditions tending in the same direction. And of these, one, as we have already stated, consists probably in the fact that the flesh is eaten without lactic acid decomposition having taken place, owing either to its being devoured immediately, or from its becoming frozen. The converse being the case in Europe, where meat is hung some time after rigor mortis has passed off, and lactic acid develops to a considerable extent. This seems a rational explanation, and reconciles the discrepancy of opinion that exists between European and Arctic observers with regard to meat as an antiscorbutic. In bringing forward the claims of the flesh of recently killed animals as an antiscorbutic, it must be understood that we fully uphold the doctrine that the exclusive cause of scurvy is due to the insufficient supply of fresh vegetable food, and that it can be only completely cured by their administration; but if the claims advanced with regard to the antiscorbutic qualities of recently slaughtered flesh be proved, then we

have ascertained a fact which ought to be of the greatest practical value with regard to the conduct of exploring expeditions, and every effort should be made to obtain it. Everything, moreover, conducive to the improvement of the sailor's dietary ought to receive serious consideration, and it has therefore seemed to us that the remarks of Mr. Neale and Dr. Lucas are especially worthy of attention, whilst we think the suggestion of the former gentleman with regard to the use of the blood of slaughtered animals likely to prove of special value.

## RARE TRAUMATIC ANEURISMS.

IN the July number of *Gaillard's Medical Journal*, Drs. Fenger and Lee, of Chicago, publish an interesting account of six cases of aneurism, each of which is well worthy of record and study. Two among them are of such rarity that we record their prominent features. A man, aged twenty-eight, received a bullet-wound just below the right orbit, and extending to the outer side of the nasal process of the superior maxilla. This was followed by a good deal of ecchymosis and inflammation, and by great pain on any attempt to open the mouth. After a week the swelling had subsided, but slight tumefaction of the right side of the neck remained. The man now resumed work; but on the fifteenth day after the injury he called on Dr. Lee, complaining of inability to speak or swallow, and of severe pain and stiffness of the right side of the neck. The tonsils and soft palate were so swollen that the back of the pharynx could not be examined. On the hard palate a small firm tumour, about the size of a hickory nut, was felt. Thinking this might be the bullet, Dr. Lee made a small incision over it; this was enlarged, some clotted blood was removed, and then followed a gush of bright arterial blood, which was quickly fatal. At the autopsy, a large cavity filled with old and recent clots was found bounded by the pharynx, the upper cervical vertebrae, and the stylo-hyoid and styloglossus muscles, with a prolongation extending to the swelling on the hard palate. About an inch above the bifurcation of the common carotid artery was a circular opening in the internal carotid vessel, and a second similar one in the opposite wall of the vessel. The bullet was found lying on the adventitia immediately outside this posterior opening. The second case was that of a man, aged nineteen, who received a bullet-wound an inch to the left of the middle line of the back of the neck, on a level with the mastoid process. There was immediately considerable arterial hæmorrhage, which was arrested by bystanders, and then at once swelling about the left angle of the lower jaw occurred, extending upwards and forwards on to the face, and also into the floor of the mouth. The wound was dressed antiseptically. On the ninth day the swelling below the ear pulsated, and there was a distinct aneurismal bruit in it. The left common carotid artery was accordingly ligatured. In a fortnight the patient was well enough to be up all day, the operation wound being almost closed, and the bullet wound quite healed. The man complained of a feeling of pulsation below the left mastoid process, but neither pulsation nor bruit could be detected by examination. Four days later, while undergoing examination in a law court, the man experienced severe pain, and the sensation of pulsation became more intense. The swelling and pulsation increased, and it was evident that the aneurism had recurred. Dr. Fenger determined to operate. An incision was made along the upper half of the anterior border of the sterno-mastoid muscle, and a transverse one from the top of this back through the insertion of the sterno-mastoid. The sac of the aneurism was then opened and the clots turned out, when blood was found to be poured out from the bottom of the cavity, and on further laying bare the parts it

was found to issue from the vertebral artery, where it lay on the arch of the atlas. The vessel, which was here nearly as large as the internal carotid, was tied. While this was being done the respiration and pulse stopped, but under artificial respiration and subcutaneous injections of whisky he man recovered sufficiently to allow the wound to be dressed. Subsequently transfusion of defibrinated blood was performed with marked benefit, and the patient ultimately made a perfect recovery.

#### THE DEFORMATION OF THE BODY DURING SCHOOL LIFE.

AN interesting paper on the above subject was read at the recent Geneva Congress by Dr. Dally. The Swiss Governmental Department of Public Instruction had summoned many members of the teaching body under their jurisdiction to attend the sitting, in order to listen to the various opinions and recommendations on the subject. In his opening remarks, Dr. Dally alluded to the fact that Dr. Chaussier, out of 23,200 newly-born infants examined for this purpose, only found 122 possessing any abnormal peculiarities, and these he counted rather as monstrosities than deformities, being in most cases hare-lips. Thus he argued that a child is straight when it goes to school, and he attributes to the enforced maintenance of one attitude for a length of time the corporeal deformations which are displayed at a later period; the various portions of the juvenile organism are easily displaced, and if the cause continues such displacements become permanent. He further advocated more attention being paid by doctors to the medical aspects of school life. He contested the assertions that muscular action was capable of producing deformations, and that gymnastic exercises could remove them. A point of essential importance, according to Dr. Dally's theory, is the maintenance of the suppleness of the lumbar region, and he condemned the habit of supporting the body on one side only, either in sitting or standing. He remarked that school girls usually stand on their right leg, and attributed this custom (which is to be deprecated) to the fact of their usually inclining towards the left side the weight of the body when sitting down. This last-named position of the body being necessitated in a great degree by the modern system of slanted writing, it was argued by Dr. Dally that a return to a more upright style of penmanship is advisable.

#### A CASE OF CESSPOOL POISONING.

A SINGULAR case of cesspool poisoning has been reported from Lyons by M. Bouveret. Although not altogether unique, it is at least unusual, and is of interest on account both of the symptoms and of an attempt which was made to save the patient by the transfusion of blood. A man, aged twenty-one, was proceeding to empty a cesspool, when he fell into it. He remained in it for a few minutes, at least five, possibly more, and was extracted with difficulty by means of ropes. He was insensible, and all means to restore consciousness being unavailing, he was brought to the hospital a few hours later. His lips were then livid, the conjunctivæ injected, the eyes fixed and turned upwards, the pupils dilated and insensitive to light. Respiration was frequent, sixty per minute; the pulse extremely rapid, but regular and fairly strong. He could not be made to swallow, but from time to time uttered a prolonged cry, and violent tonic spasms occurred in the muscles of the limbs, trunk, and neck, almost as severe as those of tetanus, so that the tongue was bitten. The treatment at first adopted consisted of inhalations of oxygen, which were continued for several hours; but the convulsive attacks continued, and a few hours later the temperature was 103° F. As the patient's condition was extremely critical, transfusion was employed; about 300 grammes of blood were withdrawn from the arm, and

120 grammes of blood obtained from the patient's mother, and defibrinated, were injected. No improvement, however, could be observed. The temperature rose to 104° and the convulsions continued. Death occurred about twenty-four hours after the accident, with a temperature of 105°. At the post-mortem examination the blood was found to be black and fluid. The lungs were extremely congested, and there was bright hyperemia of the bronchial mucous membrane, but no coagulation in the pulmonary artery. Congestion of the kidneys was also present. M. Bouveret, in commenting on the case, regrets that the blood was defibrinated, and that a larger quantity was not injected, thinking that to these two circumstances the inutility of the transfusion may have been due. This proceeding does not appear to have been adopted in any similar case. Sulphide of ammonium is believed to be the chief toxic agent in the contents of cesspools. It is a poison of the blood, acting in the same manner as carbonic oxide, fixing itself on the red globules, from which it drives the oxygen and renders them unable to perform their proper function. In cases of poisoning by carbonic oxide transfusion has been employed with success. Twelve such cases were collected by Casse in 1874, and in six of them the transfusion was successful. Eulenberg and Landois have recommended this proceeding in phosphorus poisoning, and it was employed in one case by Jurgensen, apparently with the result of saving the patient. In poisoning by nitrobenzole it has been employed without result. In many of these cases inhalations of oxygen have proved signally beneficial. Possibly its inutility in the case now recorded was due to the toxic agent. It is probable that cesspools contain gaseous poisons far more complex and more virulent than sulphide of ammonium, and that their action on the organism is at once more profound and less simple.

#### FEEDING LUNATICS.

THERE are few petty operations so difficult as feeding a refractory lunatic. Even with the greatest care and consideration the procedure may do harm. It is no reflection on the management of our asylums to offer the remark that, perhaps, there is too much forcible feeding. If there were more time to spare, and greater personal address on the part of attendants, there would be less need for recourse to the tube. We know men who have had the management of large numbers of violent and obstinate insane folk and yet scarcely ever found occasion to feed by force. It is very much like passing the catheter in hysterical cases. Much may be accomplished by personal influence and the exercise of an authority, which is instantly sacrificed the moment an insane patient comes to look upon his medical attendant as an equal, or even as what is too loosely called a "friend." The necessity for forcible feeding in a lunatic asylum, as elsewhere, is very much a matter of personal discipline, and for the establishment and maintenance of efficient personal discipline more time and care are requisite than can be bestowed on any individual patient treated in a crowd.

#### TRANSFUSION IN THE SEVENTEENTH CENTURY.

A CURIOUS account of the difficulties of a transfusionist of the seventeenth century has been disinterred by the *Union Médicale* from the "Mémoires of Bouteillier d'Ardenay, published in the year 1670. A certain Dr. Denys, of the University of Rheims, who was, moreover, engaged in teaching mathematics in Paris, had a high opinion of the therapeutic value of transfusion; and one day, seeing a young man running naked through the streets in a state of "dementia," tried the remedy upon him with great success. The patient regained his senses and continued well

for two months, but then relapsed into the same dementia. Denys a second time transfused some calf's blood, which he always employed. The patient this time was improved only, and not cured. At the end of a few weeks he lost his senses entirely, and was again brought by his wife to Denys, with the request that he would once more employ his sovereign remedy. Denys hesitated on account of the man's weakness, but yielded to the wife's solicitations. During the operation, as soon as the blood of the animal began to flow through the veins, the patient suffered such insupportable torments that Denys was obliged to desist. The man died six hours afterwards, on which the grateful widow sued Denys for damages for having killed her husband. Denys, however, brought a reciprocal action against the widow on the grounds that she had attempted to poison him. At the trial the judgment went in favour of the widow. Appeal followed appeal, and the case ultimately went up to parliament, where it was pleaded by eminent counsel for the widow and for a Paris surgeon, who was involved in the proceedings on the ground that he had assisted Denys. The latter pleaded his own cause in Latin with great ability. The case seems ultimately to have been discharged, but an edict was issued forbidding the practice of transfusion under pain of corporal punishment.

#### INFECTION AT SEASIDE LODGINGS.

WE are continually receiving cuttings from newspapers and communications of various kinds pointing out—in too many instances very painfully illustrating—the perils of infection which lurk in seaside lodgings to which the weakly or jaded resort for rest and health. There is an irony in the fate which makes these places notorious as centres for the propagation of disease. It is not easy to suggest a remedy, because those who live by letting lodgings regard their visitors as fair game at any risk. If a lodger contracts fever or diphtheria and dies or is removed one week, the bill "to let" will be up again the next week. It has been repeatedly suggested that there should be a systematic registration and inspection of lodgings; but apparently the time has not arrived for the need of such a measure to be publicly felt. Perhaps, when the many cases which are now scattered and therefore overlooked come to be collected and reported *en masse*, public opinion may be stirred in the interests of self-preservation and common sense.

#### FATTY DEGENERATION OF THE LIVER.

THE diagnosis of fatty degeneration of the liver is often extremely difficult—impossible unless the organ is enlarged, and when it is increased in size often doubtful, since the characters of this enlargement are common also to others. MM. Lépine and Eymonnet have drawn attention to a new symptom of the condition, which they believe to be of considerable practical importance. The former, two years ago, called attention to the value of an estimation of the biliary sulphur of the urine as an evidence of the degree of activity of the liver. The indication now pointed out is drawn from the same source. The phosphoric acid of urine, which is in the form of phosphate, is completely removed by treating it with the magnesian solution and baryta water, so that the filtrate contains no trace of phosphoric acid. The liquid is then evaporated, the residue calcined with nitrate of potash, redissolved in water acidulated with nitric acid, and treated with the magnesian solution; a little phosphoric acid will be found, which has evidently been newly formed. This is produced by the destruction, at the moment of calcination, of the phospho-glyceric acid normally contained in the urine, and which forms an integral part of lethicine. In the normal condition the quantity of phosphoric acid thus produced in normal urine is extremely

small, and does not exceed a centigramme—i.e., is not more than the two-hundredth part of the amount of urea contained in the same volume of urine. In several cases of fatty liver the observers have found that the amount, in proportion to the urea, was increased five-fold, or even ten-fold. At present, in no other condition, physiological or pathological, have they met with a similar increase. To what is this fact to be ascribed? Some years ago Dastre and Morat pointed out that the fat of the liver, like many other forms of fat found in the economy, contains lethicine. Lépine and Eymonnet have verified this statement by the direct analysis of livers which were in a state of fatty degeneration, and they have found, moreover, that the amount of lethicine under these circumstances is very large, amounting to no less than 3 per cent. of the fresh organ and 15 per cent. of the dried tissue.

#### THE INFLUENCE OF ALTITUDE ON HEALTH.

THIS subject (which was one of special local interest) was treated at some length at the Geneva Congress by the president, Dr. Lombard. He attached particular importance to the hygienic advantages to be derived from moderate altitudes of, say, 1500 to 3000 feet, in contradistinction to the effects produced by the more lofty portions of the mountainous regions of Switzerland and other countries. He dwelt on the advantages of the Engadine as a residence for persons of consumptive tendencies, and also described some of the sanatoria in the Himalaya Mountains. M. Paul Bert, while agreeing with the general principles laid down by Dr. Lombard, contributed some interesting details as to experiments he had made in his own person (in conjunction with several scientific friends) with a view to proving the efficacy of the inhalation of oxygen as a restorative process in cases where the excessive rarefaction of the atmosphere at extreme altitudes produces a kind of asphyxia. The general tendency of M. Bert's theory is to supply the oxygen which is wanting in the air at such heights, and the experiments he and his friends made consisted of the production, by artificial means, of this "mountain-sickness," and its removal by the inhalation of air with a full proportion of oxygen. The subsequent experiences of aeronauts tend also to prove that the inhalation of oxygen is an immediate remedy for the quickening of the pulse and of the respiration, the headache, somnolence, and partial loss of reason, which are amongst the symptoms of the injurious effects of extreme altitudes.

#### THE INFLUENCE OF BLOOD PRESSURE UPON CARDIO-INHIBITION.

MESSRS. SEWELL and DONALDSON, assistants of Professor H. Newell Martin, have been investigating the effect of alterations of blood pressure within the cavities of the heart upon the inhibitory function of the pneumogastric nerve. Their mode of experimenting and the results obtained are set forth in a paper published in the current volume of the "Transactions of the Medical and Chirurgical Faculty of the State of Maryland." The animals mostly employed were the frog and terrapin. The animal was beheaded and pithed, one cannula inserted into the inferior cava, and one into the innominate artery or one of its larger branches, and all the other vessels leading to and from the heart were tied. Defibrinated blood flowed into the venous cannula under constant pressure, which could be raised and lowered at will; the arterial pressure could be measured and varied in a similar manner. Both vagi were prepared for electric stimulation. With increase of the venous pressure while the arterial pressure remained constant, it was found that the inhibitory effect of an electric stimulus was lessened. Thus with a venous pressure of 2 cm. the heart's beats at

5.4 per 10 secs. were reduced by stimulation of the vagus to 3 in 10 secs.; when the venous pressure was raised to 8 cm. the same electric current had no effect in slowing the heart. On the other hand, variations of the arterial pressure were found not to have any effect upon the action of the vagus. Again, increased pressure upon the interior of the ventricle during diastole, which was necessarily associated with increased resistance to the auricular systole, had no influence upon the vagus action; but if blood found its way back into the auricles during their diastole, then the effect noted above was obtained. Subsequent experiments showed that the effect was the same whether the increased pressure was brought to bear upon the auricles or the sinus venosus during diastole. Many experiments were made on dogs to ascertain whether the effects were the same in the mammal, but owing to special difficulties in carrying out such investigations in warm-blooded animals, no satisfactory results have yet been obtained. But so far as could be ascertained, it seemed that increased venous pressure causes in the mammal also a lessening of the cardio-inhibitory action of the vagus.

### BRISTOL GENERAL HOSPITAL.

AT the half-yearly general meeting of the Board of Subscribers to the General Hospital of Bristol, held last week, the President (Mr. Proctor Baker) related the circumstances under which the committee had felt compelled to authorise extensive and costly alterations to be made. Early in the summer unpleasant smells were noticed in the hospital, and a little later on an outbreak of diarrhoea occurred among the in-patients. Mr. Eassie was requested to report upon the sanitary condition of the building, and he found that not only was the ventilation of the wards imperfect, but that the drains which were connected with the main sewer were not ventilated and were clogged with foul matter, and that the arrangements were altogether so imperfect that there was a constant escape of sewer-gas into the hospital. He also reported that the only satisfactory way of dealing with the evils was to make an entire and radical alteration in the system of drainage. The medical officer of health and the city engineer were also consulted, and could only concur in the advice tendered by Mr. Eassie. It was then suggested that the closure of the hospital for these repairs was a suitable opportunity for re-laying the floors, the cement having proved so unsatisfactory; and the wooden floor which was laid experimentally having been found to be far superior, it was accordingly recommended that the whole hospital should be re-floored with wood. The committee wisely determined to sanction both of these schemes, which are estimated to cost nearly £7000, but which are necessary to make the hospital worthy of the time and of the city of Bristol. We congratulate the committee on its courageous determination that nothing shall be lacking on their part to ensure attainment of the object of the great institution under their management, and we are confident that the citizens of Bristol will shew their appreciation of such honourable and enlightened conduct by supplying the authorities with the necessary funds.

### THE TREATMENT OF POLYDACTYLISM.

ONE or more supernumerary digits, or polydactylism, is one of the most frequent of congenital deformities. It presents, however, considerable variety in its nature. In some cases there is only a mere rudiment of a finger or toe consisting of skin and fibro-cellular tissue with usually a small piece of cartilage in the centre, adherent to one of the fingers, and more common on the inner than the outer side of the hand. In other cases the digit is perfectly formed and articulates either with the shaft of a phalanx or a metacarpal bone of another digit, some-

times in common with the normal finger, with a broad head of a metacarpal bone, or in still rarer instances upon one extremity of a bifurcated metacarpal or metatarsal bone. Cases are also met with in which the additional finger or toe has been united along its whole length with the next digit—a combination of polydactylism and webbed finger. Where the digit is a mere rudiment, it is always an unsightly and useless appendage, and should be removed at quite an early age by division of the pedicle with the ligature, knife, or, as recommended by M. Polaillon, the galvanic cautery. Where, however, the digit is fully formed and supplied with muscles so that it shares in the movements of its fellows, it becomes a question whether it should be removed, the answer to which depends upon the utility of the supernumerary digit and the extent of the deformity occasioned by it. The removal of these digits is a perfectly simple operation; but when they articulate with a metacarpal bone within the same capsule as the normal digit, there is a danger of exciting inflammation in this joint, and of so causing ankylosis. To obviate this M. Sédillot advised that in such cases the amputation should be made through the base of the digit to be removed so as to leave the articulation intact. This plan has been generally adopted of late years, but there seem to be reasons for modifying Sédillot's advice. In the first place, we are now enabled to open healthy joints without exciting inflammation or running the risk of ankylosis. And in at least three cases the base of the digit left behind has subsequently grown, and in part reproduced the deformity. M. Chréten, to whom such a case has recently occurred, has suggested that the explanation of this is that the base of the phalanx is ossified from a separate epiphyseal centre, and that when the amputation is so performed as to leave the epiphysis unimpaired it may continue its independent development. In the rare cases of a bifid metacarpal bone the amputation should be made at the point where the shaft of the bone bifurcates. There is, of course, less reason for undertaking any of these operations in the foot than in the hand.

### CERTIFICATION OF DEATH IN DOUBTFUL CASES.

THE *Bristol Daily Mercury* reports an inquest on the body of a young woman, Elizabeth Hemfield, at Hallowtree Inn, Hallowtree, who a few weeks before had been a patient at Newport Infirmary, under the care of the house-surgeon. No medical man saw her at Hallowtree, and the accounts of her last illness, as reported, are too meagre to base any opinion on. Mr. Perrin was called, but found the patient dead. The house-surgeon of Newport Infirmary under these circumstances was applied to, and reluctantly gave a certificate of death from consumption, of which at some period she had presented symptoms. It should also be stated that this gentleman (Mr. R. H. Dowse, M.B.) said at the inquest that two and a half years since he had removed a polypus from the uterus. Other evidence, however, was imported, not of a convincing but of a suspicious character, pointing to miscarriage, if not to the production of abortion by unfair means. The deceased herself had said that she had undergone an operation about a week before coming to Hallowtree; the appearances of the breasts were suspicious, as well as of the sheets showing great hæmorrhage. A post-mortem examination by Mr. Perrin confirmed these suspicions. Under these circumstances, after deliberating a few minutes, the jury returned a verdict of death from hæmorrhage after miscarriage, but that there was no evidence by what means it was caused. They added an expression of opinion that doctors should be more careful in giving certificates.—“The coroner: Do you mean doctors in general, or Dr. Dowse?—The foreman: Doctors in general.” Juries, however, should confine themselves to the facts of the particular case under consideration. We do not think that doctors often give certificates in this

way, and Mr. Dowse only did so in this case on the representation of friends that an inquest might be prevented by his doing so. The case, however, should serve as a caution in such matters.

### TUBERCULOSIS OF THE TONGUE.

DR. THOMAYER, of Prague, describes three cases of tubercular ulceration of the tongue. In one a wide fissure existed about the middle of the dorsum, with yellow-coated base, and prominent coarse tubercular nodules at its margins. In both lungs there was widespread tubercular disease. In the second case the ulcer occupied the right half of the tip of the organ, and was characterised by numerous firm granulations in part of its base, the rest being covered by a thick yellow layer; the margins of the ulcer were also firm, beset with grey and yellow granulations. The ulcer bled slightly, and was not benefited by treatment. The third case was similar, only the ulcer was seated on the frænum. It was treated by the topical application of chloride of zinc, which produced only temporary benefit in the breaking down of the nodules. Microscopical examination was made of the diseased organ in the two fatal cases. The ulceration had destroyed the mucous membrane and submucous tissue, and the base was formed by a thick layer of small round cells, intersected here and there by muscular bundles. Beneath this layer, there spread into the intermuscular spaces masses of similar cells, which, under high powers, were found to consist partly of giant-cells, and to be separated by the delicate stroma of tubercle. Some isolated tubercles were found deep in the substance of the organ. The muscular fibres themselves seemed invaded by the cell-growth, which was not limited to the intermuscular spaces. There was proliferation of muscle nuclei and of endothelium of the blood-vessels. Dr. Thomayer says that the extent of the lesion demonstrates the futility of treating these ulcers by caustics, and points to the advisability of excision.

### THE DISSEMINATION OF SCARLET FEVER.

IN his second recently delivered Ingleby Lecture on Scarlatina, published in the current number of the *Birmingham Medical Review*, Dr. R. C. R. Jordan makes the following remarks upon the mode of dissemination of the disease, which put the facts in a concise form. He says:—"Of the means by which the infection of scarlet fever is spread little is known with certainty; there is no proof that it can be disseminated through water, or by milk-walks, except by the agency of the milkman or his clothes, as in the case of typhoid fever; no evidence that the dejections can contaminate wells, or that the poison can be conveyed by drainage; there is no proof that it can be taken into the stomach by the agency of food or drink. The popular fallacy of its being carried by the desquamating epidermic scales has no evidence in its favour. There is a strong probability, amounting almost to certainty, that it can be taken in by the breath, and probably from the breath where there is sore-throat, long before the period of desquamation. Surgical cases in the vicinity of the epidemic give every proof that it can be absorbed by wounds or raw surfaces, as in direct inoculation, though this last process seems not to be often effectual when intentionally tried. Surgical scarlet fever is, curiously, almost always mild in character. The tendency to infection seems equally strong in puerperal cases, where the disease, on the contrary, generally assumes a very malignant type. The virus can plainly be carried by means of clothes, or even by less probable agents, as books or papers. There is every proof short of absolute demonstration that it may be conveyed by a laundress, from the mingling of healthy with infected clothes; it can contaminate cabs or railway carriages; and it has a great power of inherent vitality."

### ALCOHOLISM IN RUSSIA AND IN ENGLAND.

WHATEVER there may be inconvenient or objectionable in the rivalry between Russia and England, there is one movement in both countries in which rivalry cannot be too keen—namely, one to abate the amount of drunkenness. On this subject we would strongly commend to the attention of our readers an article in the September number of the *Nineteenth Century*, by Olga Novikoff, née Kiréef. This Russian writer quotes figures from the *Journal de St. Petersburg*, showing the annual consumption per head in litres in Russia, England, and Germany:—

	Alcohol.	Beer.
Russia .....	10 .....	27, $\frac{1}{2}$
Germany .....	3 $\frac{1}{2}$ .....	88
England .....	5 $\frac{1}{2}$ .....	143

He thinks these figures hardly justify the complacency with which England is apt to denounce Russian intemperance. He says that Russian peasants spend 10s. each, on an average, in strong drink, the English £4. In Great Britain thirty-two millions of people spend £136,000,000 annually. In Russia ninety millions spend about £50,000,000. It is gratifying to know that the Government, the Greek Church, and the people themselves, through their communal institutions, are all alive to the national degradation and disgrace caused by drink, and are all engaged in attempts to increase national and individual temperance. The Government of the present Emperor has especially distinguished itself in this way. It took the initiative in opposing the "traditional custom (drinking) of the sage and laborious portion of the population on holy days and family solemnities." It appointed a commission of experts, selected from the zemstvos of the empire for their special acquaintance with the subject to be discussed. As in this country, the question of national revenue painfully checks the proper consideration of this question. But it is clear that English statesmen will have to face it in its moral aspects as well as in its financial ones if they are not to be outdone by Russian statesmen. The chief recommendations of the Commission are:—1. Liberty to communes to close all places for the sale of drink. 2. Permission to communes to establish communal monopolies of the sale of drink. 3. No public-houses to be established above 25 per cent. in excess of one per thousand of the population. 4. Tea and food to be sold at all places where drink is consumed on the premises. 6. Rigorous supervision of public-houses by local authorities. We cannot give more space for a notice of this article, which, in spite of a little satire, not to say ill-nature, is a most interesting one.

### A CASE OF HERMAPHRODITISM.

ON Monday last one of the patients in the British Lying-in Hospital was delivered of a living child, which upon examination was found to present the characteristics of so-called spurious hermaphroditism. When the child was seen two days after birth the condition of the external genitals was found to be as follows:—There is a large penis or clitoris, with a prepuce bound down by a strong frænum. Immediately below this is a small canal capable of admitting a good-sized probe, and from which urine is voided. The penis (?) is of natural size for a newly-born infant, and presents at the apex a well-marked depression, resembling the external urinary meatus. The scrotum (?) is divided, and resembles the female labia, but no trace of testes can anywhere be discovered. So equivocal are the appearances that it is at present impossible to determine the sex of the child. Dr. Fancourt Barnes, whose patient the mother is, seems to incline to the opinion that the type is rather feminine than masculine. If the child live, it will in all probability be shown to the members of the Obstetrical Society, when the problem of the sex may be solved.

### THE PROFESSION OF LIVERPOOL AND INFECTIOUS DISEASES.

A COMMITTEE of the medical profession of Liverpool and its neighbourhood has been held. It suggests, in place of a bare notification of infectious disease, which it thinks would be valueless, a local Bill, including the following powers:—

1. To obtain from every dispensary and district medical officer early notification of cases of infectious disease, in the same manner as is now done from recently appointed medical officers of district schools and parochial medical officers, a fee of 2s. 6d. being paid for each certificate so forwarded.
2. To give to every other medical man the option of making early notification on similar terms.
3. To make Section 90 of the Public Health Act applicable to Liverpool, a proceeding which would impose the duty of early notification of the tenants-in-chief of every sublet house in the city below a certain rental, and which would give the sanitary authority the power, which they do not now possess, of compulsory removal to hospital in cases which should seem to require it.
4. To demand that School Board authorities shall require from every child who shall have been more than two days absent from school a certificate to the effect that neither he nor any member of the family with which he resides is affected by an infectious disease.
5. To appoint special medical inspectors of dairies under the Contagious Diseases (Animals) Act.
6. To obtain a place of refuge or quarantine, in which, in case the closure of dwelling-houses should be deemed necessary in consequence of infectious disease, the uninfected inmates might be temporarily lodged.
7. To hire nurses for attendance on those suffering from infectious disease who should be retained in their own house.
8. That early application should be made to the Local Government Board for the right to make house-to-house visitation, to provide for the speedy interment of the dead, &c., on the outbreak of any epidemic disease.

We cannot say that these suggestions, said to have been adopted by the profession in Liverpool, supersede, in our judgment, the necessity for a system of compulsory notification by the householder. Under such a Bill notification by the doctor is optional, and he is to get a fee for it. Would this place the profession in a dignified or convenient position? The other powers are a part of a great system of public medicine, which we cannot discuss now. One of these, however, we may say, will give great trouble to medical men—a medical certificate from every child who has been two days absent from a Board School. It seems to us that the profession in Liverpool would do well to give their help to a system of notification by the householder. This would be an educating piece of legislation, and one that would afford a basis for more elaborate requirements, such as are specified in their report.

### THE ALLEGED INCREASE OF LUNACY.

THE appearance of the annual report of the Commissioners in Lunacy is, as usual, being made the occasion for a revival of the outcry for further "asylum accommodation." This is particularly unreasonable in the year of grace 1882, because, taking the worst possible view of the matter, the increase of January, 1882, upon January, 1881, is actually *less* than that of January, 1881, upon 1880. The increase, such as it is, exists almost exclusively—this year wholly—in the class of paupers; and while the pauper patients returned for the 1st of January, 1881, numbered 1801 more than the total returned for January, 1880, the pauper patients counted on the 1st of January, 1882, numbered only 1717 more than the total returned for January 1st, 1881. Assuming these figures to be correct—we are dealing with them at second-hand—it is difficult to find anything to justify the alarm which appears to have been excited in certain quarters. The truth is, there is no solid reason to suppose lunacy is increasing at a greater rate than the population increases. What seems to be in-

crease in the asylum populations is really accumulation, caused by the wholesale certifying of "lunatics," and increased longevity due to the improved care and treatment of the inmates of asylums, and therefore creditable to our philanthropy.

### HYALINE DEGENERATION.

IN the last number of Virchow's *Archiv*, Dr. Max Vallat describes in detail the process of hyaline or fibrinous degeneration of tubercular formations—a change which has only received full attention of late years, although it is not infrequent in other structures, especially in the walls of arteries. In tubercles, it is best observed in those which occur in the spleen, lymphatic glands, and liver, and is to be regarded as an early stage of caseous degeneration. Dr. Vallat concludes that it is formed from the reticulum of the peripheral zone of the tubercles, and also from the trabecular tissue of the spleen and lymphatic glands, the bands becoming thickened, homogeneous, and glistening, whilst the spaces between the original fibres become converted into narrow channels in which only the nuclei of the cells that formerly existed there remain. In the tubercle it also replaces the epithelioid and giant cells, the former appearing to be converted into homogeneous non-nucleated masses. The precise share taken by the giant cells in the formation is unknown. The channels left between the degenerated and swollen bands allow of the passage of fluid and pigment particles into the interior of the tubercle. In caseating the material breaks up into a finely granular mass, and is often found to be beset with nuclei, either the relics of previously existing cells or immigrants from surrounding vessels.

### PROPOSED INTERNATIONAL HYGIENIC CONVENTION.

A PAPER read at the Geneva Congress by Dr. L. de Csatory (member of the Hungarian General Council of Public Hygiene) recommends the organisation of the above-named convention for the purpose of securing uniformity in national legislation affecting the public health. It is suggested that an international committee of surveillance should be established in order to secure the due observance of such hygienic measures as might be adopted in common by the various nations thus leagued together. A committee was appointed to prepare the scheme in detail for presentation to the next Congress at the Hague, prior to communications being officially made to the authorities of the several countries interested.

### DR. KLEIN ON VACCIN CHARBONNEUX.

FROM the subjoined report it will be seen that Dr. Klein has arrived at conclusions—based upon comparatively few experiments, it is true—adverse to the general adoption in this country of Pasteur's proposal to inoculate cattle with anthrax as a prophylactic measure against that disastrous disease. The report has been communicated to the Veterinary Department of the Privy Council by the Local Government Board, and is published in the current number of the *Veterinarian*:—

"Vaccin charbonneux is to be obtained, and is announced to be obtainable (in the *Farmer*), from M. Bontroux, agent of M. Pasteur in Paris (applicants to M. Pasteur are referred to M. Bontroux), and, as I happen to know, it is brought over and sold and used in considerable quantities. The 'vaccin' is sold in tubes (each containing enough lymph for the inoculation of 100 sheep or fifty cattle) as 'premier vaccin charbonneux' and as 'deuxième vaccin charbonneux.' The 'premier vaccin,' according to the printed directions accompanying each lot, is inoculated first; after a lapse of twelve to fifteen days the 'deuxième vaccin' is used in the same manner. The animals thus twice inoculated are

supposed to be immune against fatal anthrax. I have obtained through two independent sources two lots of this vaccin charbonneux (premier and deuxième), and have tested them by experiments. The results of these experiments enable me to say—(a) animals inoculated with this 'vaccin' (premier and deuxième) are not made immune against fatal anthrax; and (b) both the first and second vaccin may produce fatal anthrax. The following facts prove these propositions:—

"Experiments with Lot A.—Inoculated with 'premier vaccin,' two sheep, two guinea-pigs and two mice; no change in any animal. Inoculated with 'deuxième vaccin,' the two above sheep and the two above guinea-pigs. One of these sheep showed rise of temperature, and falling off in food for the first two days after this second inoculation, but was all right again after three days. The two guinea-pigs were dead of typical anthrax within forty-eight hours. The above mice were inoculated with the blood of one of these guinea-pigs. Both mice were dead of typical anthrax within forty-eight hours. The two sheep having been inoculated with the premier and deuxième vaccin ought to have been immune against fatal anthrax. Now see what happened: according to M. Pasteur, the *Bacillus anthracis* of blood of an animal dead of anthrax, when cultivated at 42°–43° C. for twelve days, loses all virulence and becomes thereby converted into 'vaccin.' I had grown the *Bacillus anthracis* of blood of a guinea-pig dead of anthrax at a temperature of 42°–43° C. for twenty-one days, and with this culture I inoculated the above two sheep. The result was that both animals were dead of typical anthrax within forty-eight hours.

"Experiments with Lot B.—Inoculated with 'premier vaccin' four guinea-pigs and six mice. Within forty-eight hours three of the guinea-pigs and three of the mice were dead of typical anthrax. My method of using the fluids for inoculation absolutely precludes any accidental contamination, and hence these must be accepted as perfectly reliable. This country is comparatively free from anthrax, and therefore the introduction and use of this so-called 'vaccin charbonneux' seems to me most dangerous, and capable of producing incalculable mischief."

#### THE LATE SURGEON-MAJOR GEORGE SHAW, A.M.D.

VERY great regret is everywhere expressed at the sad death in action at Kassassin Lock of Surgeon-Major Shaw. He had previously served with credit and great devotion in the Afghan campaign, and accompanied the advance of the first field hospital through the Khyber Pass in December, 1878. He was beloved by all who knew him, and endeared himself to the men of the régiments with which he served by his gentleness, his sympathy, and his devoted interest in his work. Every officer and man of the medical service of the army who knew him mourns for one of the most amiable of men who ever served in the army.

#### TYPHOID IN GOVANHILL.

ANOTHER typhoid fever epidemic, fortunately of rather more limited dimensions than is usual, and pretty clearly traceable to the insanitary condition of a farm supplying the neighbourhood with milk, is reported in the southern districts of Glasgow, namely in Govanhill and part of Crosshill. In all the cases noted the families affected had been getting their milk from dairies supplied by the farm in question. When the farm was inspected, it was found that a common open drain, commencing at the dunghill, ran behind the byres, and within less than a yard of the drain a circular well was situated, the bottom of the well and the drain being almost on a level. The drain was a capacious one. It was supplemented by the smaller drains from the byres and scullery, and was filled with fluid and sewage matter,

so that percolation from the drain to the well was very probable. The well was used for household requirements, and for washing the dairy utensils. A case of fever had occurred in the house, but was stated to have been rheumatic fever. Unfortunately, the authorities of the districts in which the epidemic occurred have no power to interfere further than to communicate the facts to the local authority of the country district in which the farm is situated, and, failing attention, the Board of Supervision might be approached. The powerlessness of large city populations in such circumstances is not very reassuring.

#### THE ASYLUM SYSTEM.

THE following significant passage appears in the twenty-fourth Report of the Commissioners in Lunacy for Scotland: "Dr. Fraser is of opinion that there is an increasing tendency at present both to resort unnecessarily to asylum treatment, and also to detain patients longer than is proper after asylum treatment has been resorted to. 'In proof of the first averment,' he says, 'the reports of many of our medical superintendents of asylums can be put in evidence; for in them are contained complaints of having to admit patients who in their opinion could have been sufficiently cared for in a private dwelling or at home. Many rural inspectors of poor seem to regard the asylums not only as a place for the treatment of the insane, but also as a hospital for the treatment of any form of nervous disease with which mental enfeeblement may be associated, or as a home for aged persons whose faculties are failing; and relatives now prefer the asylum for their paralytic friends to the poorhouse, as the former implies a more dignified form of pauperism than the latter. The question suggests itself to me—has not the misuse of asylums now set in? and I feel forced to reply that I perceive what seems to me unmistakable evidence of a too-ready inclination to resort to them as the only provision for all who suffer under any form of mental unsoundness.'" We believe this to be a perfectly just statement of the plain facts as regards the abuse of asylums in England, as well as Scotland. In presence of the pressure which is everywhere being brought to bear on justices and ratepayers to increase asylum accommodation, it would be well to lay this official testimony to heart.

#### THE PARKES MUSEUM.

HIS Royal Highness the Duke of Albany has consented to become the President of this Museum, which has recently been incorporated and is now in course of removal to new premises in Margaret-street, W. This is a new proof of the interest which His Royal Highness takes in all questions which affect the public welfare, and we trust that the Museum, under the auspices of its Royal President, will continue the successful career of usefulness which it so well deserves.

#### FERRUGINOUS LIVERS.

THE presence of an excess of iron in the livers of anæmic patients is a curious fact, of which several instances have been described in Germany. One case was described by Stahl; and Lindenlang, in the liver of a patient with purpura, found a considerable excess of iron. Marchand has lately described the liver of a phthisical patient, aged sixty years, which presented an unusual brownish-red colour associated with evident cirrhosis. The microscope showed an infiltration of the hepatic cells and of the interstitial connective tissue by pigmentary corpuscles, which gave the characteristic test for iron with yellow ferrocyanide. A chemical analysis showed that the ashes contained not less than 30 per cent. of iron. It has been supposed that the excess of iron is the result of an abnormal destruction of red

blood-corpuscles in the organ, but it is open to question whether it is more than the result of the free administration of iron by the mouth.

#### A BASELESS CHARGE.

THE unfounded charge brought against Mr. Arnold, of Bishop Auckland, Licentiate in Midwifery of the Durham University, in the local police court a few days ago, affords another illustration of the importance of securing the presence of a female friend of the patient in cases where a woman has to undergo an examination by a surgeon. The accusation proved to have been of the most baseless kind, and yet it was one which hysterical patients are apt in similar circumstances to prefer in all good faith, unless reassured by the presence of a third person. We congratulate Mr. Arnold on the unequivocal decision of the chairman of the court, and sympathise with him in the annoyance to which the absurd charge must have subjected him.

#### TRICHINÆ IN ADIPOSE TISSUE.

IT has been generally assumed that trichinæ occur only in the muscular substance, and are not found in the fatty tissue. Chatin's latest investigations have, however, shown that trichinæ occur uniformly in the latter, where the parasites are free or only loosely connected with the neighbouring tissue elements. Their nature may readily be mistaken, but is shown by the simultaneous occurrence of encapsuled trichinæ in the muscular tissue. Experiments proved that animals fed with trichinous fat exhibited no indications of trichinosis, while others fed with the flesh from the same infected animal quickly suffered and died with symptoms of intestinal trichinosis; although further observations on the comparative innocuity of the fat must be made before the fact can be regarded as of hygienic importance. The practical value of the discovery at present seems to be that the fat, as well as the flesh, of suspected animals should be examined.

#### SALE OF DISPENSARY LETTERS BY PUBLICANS.

ONE remarkable incident at a late inquest was a statement with reference to the medical letter which the deceased's wife said she had tried to get at a neighbouring publichouse, and which was to be had for threepence. The coroner said he had been informed the letters in question were purchased for distribution by the landlord. It is not entirely new to us. We have heard before of subscriptions to a benevolent institution being used in a similar sort of way by publicans and other tradesmen. They are not exactly sold, but given to customers. Such a use of dispensary or hospital letters should be declared illegal.

#### MEDICAL AID ASSOCIATIONS.

WE have never withheld our disapproval of wholesale combinations of friendly societies with the view of getting medical attendance for members and their families on terms altogether inadequate. We are neither sorry nor surprised, therefore, to see that such an association at Chesterfield—the Chesterfield Medical Aid Association—is to be wound up for want of funds. It is unworthy of provident societies to try to reduce the remuneration of medical men.

THE latest advices from South Africa represent the epidemic of small-pox at Cape Town as increasing. The outbreak is causing much consternation, and energetic measures are being adopted in the neighbouring towns to prevent the importation of the disease. Vaccination, it appears, is being vigorously carried out.

AT a Quarterly Court of the president and managers of the Aberdeen Royal Infirmary, held on the 11th inst., the question of the extension and improvement of the building again came up for discussion, in connexion more especially with the proposition to erect a ward or wards for the treatment of diseases of the chest. Professor Stephenson suggested a widening of the basis of the proposition, and moved the following resolution, which was unanimously agreed to:—"That, in addition to the question regarding a ward for diseases of the chest, it be remitted to the committee of management to consider and report upon what additional accommodation and improvements are required in the present buildings, and what special wards, if any, are necessary to render the services of the institution more efficient to the public."

WE regret to announce the death from apoplexy of Dr. Waller Lewis, for more than a quarter of a century medical officer at the General Post Office. Dr. Lewis died from apoplexy on the 7th inst., at Whitby, where he had been staying for some days with his wife and two daughters. The reports by him on the State of the Burial Vaults of the Metropolitan Churches, on the Origin and Spread of Epidemic Cholera, and on the Laws in force in France for regulating Noxious Trades, were regarded as of sufficient importance to be presented to Parliament.

THREE lives were lost last week by the falling of a portion of St. Patrick's Cathedral, Dublin, which was undergoing repairs. One of the deceased, a nursery maid, was admitted into the Adelaide Hospital, but succumbed a few minutes afterwards. Her injuries were frightful, and consisted of a fracture of the skull and of the vertebral column, of both femora, and of the right leg close to the ankle. She was buried in the débris with the child in her arms, the latter having escaped with only a lacerated wound over one eye and some bruises.

A VACANCY has occurred in the medical staff of the Dorset County Hospital through the resignation of Mr. J. Good, one of the honorary surgeons. Mr. Good's connexion with the institution extends over about forty years. He was one of the house-surgeons appointed when the hospital was first established, and for the last fifteen years he has officiated as an honorary surgeon. The candidates who have already come forward to fill the vacancy are Mr. E. Good, Mr. J. A. George, and Mr. F. B. Fisher.

SOME time ago a few gentlemen subscribed a sufficient sum to purchase and equip a carriage ambulance for use in Greenock. A few days ago a meeting of subscribers was held, and a committee was empowered to buy one of Howard's ambulances, costing about 100 guineas. The carriage is to be furnished with splints and all necessary apparatus. This is a kind of conveyance much needed in Greenock.

MR. MITCHELL HENRY, M.P., *The Times* states, had the honour of entertaining the Lord Lieutenant of Ireland at his fine seat, Kylemore Castle, Galway, where his Excellency was most hospitably entertained by Mr. Henry, who, as our readers will remember, was formerly surgeon to the Middlesex Hospital.

BY the death of Dr. Waller Lewis the appointment of Chief Medical Officer to the General Post Office has become vacant. The salary is £1000 per annum. Mr. George Carrick Steet, F.R.C.S. (exam.), the second medical officer, will probably succeed Dr. Lewis.

THE outbreak of typhoid at Bangor, though the cases are gradually assuming a milder type, cannot, in point of number of fresh attacks, be said to be on the wane. Forty cases have been reported since Sunday last. The tent hospitals are full, and other means provided of treating the patients are taxed to the utmost extent; whilst the schools remain closed.

THE municipality of Turin lately opened a competition for the best treatise on hygienic science as applied to the requirements of rural districts. The prize has been awarded by the jury charged with the decision to Dr. Layet, professor of hygiene at Bordeaux. It consists of a sum equal to about £100.

THE occurrence of small-pox at Faversham, although not at present of alarming proportions, has led to the resumption of negotiations between the rural and urban sanitary authorities of the town with the view to the erection of a hospital for cases of infectious disease.

THE cholera epidemic at Manilla is declining. An official telegram, dated Sept. 19th, gives the number of deaths on the day previous as 33, 121 having occurred in the vicinity of the town. On the 12th inst. the numbers were respectively 94 and 164.

THE examinations for certificates in Sanitary Science of the University of Cambridge begin on Tuesday, October 3rd. Candidates must send in their names to Professor Liveing, Cambridge, on or before September 28th.

WE regret to hear that Surgeon-Major Hogg has been suffering from cardiac dropsy for the past two months, and is lying in a precarious condition at Morar.

THE annual address at the Medical Society of University College will be delivered by Professor Lister, F.R.S., in the Botanical Theatre, on Oct. 11th, at 8 P.M.

IN consequence of the prevalence of scarlet fever in Chelsea, a house-to-house visitation in various parts of the parish has been made by direction of the medical officer of health.

## Public Health and Poor Law.

### LOCAL GOVERNMENT DEPARTMENT.

#### REPORTS OF INSPECTORS TO THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

THE following reports on outbreaks of diphtheria have recently been submitted to the Local Government Board:—

*King's Lynn.*—Dr. Airy's report deals with an outbreak of diphtheria in King's Lynn during the latter part of 1881 and the early portion of the present year. The town, which has some 19,000 inhabitants, is described as lying on flat alluvial ground on the eastern bank of the Norfolk Ouse at the head of the New Cut, an artificial channel some four miles in length, which discharges into the Wash and gives access to the port of Lynn; it is also intersected by several creeks communicating with the river and admitting tidal water. The water-supply is derived from springs rising from the lower edge of the chalk formation; it is liable to some contamination, but, owing to the strength of the springs, this is perhaps inconsiderable. The ventilation of the sewers is insufficient and also defective in so far as it is carried out

by rain-water pipes which opening out under projecting eaves and near windows are liable to convey foul air into dwellings. The privy accommodation is in many instances thoroughly bad, a so-called decomposing cistern, which is nothing but a cesspool, intervening between the closet and the sewers. The early cases of diphtheria consisted of slight and severe sore-throat, with cases of so-called follicular tonsillitis and diphtheritic sore-throat, scattered about in different parts of the town, with rarely any probable clue of personal infection. The outbreak is described throughout as being characterised by a comparative absence of those conditions of personal transfer so usually associated with epidemic prevalences of diphtheria; indeed, out of sixty well-marked cases of the disease in thirty-nine households, the attacks in eleven households only could possibly have been due to school assemblage; only three were believed to have been due to domestic intercourse, thus leaving twenty-five cases of household invasion without any known circumstances of personal communication by which they could be explained. Having regard to this fact, Dr. Airy examines in much detail all the possible sources of the disease. The water-supply, the means of drainage, the system of excrement disposal, are all considered in this connexion, and, though faulty, they do not singly or together suffice to explain the distribution of the infection. Milk was not at fault; the prevalence of epizootic disease and other occurrences also fail to afford an explanation. The question of damp, with the special fungoid growth attendant upon it, to which diphtheria has often been attributed, is not dealt with; and though many of the houses affected exhibited these special conditions, yet dampness is too common a condition in Lynn, with its foggy air and many creeks, to account for an occasional outbreak. It is interesting to note that some of the mould and fungic mycelium found in houses where sore-throat prevailed was carefully examined by a skilled mycologist, Mr. C. B. Plowright, medical officer of health for an adjoining district, and the exact nature of the cryptogamic growths was identified. But none of these conditions afforded any solution of the difficulty in which Dr. Airy found himself placed as regards the cause of the disease, and he finds himself almost involuntarily thrown back upon the supposition of an atmospheric infection. The report describes how there had recently been a digging out of the mud of the ancient river-bed and of a creek which had been a sewer to the north of the town, and Dr. Airy proceeds to inquire whether this process can have liberated into the air long-buried germs of indigenous diphtheria, causing microzymes possessing a vitality and endurance and power of survival similar to that possessed by the organism which causes malaria, a disease which had formerly prevailed in this very locality. The discussion of this is very exhaustive, and it certainly appears that if any infection of the air did thus result which could have brought about diphtheria, the conditions and direction of the wind-currents corresponded in a remarkable manner with those occurrences, certain districts being affected by the disease a few days after the prevalence of a wind favouring the conveyance of infection from the works to the localities in question. Several groups of cases do not admit of any such explanation; but when once a poison like diphtheria is scattered about a town having faulty sanitary arrangements such as obtain in Lynn, and possessing many channels by which personal infection could operate, it must be admitted that the distribution of a specifically poisonous matter such as is associated with diphtheria by more than one channel is more than probable. On the whole, Dr. Airy concludes that the history of the early cases appeared to lend some countenance to the theory of aerial infection due to the excavations referred to.

*Sale.*—This township, in the north of Cheshire, is reported by Dr. Parsons to have a flat surface ending on the north in a low escarpment overlooking the Mersey marshes, which are liable to floods, and hence are not built on. The soil is a light porous sand and gravel resting on clay. The town, which has a population of some 8000, is provided with wide streets, a modern system of sewers which is apparently efficiently ventilated and well flushed, and a constant service of wholesome water. In 1880 there were 8, and in 1881 26 diphtheria deaths in Sale, and some 80 cases were reported during the course of the inspection, the disease having been almost continuous during 1881 and the first three months of the present year. Sale is in such relation to Manchester and other populous districts that no information could be elicited to explain the origin of the epidemic. Some of the early cases were found to have been associated with obvious local sanitary defects; but this was not universal, and it is cer-

that the streets in which the poorest and the most careless classes lived did not suffer more in proportion than others. But in two small areas of about 100 to 200 yards radius as many cases seem to have occurred as in the remainder of the district. Here at least, it might have been hoped, lay some explanation of the method of diffusion. But all known hypotheses are discussed in the report without any satisfactory result. Infection from personal intercourse, and especially through school attendance, propagation by wind, the water-supply, the milk-supply, the influence of offensive trades, and refuse accumulations along the canal banks, and the emanations from sewers, are all considered in turn, but with no result. It is, however, shown that in a considerable number of houses in which diphtheria appeared, marked local sanitary defects were found, these consisting mainly in nuisances arising from midden-privies of faulty construction and situated too close to houses, and of defective drains admitting soakage into the subsoil and escape of drain-air into the dwellings. The poison of diphtheria having once found a resting-place in a district, it is notorious that these conditions favour its continuance; and Dr. Parsons points out, as regards Sale, that on the hypothesis that diphtheria has its origin in a living micro-organism, it is conceivable that in a moist and porous subsoil contaminated with decaying sewage matters, this organism may find conditions favourable to its growth and development.

*Sutton-in-Ashfield.*—This small market town is described by Dr. Parsons as having a population of 8523, and as being situated on the western border of Nottinghamshire. It occupies a plateau at an elevation of about 500 feet above the sea; the town itself lying, however, in a depression through which a brook flows. Geologically, the district is chiefly composed of magnesian lime-stone, a fissured and permeable rock, below which are the coal measures; to the north-east of the town are the red marls of the Permian series and the new red sandstone, which latter rock forms to the east healthy gravelly hills. Many of the wells are liable to pollution, cesspool soakage into surrounding soil is not uncommon, slops are thrown about on the permeable strata, many parts of the town are unsewered, and the middensteads are believed to be very generally mere holes in the fissured rock, into which percolation of their contents takes place. Between November, 1881, and the first week of May, 1882, there had been 39 cases diagnosed as diphtheria in thirty households, and 27 cases of scarlet fever in eighteen households. Eleven deaths had resulted from diphtheria and four from scarlet fever. The origin of the epidemic is obscure, and this mainly because of the mildness of early attacks, which were thought only to have been "mumps," but which were shown by such subsequent lesions as paralysis to have been true diphtheria. Scarlet fever seems also to have been inextricably mixed up with the diphtheria, deaths occurring almost simultaneously in the same house being certified as due to "scarlatina maligna" in one case, and to "diphtheria" in another. Indeed, the two diseases were found not only to have existed side by side, but apparently to have been contracted the one from the other, although Dr. Parsons found it impossible to decide whether this had been due to a difficulty in correctly diagnosing between them, or to some mutual or common causation. The mode of spread, too, was by no means clear; but it is surmised that the conveyance of infection from household to household by means of the stocking trade was by no means impossible. Each stocking passes through numerous hands who reside in different houses, and during the epidemic the materials in use certainly passed from infected to hitherto uninfected dwellings, in which disease ultimately occurred. Sanitary defects of a very marked character were found associated with the disease, but it is impossible to say that they were worse in houses having diphtheria than in others which escaped. Certain it is that Sutton-in-Ashfield is in need of an active sanitary administration, and it is especially obvious that it lacks a proper water service.

## VITAL STATISTICS.

### HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns, 5643 births and 3249 deaths were registered during the week ending the 16th inst. The annual death-rate in these towns, which had been equal to 22·7 and 19·9 per 1000 in the two preceding weeks, was 20·0 last week. The lowest rates in these towns were 12·7 in Birkenhead, 15·0 in Cardiff, 15·0 in

Derby, and 15·7 in Portsmouth. The rates in the other towns ranged upwards to 28·4 in Blackburn, 28·6 in Hull, and 33·1 in Sunderland. The deaths referred to the principal zymotic diseases in the twenty-eight towns were 634, showing a further decline from the numbers in recent weeks; 323 resulted from diarrhoea, 93 from whooping-cough, 70 from scarlet fever, 67 from "fever" (principally enteric), 45 from measles, 30 from diphtheria, and 6 from small-pox. The lowest death-rates from these diseases were returned in Plymouth and Bristol, while the highest occurred in Preston and Sunderland. The death-rate from diarrhoea showed a further slight decline from that which prevailed in recent weeks; it was, however, equal to 6·6 in Hull, and 8·0 in Preston; it was nearly three times as high in the twenty-seven provincial towns as in London. The largest proportional fatality of scarlet fever occurred in Nottingham, Derby, and Sunderland; of whooping-cough in Huddersfield and Oldham; of measles in Huddersfield and Sunderland; and of "fever" in Liverpool, Newcastle-on-Tyne, and Sunderland. The 30 deaths from diphtheria in the twenty-eight towns included 23 in London and 2 in Portsmouth. Small-pox caused 3 deaths in London and one each in Leeds, Hull, and Newcastle-upon-Tyne. The number of small-pox patients in the metropolitan asylum hospitals, which had been 114, 101, and 91 on the three preceding Saturdays, further declined to 84 at the end of last week; 10 new cases of small-pox were admitted to these hospitals during last week, against 30, 20, and 9 in the three previous weeks. The deaths referred to diseases of the respiratory organs in London, which had been 202 and 178 in the two preceding weeks, rose again to 192, and were 12 above the corrected weekly average. The causes of 83 or 2·6 per cent. of the deaths in the twenty-eight towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Brighton, Portsmouth, and in eight of the other towns; whereas the largest proportions of uncertified deaths were recorded in Wolverhampton, Oldham, and Sheffield.

### HEALTH OF SCOTCH TOWNS.

The annual death-rate in the eight Scotch towns, which had been equal to 21·1 and 20·1 per 1000 in the two preceding weeks, rose again to 20·9 in the week ending the 16th inst., and exceeded by 0·9 the mean rate last week in the twenty-eight large English towns. The deaths referred to the principal zymotic diseases in these Scotch towns were 103 last week, and showed a decline of 13 from the number in the previous week; they included 47 from diarrhoea, 19 from whooping-cough, 12 from diphtheria, 11 from "fever," 10 from scarlet fever, 4 from measles, and not one from small-pox. The death-rate from these principal zymotic diseases averaged 4·4 per 1000, and was 0·5 above the mean rate from the same diseases in the large English towns. The highest death-rate from these diseases occurred in Glasgow and Aberdeen. The 47 deaths attributed to diarrhoea showed a further decline from recent weekly numbers, but included 19 in Glasgow, and 8 both in Edinburgh and Dundee. The 19 fatal cases of whooping-cough, also showed a decline, 16 being returned in Glasgow and 3 in Aberdeen. The 12 deaths from diphtheria were fewer than in either of the two previous weeks, and included 5 in Glasgow and 2 in Aberdeen. Nine of the 11 deaths from "fever" occurred in Glasgow, while 3 of the 10 fatal cases of scarlet fever were returned in Aberdeen, and 2 both in Glasgow and Paisley. Three of the 4 deaths from measles occurred in Dundee. The deaths referred to acute diseases of the lungs in the eight towns, which had been 30 and 61 in the two previous weeks, were 70 last week, and 9 fewer than those attributed to the same diseases in the corresponding week of last year.

### HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 20·1, 23·8, 27·3, and 27·6 per 1000 in the four preceding weeks, declined again to 25·8 in the week ending the 16th inst. During the first eleven weeks of the current quarter the death-rate in this city averaged 22·8 per 1000, against 18·5 in London and 17·7 in Edinburgh. The 172 deaths in Dublin last week showed a decline of 12 from the number in the preceding week; they included 17 which were referred to diarrhoea, 3 to "fever," 3 to diphtheria, 2 to scarlet fever, 2 to whooping-cough, 1 to measles, and not

one to small-pox. Thus 28 deaths resulted from these principal zymotic diseases, corresponding with the number in each of the two preceding weeks; they were equal to an annual rate of 4.2 per 1000, while the rate from the same diseases was but 2.8 in London and 2.2 in Edinburgh. The fatal cases of diarrhoea, which had been 19 and 17 in the two previous weeks, were again 17 last week; these were equal to a rate considerably exceeding that which prevailed either in London or Edinburgh. The 3 deaths referred to "fever" showed a decline of 5 from the high number in the previous week. The fatal cases of diphtheria and scarlet fever, however, exceeded the recent weekly numbers. The deaths both of infants and elderly persons were less numerous than those returned in the previous week. The causes of 27, or nearly 17 per cent., of the deaths registered during the week were uncertified.

## THE MINUTES OF EVIDENCE BEFORE THE ROYAL COMMISSION ON MEDICAL ACTS.

THE Blue Book of the Royal Commissioners is a volume of 430 pages, and ought to be in the possession of every member of the profession. It is impossible to give even a *précis* of the evidence of the forty-two witnesses examined before the Commissioners. But we are very desirous to make room for some of the evidence on the principal matters involved. We may arrange these under three or four heads. We may assume that the evidence so adduced formed the basis of the recommendations of the Commissioners, and we may hope that it will form the basis of speedy and effective legislation. It is not conceivable, after the evidence given, that things should be allowed to continue as they are. We shall try, then, in three or four successive numbers, to embody the evidence of the principal witnesses on the following points:—

- I. *The inequality of the medical and surgical examinations.*
- II. *The inefficiency of the Medical Council.*
- III. *The mist of the public as to the distinction between qualified and unqualified practitioners.*
- IV. *Miscellaneous.*

First, then, as to

### THE INEQUALITY OF THE MEDICAL AND SURGICAL EXAMINATIONS.

The following are the principal answers on this important subject brought out by the

#### *Examination of Sir JAMES PAGET.*

241. (*Chairman.*) Is not that examination [the Arts examination at the Apothecaries' Society] in some cases too easy?—I believe the examination held by the Society of Apothecaries in London is too easy. The number rejected is, as far as I know, too small, and I think the examination is too easy there. The others I do not know well enough, except that of the College of Surgeons. I believe that at the College the examination is at a fair level, but that it should not be diminished in severity. I cannot at present speak at all of the examination at the end of the first year; that has been held too short a time. The examination held at the end of the second year, that which is commonly called the Primary Examination, is, I think, at this time, at the College of Physicians, a very fair and good one. At the College of Surgeons I think the standard is rather too high. At the last examination, out of 140 candidates, I think not less than 69 were rejected; and I know, by communications with some of the junior teachers in the schools, that there were persons rejected who had worked very hard and passed their examinations in the schools very creditably, and were deemed to be good students, quite safe to have gone on with the rest of their work. I believe, therefore, that though the examination is not defective in its method, it is set at too high a standard. I have not heard the same objections made to the examinations of the same kind in the Scotch corporations; and I fully believe, from all I have heard (but I am bound to say that it is only by report), that they are at too

low a standard. Let me repeat, I only know it by report. Then for the final examination, I think the standard in England is quite high enough, that no one who can pass that examination is likely to be, in any reasonable sense, ignorant of his profession, so far as he requires it for the mere beginning of his work; because it must always be understood that the examination fits a man for the mere beginning of the work in which he has to learn a vast deal more than he has ever learnt before. Again, however, I have to admit reports which I am bound to believe, that in the Scotch corporations they are admitted too low. The reports are distinct statements that the worst of the students in England go to Scotland; that the worst of the students, especially in provincial schools, do not come to the College of Surgeons of England, but go to the College of Surgeons of Edinburgh, or to the Faculty of Physicians and Surgeons in Glasgow. I have never heard any statement of that kind with regard to Ireland. I have never heard any suggestion, I mean in our schools, that the examinations in Ireland are in the least degree less complete than those of England; rather I should have to say, from all I have heard, that the primary examination, especially that in anatomy is better than in any of the corporations in the three divisions of the kingdom.

Professor TURNER questioned Sir JAMES PAGET. The questions and replies are as follows:—

437. You have given us certain impressions as regards the weaker candidates, at least a certain portion of the weaker candidates, not submitting themselves to examination before the College of Surgeons in England, and going to the College of Surgeons in Edinburgh for examination, and I suppose succeeding in passing there?—Yes.

438. Are those mere general impressions, or have you specific cases in your mind? I do not, of course, ask for any names.—I have not names that I can give; but the matter has been frequently talked of, and I have therefore asked teachers, and they have told me that they know instances. I took care to say, in answer to the Chairman, that it was only a matter of belief on my part, but it is a matter of belief on what I think is sufficient evidence.

439. Have you looked at the proportion of rejected candidates who have appeared before the examiners of those different bodies as furnished to the General Medical Council in the annual return?—Yes; I should say, concerning those, that I have never heard that all the bad ones who go from England to Scotland do pass, but when that sum total is made up of rejections, I should not be surprised to find that it came to be nearly as great as the number of rejections in England, because they get such a much worse set of men.

440. Would you be surprised to hear that it is greater than in England?—No, I am not surprised to hear that. I think they get a worse set of men in Scotland, and therefore have to reject a greater proportion than in England.

441. I have only taken the final examination?—I think the other should especially be taken. The final examination is an examination of the men who have passed the first, after the elimination of all the worst, and the worst do not come again.

442. But that applies, of course, to Scotland as well as to England?—But these men go up also for the primary, as I am told.

443. I have not made any calculation upon anything but the final examination?—I could not go further than to say that I have heard it on evidence which I believe. I cannot give you names, and I cannot give you numbers. If it were to be denied and disproved by numbers, I should be surprised; I cannot say more than that.

444. I think, as the matter has been raised, perhaps it might be as well that these numbers should come into the evidence. I find in the final examination of the Royal College of Surgeons of England 37 per cent. of the candidates were rejected?—Yes.

445. I find at the final examination for what is called the double qualification of the Royal College of Surgeons and Physicians of Edinburgh, 44 per cent. were rejected?—Yes. Then may not that be explained on the very ground that I have stated—viz., that in that final examination the rejected on the primary examination in England still remain, and the bad and idle men have gone to Scotland?

446. That I cannot give you any information upon?—That is what is said.

#### *Examination of Dr. JACOB, of Dublin.*

In illustration of his averment of "extraordinary inequality" in curricula and examinations and fees, and of the

tendency of this inequality to drive students from Ireland to easier places, Dr. Jacob adduced a table, in which he traced 2584 Irish students to their qualifying Boards. He says (Question 1374) in answer to the Chairman:—

In drawing up this table, I took the Medical Students' Register, which is published annually by the Medical Council, for ten years, and I picked out from it all the Irish students, numbering 2584; I followed those students into the Medical Register of Practitioners, for the purpose of ascertaining where they obtained their licences, and the table gives an analysis of the information they obtained. I call particular observation to the columns headed "Edinburgh College of Surgeons," and "Edinburgh College of Physicians," and to the figures standing against the Queen's Colleges in those columns, from which it will appear that out of 232 surgical diplomas granted by the Edinburgh College to Irish students, 54 were granted to students of the Queen's College, Belfast, 66 to those of the Queen's College, Cork, and 31 to those of the Queen's College, Galway—that is to say, that 151 out of the 232 came from the Queen's Colleges. Now, if you will permit me, I will explain the reason of that. A student attending in a Queen's College may obtain all the lectures necessary for a Queen's University degree or a Scotch double diploma in two years, not more than two courses of lectures being required in any subject. That student, if he were to come to Dublin, would be obliged to put in a third year, to attend a third course of lectures, pay for his maintenance in Dublin, and pay his fees. Consequently, he does not come to Dublin; but when he seeks a diploma outside his own university, he goes direct to the Faculty at Glasgow or to the Colleges of Physicians and Surgeons at Edinburgh for it. Thus it turns out that a very large proportion of the Irish students have within the last fifteen or twenty years taken their qualifications in Glasgow or in Edinburgh, in consequence of the fact that the curricula there are equal to the curricula of the Queen's Colleges, and below the curricula of the Dublin Colleges. Therefore I use these figures to enunciate the fact that this inequality has been productive of an enormous exodus of Irish students to Scotland, and that if that exodus or that competition of curricula is ever to be put a stop to, it can only be put a stop to by, to a certain extent, equalising the curricula, the fees, and the examinations.

#### Examination of Dr. GLOVER.

1900. (*Lord Camperdown.*) With regard to the examinations by which the qualifications which are given are tested, have you been struck by the inequalities of the examinations of some of the present medical authorities?—I have been struck with the reports of the inequalities. I have had no personal experience of it, and it is very difficult to get personal experience by which to answer that question, but I have been very much struck with the strong impression amongst men who are in a position to be well informed of the existence of such inequality.

With regard to the easy ways of acquiring even the highest qualifications of the Scottish Corporations, Dr. GLOVER said, in answer to Professor TURNER (Question 1979):—

Before the Act of 1858 there were practically no licentiates in the Edinburgh College of Physicians. In 1859, a year of grace, the College made £10,000 by the easy gift, sometimes without examination, of its licence to persons already possessed of a medical qualification. In 1863, the number of applicants for its licence were 160; in 1868, 408. The Royal College of Surgeons, Edinburgh, in 1863 had 132 applicants for its licence; in 1868, 153. This fact has been published lately: A young man went to the College of Surgeons in England, and was plucked. He went to the Edinburgh College of Surgeons, and was also rejected. He went next to the Faculty of Glasgow, and there he got through. He got the licence of that Faculty to practise, and some little time after that he was found in possession of the Fellowship of the Edinburgh College of Surgeons—the highest qualification which it had to give. That has not been contradicted.

#### Examination of Dr. HALDANE.

2774. (*Bishop of Peterborough.*) If we had a *tabula rasa*, we should not begin by setting up the nineteen medical bodies?—Certainly not.

2775. And I think I may assume further from your evidence that the degrees or diplomas given by these various medical bodies, and therefore presumably the education on

which they have given those diplomas or those degrees, vary very considerably in value?—They vary undoubtedly.

#### Examination of Mr. SAMFSON GAMGEE, F.R.C.S. Eng.

3228. (*Chairman.*) Can you tell us from your own experience instances of persons who have chosen examinations which are notoriously inferior?—I have known many men who have been unsuccessful in the English examinations—e.g., the examination of the Royal College of Surgeons—once, twice, and thrice go across the border and come back with the double qualification from the Edinburgh and the Glasgow Colleges.

3229. When you say "Colleges," do you mean the Corporations or the Universities?—By the Colleges I do not mean the Universities. So far as I know of the Scottish Universities, their position is unimpeachable. But with regard to the Colleges of Physicians and Surgeons of Edinburgh and the Faculty of Physicians and Surgeons in Glasgow, I have known men get through there who had failed in our College of Surgeons repeatedly, and I have no hesitation in saying they were men who were entirely unfit to enter the medical profession. That has happened within the last three or four years. I have addressed my classes several times during the last seven or eight years—that is to say, successive classes in different sessions—and I have assured them that whatever they said to me would be in confidence so far as persons were concerned. I said, "How is it that A.B. went to Edinburgh or Glasgow; can you tell me anything about what is the feeling of the students on the choice of examinations?" They have said, "We know very well that the Scotch Colleges give the easiest examination; if a man is plucked here, he can go there, and," to use a student's expression, "bring his ticket back."

3230. Do you say that with regard to the Colleges of Physicians and Surgeons at Edinburgh?—Yes, I do.

3231. That statement is made upon cases which have come within your own knowledge as a teacher?—Yes, I speak of men that are now upon the Register. I have refreshed my memory by looking to see if they are still alive, and I know the men perfectly well.

3232. Do you think there are many instances of that kind?—I know several, and it is a notorious fact that there are a great many. It has a most demoralising effect. When a young student, beginning with good intentions, gets into some little difficulty with his studies, and cannot go up for the first Anatomical Examination at our College, he is consoled in this way: the College of Surgeons of England will only give him a single qualification, but he can go to Edinburgh and bring back a double one on very much easier terms.

Professor TURNER, examining Mr. GAMGEE, said:—

3373. Then you have also made certain statements as regards the migration of students from England to Scotland in order that they may obtain in Scotland a less difficult examination than they would have to be subjected to in England?—I have done so.

3374. Have you any reason to believe that those examinations to which you refer are inefficient examinations; that is to say, that they do not sufficiently test the competency of the candidate to practise medicine, surgery, and midwifery?—I know that they have let through some altogether incompetent men, who could not get through the English boards.

3375. Do you know that of your own knowledge?—I do.

#### Examination of Professor SPENCE.

3434. It has been stated to us in evidence by some of the witnesses that it is notorious that some institutions give diplomas on much easier terms than others, and that it is well known both to students and to teachers that many men who would have no chance of passing in some institutions go to others and pass?—That is a strong assertion without much proof, and I would ask for proof, for I do not know of anything of the kind taking place, and I do not believe in it. From what I have seen of the examinations of all the boards with which I have been connected, and from what I know of the others, I do not know of any in the United Kingdom where that is the case. A man cannot practise even on an apothecary's licence alone, which might have been a little easier formerly. I know that when I was a teacher of anatomy, with regard to the English College, there certainly was a tendency on the part of a portion of the students to go there, and if one asked a student why he went to the English College instead of

remaining where he had studied, he would say, "Well, I may practise in England; and another thing is, that when I go to the London College of Surgeons (when it was the London College of Surgeons, not the College of Surgeons of England), I have only to be examined in anatomy, physiology, and surgery, and I can get that up more easily than when I go to the Edinburgh College, where I have so many more subjects." But that is different now; I do not think there is any tendency to that. I am quite sure that no man goes to one place more than another on that account; if he does, he finds it a very gross delusion when he goes to the particular body which he has chosen.

3435. In your opinion, I presume, as far as possible there should be equality in the curricula of studies in all the institutions?—Yes, certainly, I think that is a matter of very great importance.

3436. And that the time necessarily taken in going through the medical course should be the same in all?—They should be regulated as far as possible to be the same.

3437. And as far as possible the expense and the fees should be similar?—That would depend very much upon whether it is a wealthier or a poorer country; but, no matter what the fees are, I think that in the curricula of study and the examination there should be an equality.

3438. If it should be that a conjoint board were established, do not you think that a conjoint board consisting partly of the universities and partly of the medical corporations would be stronger than either by itself?—No. I think that the examinations would deteriorate. At present an examiner connected with a college or a university has the honour and traditions of the college in his hands, he feels himself responsible, and he knows that he is responsible to the college that elects him from year to year, and consequently he is more particular in doing his duty. There is a sort of *esprit de corps*, in fact, with regard to examination which, I think, keeps up the examination both in the universities and in the colleges to the high standard which at present obtains. It would be a mere examining board; you would have people examining who have no interest in the business; at first it might be very good, for we are told that new brooms sweep clean, but afterwards the men would gradually lose their interest, and the examination would become perfunctory after a time. You might get first-rate men to examine at first, but you would find that what took place in Prussia would take place here. Formerly in the Staats Examen they were required to have some of the best men that they had in Prussia as examiners, but they found that those men after a time gave it up; they had not time and they got tired of it; they literally gave it up, and the examiner goes now to the universities and to the different schools which give a licence, so that that system broke down there, and the Staats Examen broke down, so far as being a single portal, as it were, to the different universities. I think there are some nineteen or twenty boards at least in Germany now.

3439. Do you approve of the higher honours of the profession being given through examination?—The question is, what is meant by an honour?

3440. For instance, a Fellowship in a college?—Fellowship of a college does not necessarily imply a qualification to practise. At the time I entered my college I entered of course by examination, and that kept me back for fifteen years nearly in my profession from the expense connected with it. I do not think that you have a right to saddle any man with expense on entering the profession in that way, so that he cannot get on unless, as a condition of his entering the profession, he can afford to spend so much more time in study, and so much more money for such a degree. If a man wants a higher degree let it be Doctor or Master in Surgery. The title of Fellow merely implies that he is an associate, for that is the simple meaning of it. It does not imply a higher degree; it simply implies that a man has such an interest in the particular profession that the college think he is worthy of being affiliated to it. I have handed in a statement along with my *précis* which was sent by the College of Surgeons in Edinburgh, which I may just as well refer to. This statement was drawn up in consequence of certain very misleading statements, for I cannot call them anything else, that were made with regard to our Fellowship. I urged the present Council to meet them, and they referred it to me. I went over the history, because I knew the history of it from the commencement. When the charter was granted I was a young Fellow of the College, but still I was there during all the debates, and heard the reasons given in

the College, and I recollect the history very well. I considered that the College of Surgeons of Edinburgh, through their monopoly, were keeping back their licentiates, because I felt that unless I could afford to pay £300, which I had to do ultimately, I had no chance of obtaining a Fellowship, and I think that was a very great hardship. In the English College of Surgeons now there is no such direct money charge, but if we can believe those who make the statement, they say that it costs between £300 and £400 for extra medical education for a man to be able to go in for that examination, and I say that you have no right to put such a money barrier in the way at the commencement of a man's professional life. A man who is able to treat Her Majesty's subjects ought to be able to be a Fellow or an associate of a college without any further examination. Of course, I do not stand upon examination. A man should be thoroughly examined before you send him to the country as a practitioner, and then after that let him be affiliated to a college by some other means than examination.

3441. You are aware that the College of Surgeons in England takes a different view from what you do, and that they do not confer their Fellowships without a very strict examination, and that they believe it a higher honour, and therefore that it ought to be to the public evidence of a higher qualification?—But it is not so. It is not so in the present system of the College of Surgeons of Edinburgh, and we have had experience of both systems. We had experience of what it was by examination, and we found that the College was dwindling away—that nobody joined it. Men in practice who had a good reputation would not go there and submit themselves to the examination. Men who had been in practice as hospital surgeons in some of the provinces found that it conferred no privileges on them, except in Edinburgh, when the surgeon wanted to hold a hospital position there. That was a great hardship to those who had not the money qualification in the first instance, and that is what kept me back for years before I could become a surgeon to a hospital.

(To be continued.)

## THE GENEVA CONGRESS.

### No. II.

#### M. PASTEUR ON THE ATTENUATION OF VIRUS.

AT the second sitting only was the real business of the International Congress of Hygiene begun. The first meeting was devoted to congratulatory addresses, in which it was curious to notice that the least important countries took the most active part. While the representatives of the Great Powers of Europe maintained an attitude of solemn reserve, Poles, Bulgarians, Brazilians, representatives from Algeria and similar countries, indulged in grandiloquent speeches, which might have conveyed the impression to an ignorant public that the spirit of sanitary reform had been imported into Western Europe from the Danubian Principalities and regions south of the equator.

The second meeting of the Congress was densely packed; in the galleries occupied by the general public there was scarcely standing room. The heat of course was intense, and the impartial critic must have discerned that if sanitary reformers are good speakers, they are, so far as the ventilation of the hall where they met is concerned, anything but good practitioners. Dr. H. C. Lombard, of Geneva, the President of the Congress, was in the chair, and when he called M. Pasteur to the platform, the applause assumed the character of an ovation. Discarding all attempts at oratorical effect, M. Pasteur took a seat at a little table, unfolded his manuscript, and read as quietly and simply as if he had been at his own fireside. Now and then he stopped in the lecture to explain some point, or else to abbreviate some passage which he thought too long. Yet if the speech was thus modestly delivered, it was not devoid of that refined eloquence that is the special charm of a cultivated Frenchman. To explain his presence, M. Pasteur commenced in the following words:—"The Directing Committee of this Congress, knowing that I was to spend the vacation in the Jura mountains, within a few hours of your beautiful city, was kind enough to invite me to read a paper on the Attenuation of Virus. I willingly acceded, happy to find a

pretext which would enable me to become for a little time the guest of a people who had been the friends of France in its evil as in its prosperous days. I also cherished the hope of meeting those who have criticised my works during these last few years. If this Congress is a field for union and reconciliation, it is also the arena for courteous discussion. We are all animated by the highest aspiration—a passionate love of truth."

M. Pasteur then at once launched into the subject under discussion, recalling his works published in 1880 on Chicken Cholera, the cultivation of the specific germ, and the creation by this cultivation of a virus that could be used as a vaccine against the disease. This modification in the intensity of the germ poison could be obtained by simply exposing the microbe to the action of oxygen. This fact had also been proved as applicable to the microbe of charbon, by comparing the virulence of cultivated microbes exposed to the action of the air and those which, on the contrary, have been confined in a sealed tube. In the former case they perish entirely in the course of a few months, after passing through various phases of attenuation; while the latter, being protected from the action of oxygen, retain their virulence for several years. M. Pasteur's principal object was to demonstrate that by utilising the action of air we could establish a general method for the attenuation of virus. In the researches which have demonstrated these facts, M. Pasteur was greatly assisted by M. Chamberland, M. Roux, and more particularly by M. Thullier. It was in their name as well as his own that he spoke. M. Pasteur then related the case of a young child bitten by a mad dog, and who died of hydrophobia. Rabbits inoculated with the saliva taken from this child, four hours after death, died in thirty-six hours. This blood contained a special microbe that could be easily cultivated, and in each successive generation killed rabbits thus inoculated, and the same microbe was discovered in their blood. In one experiment it was shown that the appearance of the virulent organism took place nine hours after inoculation, and corresponded with the commencement of the fever. The saliva of dead rabbits will communicate the malady to other rabbits. Adult guinea-pigs can resist this inoculation, but young guinea-pigs are killed in two or three days, and by passing the poison through several young guinea-pigs it so increases in violence that it will ultimately kill adult animals of the same race; but, strange to say, if it is brought back again to rabbits, then it loses its poisonous force. M. Pasteur described this microbe at the Academy of Medicine on Jan. 18th, 1881.

The question arose whether this microbe would always present itself in cases of hydrophobia, and as in February, 1881, another child died from the bite of a mad dog, other inoculations were made with the saliva taken both before and after death. The rabbits died in three days, and the same microbe was discovered in their blood. Prolonged experiments with the saliva of rabies showed that death might result in three ways: (1) by the new microbe; (2) from disorders of a purulent and septic character; (3) from true madness, which always requires a long period of incubation, and commences by paralysis of the limbs twenty-four to seventy-two hours previous to death. The tendency to bite is extremely rare among mad rabbits. Therefore M. Pasteur concludes that the saliva of persons dying of hydrophobia contains, apart from the specific virus of rabies, not yet characterised by a cultivatable microbe, a virus formed by a special cultivatable microbe, and other and various microbes capable of occasioning death by the exaggerated production of pus, by excessive local disorders, and sometimes by the introduction into the blood of ordinary microbes. The new microbe discovered in the saliva of persons suffering from hydrophobia has subsequently been found in the saliva of persons who died from other diseases; it therefore accompanies, but has no special relation with, the virus of rabies. Nevertheless, this is the third virulent microbe which can be attenuated by the action of oxygen, and the history of this third microbe is as yet unpublished. M. Pasteur offered the Congress the first record of these new experiences. He found that the microbe of the saliva was governed by the same laws as those that influenced the virulence of the microbe of the cholera in chickens. M. Thullier had the patience to cultivate eighty generations of microbes found in the saliva of a patient who died of hydrophobia, and the eightieth generation was as virulent as the first. But if the successive cultures are submitted to the action of air, then

the result is not similar to that obtained with the microbe of chicken cholera. The microbe from saliva dies very rapidly. Two or three days' exposure to air often suffices to render the microbe sterile. A culture coming from virulent blood will live from six to twelve days, but in each successive batch the duration of virulence is reduced. The eighth generation will not live longer than three or four days; the twenty-fifth, twenty-six hours; and the forty-eighth, twenty hours. These latter cultures, if inoculated in rabbits, will not always kill them, and the rabbit, having survived the mild inoculation, can then take the virulent poison with impunity. Yet the rapidity with which this microbe loses its virulence renders it very difficult to discover the moment when in its increasing vitality it would constitute a safe vaccine. To do this it is necessary to prolong the life of each crop. This great end can now be attained by employing a new vehicle. The microbes generally live best in veal broth; but by mixing two parts of this broth with one part of pure rabbit's blood, M. Pasteur finds that the life of microbes derived from saliva can be prolonged to forty or fifty days. By taking the microbes during the last ten days cultures of graduated virulence can be made, and thus a vaccine of various degrees of strength obtained. It is to the action of oxygen that we must again attribute the modified strength of these cultures. To the microbes mentioned—the microbe of chicken cholera, the microbe of charbon, the microbe of saliva, especially the saliva of rabies—M. Pasteur concluded by adding a fourth microbe that was discovered in the foam taken from the nostrils of the horses that died during the typhoid epidemic at Paris in 1881. By inoculation with this germ rabbits died of true typhoid. With infinite pains M. Pasteur succeeded, and still by the use of oxygen, in so cultivating and reducing the virus of the typhoid microbe, that he was at last able to vaccinate rabbits without killing them; but, on the contrary, when he subsequently inoculated them with the virulent poison, they did not feel its effects. Thus M. Pasteur was able to declare, in conclusion, that we now undoubtedly possess a general method of attenuation. Its application need only be modified according to the exigencies of the physiological characteristics of the different microbes. The general principles have been found, and it is impossible to doubt that the future of these researches is rich with the promise of great results.

M. Pasteur then proceeded to refute some personal attacks made against him by Professor R. Koch and his pupils. This gave rise to a curious misunderstanding that, but for the dignified reserve of Dr. Koch himself, might have led to unpleasant consequences. The Germans, who were present in great numbers, misunderstood M. Pasteur's allusion to the *recueil allemand* as a taunt respecting the *orgueil allemand*. After such a misconception, Dr. Koch was perhaps justified in refusing to accept M. Pasteur's challenge, though he at once mounted the platform after the applause had subsided.

Dr. Koch, speaking in German, said he was disappointed with M. Pasteur's paper; the facts lacked novelty, and he could not see that they were especially connected with hygiene. In any case, he would answer all the points raised through the medium of the scientific press. Dr. Koch was especially anxious to avoid a discussion at present, for, as M. Pasteur could not speak German, and he could not express himself clearly in French, there was but little chance of coming to an understanding.

M. Pasteur thereupon protested that Dr. Koch could not have understood his paper, or he must have acknowledged the importance and fecundity of the facts disclosed.

The President here adroitly interposed, suggesting that a diversity of opinion between men so prominent in science could but prove of benefit to mankind by stimulating the researches of each party.

Dr. Sormani, of Pavia, then related how in Italy it had been found that the vaccine for charbon was only effective when it produced sufficient disturbance to raise the temperature of the animal vaccinated to 40° C.

Dr. Marestres, of Genoa, doubted whether the microbe was the cause of illness. The microbe of typhoid, for instance, was not found at the commencement of the illness. Just as the sea was not made by the fish but for the fish, so did the microbe live in diseased blood because it suited its mode of life, and not because it had created the disease.

M. Pasteur, in answer to the suggestion that his researches were not connected with hygiene, urged that as their object

was the prevention of disease, they, on the contrary, harmonised with the highest aims of sanitary reform. Already some practical results have been attained, for there have been no less than 400,000 sheep vaccinated and 40,000 bullocks, and the deaths from charbon have been reduced to 1 in 300 among the sheep and 1 in 2000 among the bullocks. There have been, it was true, unfavourable results in Italy, but this was due to mismanagement; the vaccine had been kept too long in a hot climate, and was charged, not merely with the microbe of charbon, but with many septic germs.

At the conclusion of a most enthusiastic meeting M. Pasteur was warmly felicitated on all sides.

## THE SERVICES.

**ARMY MEDICAL DEPARTMENT.**—Brigade Surgeon Adam Graham Young to be Deputy Surgeon-General, vice J. P. Cunningham, M.D., granted retired pay; Surgeon-Major William Silver Oliver, M.D., to be Brigade Surgeon, vice A. G. Young.

**ARTILLERY VOLUNTEERS.**—1st Hampshire: Honorary Assistant-Surgeon David Shorter Skinner resigns his commission.

**RIFLE VOLUNTEERS.**—1st Roxburgh and Selkirk (the Border): Surgeon Alexander Dewar, M.D., resigns his commission.

**ADMIRALTY.**—In accordance with the provisions of Her Majesty's Order in Council of April 1st, 1881, Fleet Surgeon George Moore, M.D., has been placed on the Retired List from the 13th inst., with permission to assume the rank and title of Retired Deputy Inspector-General of Hospitals and Fleets.

The following Staff Surgeons have been promoted to the rank of Fleet Surgeon in Her Majesty's Fleet:—George Curtis, George Bewsher Beale, M.D., John Stephen Dobbyn, M.D., and George Robertson, M.D.

The following appointments have been made:—Fleet Surgeon Edward H. Evans, to the *Durham*, vice Moore; Surgeon Gerard J. Irvine, to the *Diamond*, vice Stace, invalided; Staff Surgeon Edward W. Doyle, to the *Heroine*; Surgeon Joseph Crowley, to the *Linnet*; Surgeon Henry G. Jacob, to the *Duke of Wellington*, vice Doyle; Fleet Surgeon William Roche, to the *Impregnable*, vice Hadlow; Staff Surgeon Edward T. Lloyd, to the *Brilliant*, for temporary service; Staff Surgeon Anthony Gorham, M.D., to the *Osprey*.

## WILLS AND BEQUESTS.

THE Irish Probate of the will of Surgeon-Major Espine Ward, Army Medical Department, who died at Barbadoes, West Indies, granted to his brother, Mr. Montgomery Albert Ward, M.B., was sealed in London on the 16th ult., the aggregate value of the personal estate in England and Ireland exceeding £1200. The testator's wife, who under the will took a life interest in his property, having died, all his estate becomes at once divisible between his children.

The will of Joseph Peplow, M.D., formerly of 111, Great Russell-street, Bloomsbury, afterwards of Eastbourne, but late of 7, Vant-terrace, Lower Tooting, who died on July 27th last, was proved on the 18th ult. by Mr. Edward Peplow, the nephew, and Mr. John Eyles, the executors, the value of the personal estate being over £4900. The testator, after making bequests in favour of his wife, Mrs. Phoebe Peplow, and of his adopted children, Victoria Alma Williamson and Charles Frederick Joseph Williamson, leaves the residue of his property upon trust for his sister, Mrs. Elizabeth Eyles, for life, and at her death for six of his nieces.

The will of Alfred Heale, retired surgeon, formerly of Luton, Beds, but late of Jury-street, Warwick, who died on June 15th last, was proved on the 28th ult. by Mrs. France Heale, the widow, and Mr. Charles Crichton Stuart Benning, the executors the value of the personal estate amounting to over £13,000. The testator gives to his wife £2000 and all his household furniture, plate, and effects; to his nephew, Alfred Lawson Heale, £800; and a legacy to his brother. All his real estate and the residue of the personalty is to be held upon trust to pay the income to his wife for life; at her death further legacies become payable, including £2000 to

his said nephew; and the ultimate residue is to be divided between his sister, Miss Agnes Heale, and the children of his late brother, Arthur Wellington Heale.

The will of Henry Davis Male, M.D., of 2, North-side, Victoria-park-square, who died on July 28th last in Somersetshire, was proved on the 7th inst. by Mrs. Juliana Male, the widow and sole executrix, to whom he devises and bequeaths all his real and personal estate for her own use and benefit.

The following legacies have recently been left to hospitals and other medical charities:—Mr. Thomas Higginbotham, of Alderley Edge, Cheshire, £300 each to the Manchester Royal Infirmary and the Macclesfield Infirmary, and £100 to the Children's Hospital at Pendlebury.—Mr. John Eyston, of Salford Hall, Warwickshire, and Welford, Northamptonshire, £100 to the General Infirmary, Northampton.—Mr. John Robert Daniel Tyssen, of 9, Lower Rock-gardens, Brighton, £200 to his niece, Caroline Harvey Carter, for the benefit of the Cottage Hospital at Tavistock.—Mr. John Hyam, of 60, Hounds-ditch, and 53, Tavistock-square, £100 to the Jewish Hospital.

## SCOTTISH NOTES.

(From our own Correspondent.)

ON Sept. 4th a prediction appeared in the *Scotsman* that after that date we would have a period of dry but rather cold weather, suitable for harvest operations. It was written when farmers' hopes were not high; as the week had been wet and changeable. The opinion was based on spectroscopic observation, showing that a change in the percentage of rainfall had taken place, and that this was then much less than it had been. The Meteorological Office has been peculiarly in error in its predictions, showing that some essential factor in the calculation had been omitted, and this, together with the period of the year, gave additional interest to the observation. For a complete week harvest work was entirely uninterrupted; on Sept. 10th we had a considerable rainfall, and after this it was four days before rain again fell, so that the first public weather prediction which, so far as I know, we have had in Scotland by this new method has proved eminently correct.

A serious accident occurred to Mr. W. A. Orr, M.B., Johnstone, last week. It would appear that while on holiday he had been putting to the test the leaping capabilities of a horse recently purchased, that the animal shied and fell, rolling over his rider, and causing a double fracture of the clavicle as well as some rather serious bruises. He is progressing favourably.

A complaint having been made to the Board of Supervision regarding the manner in which Dr. Marshall, of Dumfries, has performed his duties as parish doctor, an inspector visited the town a few days ago for the purpose of taking evidence in the case. The charge of neglect is made by another practitioner in the town, Dr. John Cunningham, who appears, in correspondence with the Board of Supervision, to have asserted that the poor of the burgh have had the greatest difficulty in securing the services of Dr. Marshall; and it is further charged against that gentleman that he went to Ireland without providing a substitute to act in his absence, Dr. Cunningham's services being put in requisition. It is of the utmost importance that the poor should be suitably attended to, and, happily, complaints of this nature are rare, while it is still more seldom that a fellow practitioner is the informer. Dr. Marshall will doubtless have a thoroughly impartial inquiry; and if it is true, as I hear, that this gentleman enjoys but indifferent health, he will receive the sympathy of his neighbours, who seem to think that Dr. Cunningham's interference might have ended when his work was done.

Notwithstanding remonstrances from various quarters, and the influence of a large minority in their own body, the Dundee Police Commission have separated the offices of police surgeon and medical officer of health, giving to the latter but a trifling salary, and losing the opportunity of placing health matters on a satisfactory footing, as recommended in THE LANCET. The present muddled condition of the public accounts has evidently a good deal to do with the result, and I hope that as the financial state improves so will the salary of the gentleman now appointed. It is noticeable

that, though the salary offered was so shabby, two of the best men in the town were candidates: a fact which is rather unpleasantly suggestive to other cheese-paring communities.

I hope that the handsome gift of £2000 now received by the Aberdeen University from Mrs. Marr, for the founding of medical bursaries, may soon be imitated by other friends of the University and of science. In the Arts and Divinity classes almost every student holds a bursary, but such are so scarce among medical students that this may almost be considered a new departure.

The epidemic of typhus fever in Aberdeen which recently threatened to assume serious proportions has now been stamped out. Dr. Simpson complains of the prevalence of overcrowding and deficient ventilation, shows their influence in the spread of typhus, and suggests the clearing out of a number of the courts in the poorer districts of the city as the only means of accomplishing a more sanitary condition.

### PARIS.

(From our Paris Correspondent.)

DR. DE PIETRA SANTA, after having discoursed at the last meeting of the British Medical Association on the etiology of typhoid fever, showed the relative value and importance of the two principal theories in vogue as to the nature and cause of this virulent form of fever. On his return to Paris he followed up his paper at the Academy of Sciences and the Academy of Medicine, which will, I presume, go the round of the medical societies here. He placed in juxtaposition what he calls the English and the French theories: the former maintaining that typhoid fever is produced by direct contagion, by the stools of the patient and the elaboration of morbigenic matter which is generated in the different pipes and drains of dwelling-houses, or in the collectors of sewage water. In other words, the English theory may be said to consist—first, in impure and contaminated drinking waters; secondly, in the exhalations from sewers, or from the miasmata emanating from privies and cesspools. The French theory admits that typhoid fever may be developed spontaneously by infection, or specifically by contagion; but the great majority of French authors do not accept the unity of the typho-genetic poison. Thus it may be seen that Dr. de Pietra Santa has not thrown any new light on the subject; he has not disproved the English theory, and I do not find that he has enunciated anything novel concerning the French theory, which denies that the cause of typhoid fever consists of a germ, or of any single preformed agent entitling it to be considered as an exclusive or specific cause of this virulent type of fever.

Up till now the bromide of potassium has been almost the only remedy employed in the treatment of epilepsy, but Professor Ball has found from experience at his Clinic at the St. Anne Asylum that the combination of the bromides of ammonium and sodium possesses an incontestable superiority over the potassium salt, the two former being much better borne by the stomach. Another advantage of this double salt is that it does not leave, after its employment for a time, either headache, drowsiness, languor, loss of memory, or any weakness of the intellectual faculties. Moreover, although the double salt also produces an acnoid or a furuncular eruption, yet neither the one nor the other form of eruption occurs with such frequency or intensity as with the bromide of potassium. The double salt, however, has one great drawback to which Professor Ball has directed attention, and that is its tendency to produce hæmorrhage, or to aggravate this when it exists already. He therefore considers it an unsafe remedy in tubercular or phthisical subjects, and in such cases he gives the preference to the bromide of potassium.

Your readers will recollect the history of the "homme à la fourchette," which created a great sensation a few years ago. We have now a patient in the Lariboisière Hospital who has been operated on by Dr. Felizet for the removal of a spoon from the stomach. The patient was a waiter at a café, who in a frolic accidentally swallowed a spoon. It was a spoon generally used for mixing toddy or diluted coffee, the bowl of which is about the size of a teaspoon, with a handle adapted for a long tumbler. Dr. Felizet at first was in hopes that he would have been able to remove

the spoon through the natural passages; but finding this impossible from its position, which was across the stomach, he was obliged to resort to gastrostomy. The patient, according to the latest report, is doing as well as can be expected.

The death of the oldest physician in France, Dr. Dorin, is reported, which took place at Chalons-sur-Marne. The venerable doctor had just attained his ninety-fourth year.

While in the act of holding his consultations, Dr. Hillairet died suddenly on the 15th inst. from an attack of apoplexy. The deceased physician was scarcely sixty, and appeared in robust health. He was for a long time physician to the Saint Louis hospital, and a member of the Academy of Medicine since 1875 in the section of Public Hygiene.

## Obituary.

SIR JAMES ALDERSON, M.D. OXON., D.C.L., F.R.S.

SIR JAMES ALDERSON, who has just died at the advanced age of eighty-seven, was almost unknown to the present generation of medical men, but will be well remembered by the senior Fellows of the College of Physicians. He was a man of considerable ability, took a high position in the list of Wranglers at Cambridge, and was made a Fellow of Pembroke and of the Royal Society. He took his degree in medicine at Oxford in 1829, and became a Fellow of the College of Physicians in 1830. For many years he practised in Hull, where he held a very high position. He is said to have had a large and lucrative practice there, and his reputation still survives in the East Riding of Yorkshire and in Lincolnshire. He left Hull, however, for London, and at once began to take an active part in the government of the College of Physicians; the College, indeed, appears to have been his chief interest, and until the time when he ceased to be president, in 1870, after three years' tenure of that office, there were few figures more familiar than his in the College building. He was treasurer from 1854 to 1867, and devoted much time to the duties of the office, which he discharged with zeal and skill. It was he who discovered the original charter of the College, given by Henry VIII., which is now among its treasures.

When St. Mary's Hospital was founded in 1851 he was selected for the highest place on the medical staff, and continued to be senior physician till he became president of the College in 1867.

In person he was below the middle height, and slight in build; and he was remarkably active, and even agile, when he had long passed the age of sixty. His face gave one the impression of intellect and power; his features were regular and well cut; his expression was, perhaps, a little haughty.

In practice he did not rely much on physical examination, but his diagnosis was remarkably good, and his prognosis was usually verified by the result. His bedside teaching consisted of a few shrewd remarks which often conveyed most valuable lessons. At the College of Physicians he distrusted the reforms which led to its existing constitution; but he had its interests thoroughly at heart, and his labours on its behalf were recognised by his election as president on the retirement of Sir Thomas Watson. He held this office for three years, but was not re-elected for a fourth term. From this time he was rarely seen at the College, and it is doubtful whether he ever attended another meeting of Comitia. It was on his retirement from the presidency of the College that he received the honour of knighthood.

Sir James Alderson has left no writings which are likely to be of permanent value, but though he may have made no durable mark in his generation by this or other means, he was a useful member of the profession and a man of a high sense of honour, and his memory is held in great regard by many of his colleagues in the College of Physicians and of the former students of St. Mary's Hospital.

ROBERT RAYNER, M.R.C.S., L.S.A.

THE inhabitants of Birstal and of the immediate vicinity have sustained a serious loss by the death of Mr. R. Rayner. The deceased, who was the eldest son of the late Mr. Thomas Ingham Rayner, was born in 1825.

Mr. Rayner became a Licentiate of the Apothecaries' Society in 1848, and a Member of the College of Surgeons in 1850. For many years past Mr. Rayner, first alone, and afterwards in connexion with his son-in-law and surviving partner, Dr. Forsyth, had a large and varied practice, and enjoyed the respect and esteem not only of his patients but of his professional brethren. Mr. Rayner held the post of certifying surgeon under the Factories Act from 1854 to 1879, when he resigned the appointment in consequence of declining health. He was medical officer for the Birstal District of the Dewsbury Union from 1850 to the date of his death; medical officer of health in the Local Board Districts of Birstal and Birkenshaw, and for some years also held that position in the adjoining township of Drighlington. The energy and abilities of the deceased were not, however, confined to the duties of his profession. Mr. Rayner was elected to the office of churchwarden on nine different occasions, trustee of the Day and Sunday Schools, a vice-president of the Birstal Church Institute, and was also actively engaged in all measures affecting the parish church where lay assistance was necessary. In connexion with the volunteer movement in Birstal, Mr. Rayner held the following offices—namely, surgeon to the 30th West Yorkshire Rifle Volunteers, lieutenant, captain, and then major of the corps. On being raised to the rank of major he was presented with a testimonial by his brother officers and the other members of his corps, and he continued to hold that position for some years. In October, 1875, the deceased met with a serious accident by being thrown from his carriage—an event which induced a condition of ill-health that terminated fatally on the 8th inst. That Mr. Rayner was universally esteemed in the district was amply shown by the large attendance of spectators of all ranks and positions in life at his funeral, which took place at the parish church on the 13th inst.

#### THEODORE E. D. BYRNE, J.P., L.R.C.P.ED., M.R.C.S.

MR. BYRNE, of Elsiehiels, Dumfriesshire and Drumness, Kircudbrightshire, died at Saltcombe, South Devon, on September 9th, at the comparatively early age of fifty-three years. His health had for some years been far from robust, but the lung mischief which proved fatal only lasted three days. Though of an old Scottish family, the deceased was born in Dublin, where he resided for several years, afterwards spending a considerable time in foreign travel. Having studied medicine at Newcastle and obtained his licence, he served throughout the Crimean war, obtaining a medal in recognition of his services. His next few years were passed in the merchant and emigrant services, after which he settled in practice at Newcastle, till, on the death of his father in 1876, he succeeded to the family estates, when he settled at Elsiehiels. Retirement and leisure being un congenial to such an active man as Mr. Byrne, he devoted himself to the consideration of local matters, to which he imparted a lively interest. He contested the Dumfries burghs in 1880 as an independent Conservative candidate, but though his meetings were much enjoyed by those who loved quick repartee and veracity, his candidature was not considered serious, and at the poll he could only command about fifty votes. Locally he had little fellowship professionally, but from the various forms of activity manifested by him, and his trenchant criticism of men and manners, his place will be difficult to fill.

### Medical News.

**APOTHECARIES' HALL.**—The following gentlemen passed the examination in the Science and Practice of Medicine, and received certificates to practise, on Sept. 14th:—

Blaikie, William, Oswestry.  
Muddle, Edward John, Queen's-road, Dalston.  
Parry-Jones, William Richard, Rhos, Ruabon.  
Pryce, Thomas Davies, Newtown, Montgomeryshire.  
Willet, George Gilman Drake, Bristol.

AT a Cripples' Home in London (says the "Daily Chronicle") it was ascertained by a lady some years since that most of the inmates whose deformity was not congenital owed their misfortunes to the overturning of perambulators, or to falls out of them.

MRS. TOWNEND, of Puckrup Hall, has given £1000 to the Rural Hospital and £250 to the Dispensary of Tewkesbury.

A SUCCESSFUL trades demonstration, in aid of the funds of the Halifax Infirmary, took place at Elland on Saturday last.

**NEGLECT OF VACCINATION.**—The number of unvaccinated children in Cleckheaton, Yorkshire, has induced the guardians of the district to make special efforts to obtain compliance with the law on the part of defaulters, to whom more than a hundred notices have been issued.

MAJOR TULLOCH, on behalf of the Local Government Board, has been inquiring into the condition of the water-supply of Hawarden, with the result of showing a great need of improvement in that particular. In times of drought the inhabitants of the district appear to have been dependent on the neighbouring ditches for their supply of water for drinking purposes.

THE sum of 400,000 dollars has been bequeathed by the late Mr. William Euston, a native of Canterbury, but who realised an enormous fortune in the United States, for the purpose of founding a hospital for aged and infirm persons in Charleston, South Carolina. The testator desired that the building should be of a character similar to one existing in his native city.

THE death-rate in New York appears to have been exceptionally high last year. According to Consul-General Archibald's report the rate of mortality rose from below 26.50 per 1000 in 1880 to above 30 per 1000 in 1881. Half the number of deaths from zymotic diseases, amounting altogether to 13,496, were attributed to diphtheria, scarlatina, and diarrhoea.

ON the 14th inst. a new children's ward at the West Kent General Hospital, at Maidstone, was declared duly open. The ward has been erected to the memory of a Maidstone working man, Jonathan Saunders, now deceased, who, during a busy lifetime, spent his leisure hours in advocating the cause of this and other hospitals. A working men's subscription to the fund for erecting the ward realised more than £350.

**THE NORTHERN SANITARY ASSOCIATION.**—This Association has now got into working order. At a recent meeting of the executive committee, Mr. Fleeming Jenkin, M. Inst. C.E., professor of civil engineering in the University of Edinburgh, was appointed consulting engineer. Mr. Coard S. Pain, engineering surveyor of Liverpool, acts as resident engineer; and the secretaryship and treasurer'ship are placed in the hands of Mr. J. S. Harmood Banner.

**ST. JOHN AMBULANCE ASSOCIATION.**—A public meeting was held last week in the Shetland Islands to inaugurate the formation of ambulance classes. The Hon. John Dundas, Lord Lieutenant, was appointed president, and an address was delivered by Mr. Samuel Osborn, F.R.C.S., of St. Thomas's Hospital, who attended as a deputation from the St. John Ambulance Association. Fifty-two of the fishermen, naval reserve, &c., at once put down their names for instruction.

**PRESENTATIONS.**—On Friday, the 15th inst., J. Dysart McCaw, Esq., F.R.C.S. Ed., of Portglenone, Belfast, was presented by his neighbours and patients with an illuminated address, a horse, Stanhope gig, harness, saddle, and bridle, as a mark of their confidence in him as a medical practitioner, and their esteem and regard for him as a personal friend.—Mr. Harper, L.R.C.P.L., M.R.C.S., J.P., mayor of Barnstaple, has received during his term of office two testimonials. On June 24th last he was presented by his many friends and patients with a silver dinner service of the value of £120; and on Wednesday, September 13th the town council presented him with a handsome silver salver of the value of £50, in commemoration of the birth of a daughter during his mayoralty. This is not the first presentation of the kind he has received, for when he was mayor in 1874-75 the traditional silver cradle was presented to him to commemorate the birth of a son.

**THE ROYAL HOSPITAL FOR CHILDREN AND WOMEN.**—H.R.H. the Princess of Wales, with her three daughters, the Princesses Louise, Victoria, and Maud, accompanied by the Queen of Greece, and attended by Miss Knollys and Mdlle. Colocotroni, paid a strictly private visit to this hospital on August 15th. Each ward was closely inspected, and every patient's case fully gone into and described by the resident medical officer, Mr. J. Frederick Briscoe. Besides inspecting the wards and roof of the building, their Royal Highnesses descended to the out-patient department, and some of the Royal party examined the kitchen. This is the second occasion this year on which the Princess has paid a visit to this hospital. Her Royal Highness has expressed much satisfaction with both visits. The last one was on June 25th, and the Royal lady was joined by her three daughters, the Princesses Louise, Victoria, and Maud, who distributed fruit and flowers. The Princess of Wales seems to take deep interest in all medical matters, and is well informed thereon. The Royal party remained one hour and a quarter.

**WESTERN INFIRMARY, GLASGOW.**—The information given below concerning this institution was inadvertently omitted from our issue of the 9th inst. Number of beds 380. Besides the ordinary medical and surgical wards, there are special wards for skin diseases and diseases of women. There are four medical assistants and four surgical assistants, who hold office for six months. No fee is charged for these appointments. Non-resident clinical clerks, dressers, &c., are appointed from among the students. Visiting Physicians: Drs. W. T. Gairdner, T. McCall Anderson, James Finlayson, and Gavin P. Tennent. Visiting Surgeons: Drs. G. H. B. Macleod, George Buchanan, Alexander Patterson, and H. C. Cameron. Physician for Diseases of Women and Consulting Physician-Accoucheur: Dr. William Leishman. Out-door Physicians-Accoucheur: Drs. Robert Kirk, W. L. Reid, and Murdoch Cameron. Dispensary Physicians: Drs. Jos. Coats, D. C. M'Vail, and Samson Gemmell. Extra Dispensary Physician: Dr. William G. Dunn. Dispensary Surgeons: Drs. James G. Lyon, D. Neilson Knox, and James Christie. Extra Dispensary Surgeon: Dr. J. C. Renton. Dispensary Surgeon for Diseases of the Ear: Dr. Thomas Barr. Dental Surgeon: Mr. James Rankin, Brownlie. Pathologist: Dr. Joseph Coats. Pathological Chemist: J. L. Silver, M.B. Superintendent: Dr. John Alexander. Secretary: Henry Johnston.—Fees: First year, £10 10s; second year, £10 10s. Hospital attendance and clinical instruction for six months, £7 7s.; three months, £4 4s. Any student who holds a perpetual ticket for another hospital where the fee is not less than the above may join this hospital for the practice only at the following rates: One year, £3 3s.; six months, £2 2s. The fees for clinical instruction in such cases, which are £3 3s. for a six months' course, are paid separately.

## Medical Appointments.

*Intimations for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning at the latest.*

**BAINES, A. H.,** L.R.C.P.Lond., M.R.C.S., has been appointed an Honorary Medical Officer to the Southport Infirmary, vice C. H. Smith, L.K.Q.C.P.I., resigned.

**BLORE, ISAAC,** M.R.C.S., has been appointed Resident Medical Officer to the Netherfield Hospital for Infectious Diseases, Liverpool, vice Hope, resigned.

**BRANTHWAITE, HARRISON,** F.R.C.S. Ed., L.S.A. Lond., has been appointed Medical Officer of Health for the Willesden Urban Sanitary District, vice Thomas, resigned.

**CHITTENDEN, T. HILLIER,** M.R.C.S., has been appointed House-Surgeon to St. Mark's Hospital, City-road, vice Mr. Charles J. Ogle, whose term of office has expired.

**CREW, WILLIAM THOMAS,** F.R.C.S. Eng., L.R.C.P.Lond., L.S.A. Lond., has been appointed Assistant Medical Officer to the Brownlow-hill Workhouse, Liverpool Parish.

**DENHAM, THOMAS REID,** M.D., M.Ch.Q.U.I., has been appointed Medical Officer for the Ireby District of the Wigton Union.

**DOBSON, JOSEPH,** M.R.C.S., L.S.A. Lond., has been appointed Medical Officer and Public Vaccinator for the Headingley-cum-Burley District of the Leeds Union, vice C. Jack, M.D., resigned.

**DUMAT, H. ALYMER,** M.B., C.M. Ed., has been appointed House-Surgeon to the Weston-super-Mare Hospital, vice Ozanne, resigned.

**EVANS, THOMAS GEORGE CANN,** M.R.C.S., has been appointed Medical Officer to the East Budleigh District, St. Thomas's Union.

**EVANS, WILLIAM,** L.R.C.P. Ed., M.R.C.S., has been appointed Medical Officer of Health for the Anglesey and Holyhead Rural, and Beaumaris and Holyhead Urban, Sanitary Districts.

**FARNELL, H. DAWSON,** M.R.C.S., L.S.A. Lond., has been appointed Medical Officer to the Workhouse of the Eastbourne Union, vice Colgate, resigned.

**LOW, ALEX. BRUCE,** M.B., M.Ch. Ed., has been appointed Medical Officer for the Workhouse, Sunderland Union, vice Crossby, deceased.

**MCCLURE, HENRY,** M.D., M.Ch.Q.U.I., has been appointed Medical Officer for the Queen Camel District of the Wincanton Union.

**RAND, R. FRANK,** M.B., C.M. Ed., has been appointed House-Surgeon to the Oldham Infirmary, vice Dr. Harkness, resigned.

**RICHARDSON, WILLIAM,** L.R.C.P. Ed., L.R.C.S. Ed., has been appointed Medical Officer to the Workhouse, Reading Union.

**SCOU GAL, EDW. FOWLER,** M.B., C.M., L.R.C.S. Ed., has been appointed Medical Officer of Health for the combined Austonley, Cartworth, Fulstone, Hepworth, Henley, Holme, Netherthong, Scholes, Upperthong, and Wooddale Urban Sanitary Districts, vice Winpenny, whose appointment has expired.

**WOODCOCK, R. FRASER,** L.R.C.P.L., M.R.C.S., has been appointed Surgeon to the Police of the Borough of Wigan, vice Unwin, resigned.

## Births, Marriages, and Deaths.

### BIRTHS.

**ANDERSON.**—On the 26th July last, at Mhow, Central India, the wife of Surgeon-Major A. Anderson, Army Medical Department, of a daughter.

**SAUL.**—On the 13th inst., at the house of her brother-in-law, Major E. W. Stokes, Lancaster, the wife of W. Wingate Saul, M.D., of a daughter.

**THURSTAN.**—On the 13th inst., at Tunbridge Wells, the wife of E. Paget Thurstan, M.D., B.A. Cantab., of a son.

**TURTON.**—On the 14th inst., at Ashfield-terrace, Heckmondwike, Yorks, the wife of James Turton, M.R.C.S.E., of a daughter.

[ERRATUM.—We are asked to state that the birth announcement under the heading "BARR," published last week, is without foundation.]

### MARRIAGES.

**BARTON-SCOTT.**—On the 16th inst., at St. Peter's, Bayswater, James E. Barton, M.R.C.S., of Brookwood, Surrey, to Ida, widow of the late T. C. Scott, Esq., and daughter of Robert Clark, Esq., of Chepstow Villas, Bayswater.

**BUCHANAN-BINGHAM.**—On the 14th inst., at St. Luke's, Westbourne-park, Arthur Buchanan, M.D. Lond., of High-street, Chatham, to Constance Eliza Maud, second daughter of the late John Bingham, Esq.

**EDWARDS-BARNETT.**—On the 24th ult., at the Priory Church, Leominster, Octavius Edwards, L.R.C.P. Lond., M.R.C.S., of South-street, Leominster, to Laura, eldest daughter of Samuel Barnett, J.P., Surgeon, of The Brook House, Leominster.

**MORRIS-SHIELL.**—On the 14th inst., at the Parish Church, Chester-le-Street, co. Durham, Walter Cameron Morris, M.B., of Chester-le-Street, to Florence Maud, second daughter of the late W. R. Shiell, M.R.C.S., of Chester-le-Street.

**ROBERTS-THOMSON-HULL.**—On the 14th inst., at the Parish Church, Hazelwood, John Roberts-Thomson, M.D., F.R.C.P., of Dunedin, Bournemouth, to Mary Frances Rowe (Rona) Hull, second daughter of the late William Winstanley Hull, Esq., of The Knowle, Hazelwood, Derbyshire.

**THEOBALDS-WOOSNAM.**—On the 6th inst., at Christ Church, Weston-super-Mare, Surgeon-General J. R. Theobalds (Retired List), Madras Army, to Esther (Etty), second daughter of the late Major-General J. B. Woosnam, of the Bombay Horse Artillery.

### DEATHS.

**ALDERSON.**—On the 13th inst., at his residence, Berkeley-square, Sir James Alderson, M.A., M.D., F.R.S., Physician Extraordinary to the Queen, and formerly President of the Royal College of Physicians, aged 87.

**CAREY.**—On the 25th May, at Wellington, New Zealand, Langer Carey, M.D., late Surgeon-Major, Royal Artillery and 101st Fusiliers, second son of the late Dr. Langer Carey, of Churchfield, Newport, co. Tipperary.

**HARRIS.**—On the 16th inst., at The Avenue, Blackheath, Surgeon Major Worsley Poulett Harris, M.D., aged 51.

**LEWIS.**—On the 8th inst., at Whitby, Yorkshire, Waller Augustus Lewis, M.D., Chief Medical Officer of Her Majesty's Post Office, Gordon-square, London.

*N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

## Notes, Short Comments, and Answers to Correspondents.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.*

*Lectures, original articles, and reports should be written on one side only of the paper.*

*We cannot prescribe, or recommend practitioners.*

*Local papers containing reports or news-paragraphs should be marked.*

*All communications relating to the editorial business of the journal must be addressed "To the Editor."*

*Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."*

### MEDICAL OPPOSITION TO IMPROVED REMUNERATION TO MEDICAL MEN.

A CORRESPONDENT directs our attention to a long letter in the *Croydon Guardian*, in which Dr. J. H. Shorthouse argues at great length against the request of Dr. Barnes for an increase of salary, as Medical Officer of the Croydon Union, on the ground that he had held the appointment for nine years at the same salary, but with a great increase in the population and the work. This seems a most reasonable ground on which to base such a request. Dr. Shorthouse remarks Dr. Barnes says nothing of the amount of extra fees which he receives in addition to his salary. But he in nowise shows that this is any reason for not paying him an increase of salary for increased ordinary work. Moreover, Dr. Shorthouse seems to imply that Dr. Barnes' extras are increased by an unnecessarily frequent use of instruments. If Dr. Shorthouse really has such an opinion of Dr. Barnes, he ought to make it the subject of a direct charge at the Board. He ought to go further, and ask for the dismissal of a medical officer whom he thinks capable of such conduct. There is nothing more certain than that professional opinion is in favour of a more frequent use of instruments for shortening labour, and that there are the gravest reasons for not leaving lingering labours to take their own course. But it is greatly to be regretted that a medical guardian should raise such questions in newspapers to the prejudice of a professional brother. Most medical guardians, especially when the vote went against the application of a medical servant, even if they approved it, would have been thankful for a reasonable excuse for taking no part in the discussion.

Mr. W. Davis.—We are unable to recommend the appliance.

H. W. Larkin, M.D.—There are homeopaths and homeopaths.

Mr. Underhill.—The error is corrected in a note published in another column.

### GONORRHOEA.

*To the Editor of THE LANCET.*

SIR,—I trust you will find space for the following remarks in your valuable journal.

Gonorrhoea is such a common and important disease that we must all feel glad that attention is at last being directed to it. The results are often so disastrous and the complications so many that it is high time we tried to obtain some more definite cure than we have at present at command. I find by reference to notes and inquiries amongst other medical men that 75 per cent. of adult males have had it once; 40 per cent., twice; 15 per cent., three or more times. I find that the average duration is about nine months, varying from eight days to four years. No two medical men treat their cases in the same way, but most of them agree that the duration of the disease is long, and the treatment very unsatisfactory. The disease seems to be greatly on the increase, and the older practitioners say that it is becoming more virulent. Could not some inquiry be made into the whole theory and treatment of this dangerous disease? If the treatment so strongly advocated by "M.R.C.S. Eng." is found to be satisfactory, the thanks of the profession will be due to him for bringing under its notice so valuable a remedy. In conclusion, I should like to ask "M.R.C.S. Eng." to give fuller particulars, so that a fair trial may be given.

I remain, Sir, yours, &c.,

Sept. 18th, 1882.

C. H. W.

P.S.—While on the subject, I should like to ask whether gleet is contagious or not?

### WOOD PAVEMENT.

PROFESSOR O. W. WIGHT, Health Officer of Detroit, U.S.A., in a report to the City Council on the healthiness of wooden pavement, and quoted in the *Sanitary Engineer* (New York), advances several objections against that description of road paving. "The blocks, laid endwise," says the Professor, "not only absorb water, which dissolves out the albuminoid matter that acts as a putrefactive leaven, but also absorb an infusion of horse manure and a great quantity of horse urine dropped in the street. The lower ends of the blocks, resting on boards, clay, or sand, soon become covered with an abundant fungoid growth. Thoroughly saturated with albuminous extract and the excreta of animals in a liquid, putrescible form, these wooden block pavements undergo a decomposition in the warm season and add to the unwholesomeness of the city. The streets, in fact, might as well be covered a foot deep with rotting, barnyard manure, so far as unwholesomeness is concerned. Moreover, the interstices between the blocks and the perforations of decay allow the foul liquids of the surface to flow through, super-saturating the earth beneath, and constantly adding to the putrefying mass."

Mr. E. Houghton, B.A., M.D.—When the genius foreshadowed in our correspondent's letter arises and formulates a comprehensive generalisation that shall include all therapeutics under one head, or a very few heads, it will be absurd to fight against the necessity for a designation of such a special mode of treatment, and ungenerous to withhold from the genius unbounded respect. Meantime all actual pretensions to such discoveries are worthy of nothing but repudiation by men and societies which respect the fair fame of scientific medicine.

### "VENESECTION: WHY IS IT SO RARELY PRACTISED?"

*To the Editor of THE LANCET.*

SIR,—In your issue of to-day, "Bothered" concludes that venesection is so rarely practised because the otherwise would-be operator has never seen a vein opened. It is devoutly to be hoped for the credit of our profession that this explanation is purely imaginary. Surely no medical man would for a moment hesitate to relieve pain by giving a hypodermic injection, or perhaps save life by a stimulant enema, simply because he did not "feel that he could do it nicely." Would "Bothered" himself, for example, neglect to pass a catheter for urgent retention of urine in a woman solely because perchance he had "never witnessed the actual operation." Surely not. Yet it would be easier far to "bungle" over that than over the section of a subcutaneous vein; and I contend that by that simple section we may relieve the most agonising pain, and restore the moribund to life and vigour. I am constrained to believe that the present most deplorable disuse of venesection arises partly from a lack of exact knowledge of its usefulness and partly from a distrustful remembrance of its former abuse. Our grandfathers were bled to death and salivated to toothlessness, and the reaction from empiricism banished for a time both blue pill and bleeding. I fervently hope and believe that even as mercury is now used in a rational manner with immense benefit, so the great and true value of bloodletting will soon be recognised also, for I imagine that venesection, discreetly employed, will be found very valuable in many diseases. That it is a most potent remedy in appropriate cases of chest affections I endeavoured lately to point out in your columns, and that our present neglect therefore of this powerful weapon is most disastrous to our patients, humiliating to our art, and oftentimes unfortunate for ourselves, I am most firmly convinced.

I am, Sir, yours faithfully,

West-street, Finsbury-circus, E.C.,  
Sept. 16th, 1882.

BEDFORD FENWICK.

*To the Editor of THE LANCET.*

SIR,—The statement of your correspondent, "Bothered," that "the actual operation of opening a vein is never witnessed by the student," should not remain unchallenged. It is only three years since I left Guy's. During my six years' studentship at that hospital I frequently saw venesection performed, and I bled several patients myself while holding the appointments of dresser and clinical assistant. Similar is the experience of every Guy's man who has taken advantage of the opportunities offered him by his hospital.

I am, Sir, yours faithfully,

Sept. 17th, 1882.

NOT BOTHERED.

Nemo.—1. "Legally qualified practitioner" is a correct phrase.—2. Yes.—3. A person registered with a surgical qualification only is not entitled to recover for attendance in other than surgical cases.

### A NEW USE FOR SALICYLATE OF SODA.

*To the Editor of THE LANCET.*

SIR,—In a case of severe chalk gout I applied several different lotions with a view to remove, if possible, the ugly excrescences on the fingers. None of the lotions had the desired effect of altogether removing the deposits, but a lotion of ten grains of salicylate of soda to the ounce was successful in removing small deposits from the ear. The chalky matter was softened, and in four days disappeared, leaving a small scar as its representative.—I am, Sir, yours, &c.,

THEO. M. KENDALL,

B.A. Sydney, N.S.W., L.R.C.P. Ed.

Porteus-road, Maida-hill, Sept. 12th, 1882.

## DISEASES OF MINERS.

THE prevalence of ankylostomiasis amongst the workmen employed in the construction of the St. Gothard tunnel is in part attributed to the fact that this disease is endemic in a great portion of Northern Italy, from which district many of the workmen came. Dr. Fabre, of Commeny (Allier), in his remarks at the Geneva Congress, maintained that any prevalence of this affection amongst miners would in most cases arise from the importation of the germs of the disease, as there is nothing in the nature of a miner's occupation to produce the disease without such a cause. Dr. Fabre considers that the ravages of the malady were aggravated by the poor and insufficient nourishment of the St. Gothard workmen, and by the bad air and noxious gases they breathed, which would have evidently produced anæmia, and thus facilitated the spread of ankylostomiasis.

Mr. John W. Stedman.—In the general view of our correspondent we fully concur, but it is not shown that the practitioner called into consultation did not "hesitate" before acting as he did. We are not prepared to say that a practitioner called into consultation should never afterwards accept the post of family adviser. The freedom of the patient must be considered. But undoubtedly he should do so, if at all, only with regret and reluctance.

## DEVICE FOR ESTIMATING HÆMOGLOBIN.

To the Editor of THE LANCET.

SIR,—The following device for estimating the amount of O. hæmoglobin contained in a small quantity (say five cubic millimetres) of human blood will perhaps be acceptable to some of your readers who, like myself, have to work at a distance from reliable instrument makers, and might induce some of the latter to supply the profession with the necessary apparatus.

The principle of my contrivance is not new, being an application of Preyer's spectral estimates of hæmoglobin solutions and of a tube similar to those employed by Duboscq in his calorimeter, so as to compare successive measurable depths of a blood solution. The novelty, if such there be, consists in the use of a diluted solution of blood obtained from any red-blooded animal as a gauge determining the depth of this solution, that will give one or other of Preyer's O. hæmoglobin spectra, and observing the difference of depth required to obtain the same spectra, after a cell one centimetre deep and filled with one per cent. solution of human blood has been introduced under the gauged animal blood.

I had only at my disposal a small Browning's pocket spectroscope of the simplest pattern. I mounted it as an eye-piece suited to my microscope, and fitted to its distal end, beyond the slit, a hard rubber tube about twelve millimetres in diameter. The lower end of this tube was cut perpendicularly to its axis and closed with a plane glass disc, well cemented around the edges. When this eye-piece is in position and the sliding tube of the microscope is pushed home, the glass plate of the rubber tube touches another glass plate which forms the bottom of a cylindrical vessel standing upon the stage of the microscope. Into this vessel I introduce about fifteen cubic centimetres of a dilute solution of defibrinated blood (the requisite quantity, less than one cubic centimetre, being easily obtained by pricking, for instance, a vein under a chicken's wing), and graduate the solution so that from twenty-five to thirty millimetres of depth are required in order to produce the particular spectrum selected as a type, and the value of which in O. hæmoglobin percentage should be specially determined for each particular instrument. The depth is, of course, measured by the distance between the two glass plates already mentioned, but it can be read off at once provided the sliding tube of the microscope has been ruled on the outside with lines one millimetre apart, and numbered from above downwards. The exact depth that produces the typical spectrum having been noted down, the instrument is ready for immediate use.

A cell formed of a piece of hard rubber syringe, No. 0 (say half centimetre, inner diameter), exactly one centimetre long and cemented upright to a microscope slide, is now filled with a mixture of five cubic millimetres of human blood in 500 (half cubic centimetre) of distilled water, and covered with a thin glass cover, excluding all air-bubbles. This cell is introduced between the stage and the glass bottom of the cylindrical vessel containing the diluted chicken's blood and the typical spectrum again sought for. It will, of course, be found that a lesser depth is now required than before the addition of the centimetre cell with the human blood. The difference between the two depths, divided by the full depth previously noted down, multiplied by the percentage of O. hæmoglobin corresponding to the typical spectrum, and finally multiplied by 100, will be the percentage of hæmoglobin contained in the pure human blood from which the sample was taken.

I am, Sir, yours very truly,

Navana, Cuba, August 7th, 1882.

CHARLES FINLAY, M.D.

## A CORRECTION.

To the Editor of THE LANCET.

SIR,—In the "Mirror" of Sept. 16th you reported a case of lithotomy performed at the Guest Hospital. In the heading it is stated that the stone weighed "three ounces." It should have been "eight ounces."

I am, Sir, yours faithfully,

ROBERT WALFORD (late House-Surgeon).

Stanhope-street, N.W., Sept. 18th, 1882.

## CAUTION TO MEDICAL PRACTITIONERS.

WE are asked to publish the following:—A man about 5 ft. 8½ in. in height, and apparently about thirty-five years of age, has been calling and raising money on the false pretence that he is a doctor from a town in Lancashire, and is in temporary difficulties to take him home, and he will remit the amount immediately on his return." He is very plausible, and is very conversant with the names of persons in Inverness and neighbourhood, also with those of professors and medical practitioners in Aberdeen and Edinburgh.

## "THE CAUSE OR CAUSES OF ACUTE TONSILLITIS."

To the Editor of THE LANCET.

SIR,—It appears to me that in the correspondence on this subject, which has recently appeared in your journal, sufficient notice has not been taken of the fact that the terms quinsy and tonsillitis cover three distinct conditions.

With reference to the case reported by Mr. Boys in THE LANCET of August 26th (which I have only just seen), I am not surprised at salicylate of soda being ineffectual. My experience of the use of that drug leads me to confine its beneficial results to catarrhal tonsillitis—i.e., catarrh of the mucous membrane and crypt follicles. These cases very rarely run on to suppuration. I have never seen a case that was clearly one of simple catarrhal tonsillitis eventuate in suppuration, although I should not like to say they never do so. On the other hand, the true fibrous tonsillitis—that is, inflammation of the gland substance itself—almost invariably suppurates, as does very frequently, though not always, a form of the disease which really affects only the surrounding structures, and which is often accompanied, like the parenchymatous form, by considerable œdema of the palate, uvula, &c. This was the form of the disease in the case I mentioned in your issue of July 29th, during the earlier part of the discussion.

Cases of the two latter classes are very unlikely, so far as I have seen, to be benefited by salicylate of soda; for although, for the sake of observation, I have used it in all cases of tonsillitis, whatever their nature, up to quite recently, I have not found any good result therefrom save in the catarrhal form. I have therefore discontinued its use in the other forms of tonsillitis. But that it is of great value in cutting short the simple catarrhal form I can speak from a repeated personal experience.

I am, Sir, yours faithfully,

KENNETH W. MILLICAN, B.A.

Kington, Warwick, Sept. 18th, 1882.

To the Editor of THE LANCET.

SIR,—Under the above heading, in your issue of the 2nd inst., I noticed a letter from Mr. Grewcock, stating that he has found pulling down the lobules of the ears relieves painful deglutition, and can from personal experience bear testimony to the efficacy of the principle which he recommends—viz., closure of the external auditory meatus; although the plan suggested in my case, and which I now always recommend, produces that effect in a different manner.

When a boy, I had a very severe attack of diphtheria, and the following method of relieving theodynophagia was suggested by a servant who had suffered from the same disease. It is this. To stand as nearly as possible behind the patient, who should be in bed or seated in a chair, and place the palm of each hand over an ear, then make very firm pressure. I always preferred the servant before mentioned to press my ears whilst I was taking nourishment, because she did so more firmly than anyone else; my friends either feared that the force they were using would injure me, or else had not the strength.

I am, Sir, yours truly,

T. MARK HOVELL.

Mansfield-street, Cavendish-square, Sept. 2nd, 1882.

Mr. W. R. Parry Jones.—We are not aware of the existence of an institution of the kind mentioned.

## LECTURES ON DISEASES OF WOMEN AND CHILDREN.

To the Editor of THE LANCET.

SIR,—A want often exists of which we are not conscious until circumstances force it upon our notice. Such is my case. Having completed my necessary residence for the M.B. of Edinburgh, I find I require a three months' systematic course of lectures on diseases of women and children. I have sought in vain to meet with such a course in London.

As other students may be placed in a like predicament, I would ask—would it not be well that at some of the hospitals which take the lead in things medical a systematic course on the above subjects should be instituted? Without this it certainly strikes me our metropolitan schools are incomplete.—I am, Sir, your obedient servant,

London, Sept 20th, 1882.

FOURTH YEAR'S MAN.

## THE LATE SURGEON-MAJOR GEORGE SHAW, A.M.D.: MENTION IN DESPATCHES.

To the Editor of THE LANCET.

SIR,—I find no entry whatever in General Graham's despatch about the affair at Kassasin Lock with reference to the death of our brother officer, George Shaw, who perished there. These official neglects are lamentable.

I am, Sir, yours, &c.,

Sept. 20th, 1882.

ONE OF THE A.M.D.

## MEDICAL ADVERTISING IN SOMERSET EAST, SOUTH AFRICA.

THE circular of T. E. Butler is in very bad form, and the profession in South Africa should take means to discourage and condemn such advertising.

## "RIDER'S SPRAIN."

To the Editor of THE LANCET.

SIR,—Observing letters on the above in THE LANCET of July 29th and August 5th, I venture, through your columns, to recommend sufferers from the injury to give a trial to "Huxley's support for injury to the large muscle of the thigh," advertised in THE LANCET of August 5th. I first injured the muscle at polo about four years ago, and suffered off and on from the injury for three years, at times having to give up riding altogether for three weeks or so. The bandage roller ordinarily used in the hunting field gave a certain amount of support, but even with it anything like a hard game of polo made riding the following day almost an impossibility. Last year my attention was drawn to the advertisement of Mr. Huxley, 12, Old Cavendish-street, W., and I send for one of his supports. Within a week or two after commencing to wear it, my leg was, to all intents and purposes, well, and I have had no return of the injury, though I have played polo regularly during the last twelve months. I still wear the support at polo as a precautionary measure, but after using it for a month I was able to discard it for ordinary riding. I cannot too strongly recommend a trial of the support to any sufferers from the injury.—I remain, Sir, yours faithfully,

R. CALDECOTT,

East Indies, August 26th, 1882. Surg.-Maj., Central India Horse.

Mr. James Richards ought to communicate the facts to the medical officer of health.

## THE REEF-KNOT v. GRANNY.

To the Editor of THE LANCET.

SIR,—In answer to "F. A. P.," let me point out that anyone may be sure to tie a reef-knot. Even blindfolded or subcutaneously, good men sometimes fall in so doing, but it can always be ensured by remembering one little incident—viz., after making the first twist or turn, complete the knot by placing that end of the string which is anterior to the anterior of the other end; it matters not then which end is twisted round the other to complete the knot. Take an example in X:—

Showing first twist, where the end A is anterior; then pass it to the anterior of B.

Showing the end A posterior; then pass or cross it behind B, and make your final or second twist.

The end A is anterior. Now, if this end A is carried across in front of B, it matters not whether A or B continue the final turn. Y shows the ends twisted opposite to X; here the end A being posterior, pass it to the back of B, and make your second turn.

I am, Sir, yours faithfully,

Twyford, Sept 2nd, 1882.

J. BATTEN COUMBE, M.D.

M.R.C.S. Eng.—There is nothing in the nature of such a case making it necessary for the practitioner to desist from obstetric practice.

Mr. Henry Morris.—At an early date.

## IODOFORM.

To the Editor of THE LANCET.

SIR,—Perhaps some of your readers will favour me with their experience of the use of Iodoform. Can urethral pessaries, composed of five grains of Iodoform and made up with theobroma and eucalyptus oil, be used with safety in the male urethra every four hours for several days? If not, what would be the result and symptoms likely to follow?

I am, Sir, yours truly,

Sept. 19th, 1882.

YOUNG PRACTITIONER.

Subscriber.—The book may no doubt be obtained through Messrs. Churchill, New Burlington-street.

## DAY NURSERIES.

To the Editor of THE LANCET.

SIR,—Would you kindly allow me, through your journal, to ask if any of your subscribers could inform me of any crèche or day nursery for children under a year old? We are desirous of starting a similar institution here, and are anxious to learn particulars of working expenses, &c.

I am, Sir, yours very truly,

Motra House, Arnold, Sept. 19th, 1882.

R. S. WALLACE.

## GYNECOLOGICAL TABLE.

Dr. Monckton (Maldstone) asks to be informed where he can inspect a simple but effective gynecological table for hospital use? What makers supply such an affair? Costly complexities objected to.

## CHRONIC URETHRAL INFLAMMATION.

To the Editor of THE LANCET.

SIR,—Will you please give insertion to the following peculiar case:—A gentleman aged forty, married, of active habits, and otherwise enjoying good health, came to me two months since complaining of burning scalding pains along the urethral track, occurring several times a day, some days very slightly so, but worse at night in bed. This has been going on since last December. He has had no discharge. There is no stricture. The urine is perfectly normal; he passes it only three times a day, and his bowels act regularly. The glands along the urethral track are perceptibly enlarged, and almost constantly an inflamed ring can be perceived around the urethral orifice. The urethra is so sensitive and inflamed that I could not succeed in passing a sound. The patient objects to an anæsthetic. Micturition does not add to the pain. He has never had syphilis, but had gonorrhœa about three years ago and previously. He has consulted two or three hospital surgeons in London, who prescribed laxatives, without effect. I do not consider he is the subject of stone or of enlarged prostate. He lives very moderately. I prescribed the mineral acids and vegetable tonics. They have had no effect. I now apply to the profession, through your courtesy, to inform me what is the treatment to adopt.

I am, Sir, yours obediently,

Sept. 18th, 1882.

A YOUNG SURGEON.

Sufferer should consult a legally qualified surgeon, and avoid advertising quacks.

G. P has not enclosed his card.

## DISLOCATION OF THE SHOULDER, AND ITS REDUCTION BY AN EASY METHOD.

To the Editor of THE LANCET.

SIR,—The following particulars seem to merit attention not less on account of certain peculiarities which the *modus operandi* presents than from the remarkable facility with which reduction was effected.

Mr. W.—, a middle-aged gentleman, consulted me respecting an injury to the shoulder caused by a fall. On examination, I found immobility of the joint, projection of the elbow, flattening of the deltoid, and the characteristic depression beneath the acromion. Having satisfied myself as to the nature of the accident, the patient was placed laterally upon a chair, the back of which was firmly held by an assistant, while gradual extension of the displaced limb was made above it by another. This proceeding was continued for a few seconds—until, in fact, the opposing muscles were sufficiently relaxed, when, by a simple manipulation, the head of the humerus was gently elevated into its proper position. The usual adjustment of the arm to the side completed the operation, and the case has progressed favourably ever since.

I am, Sir, yours obediently,

Leeds, Sept. 6th, 1882.

CLARENCE FOSTER.

Enquirer is most fully justified. He should consult the best solicitor he can find.

## SUDDEN DEATH THREE WEEKS AFTER DIPHTHERIA.

To the Editor of THE LANCET.

SIR,—On Sunday, August 6th, 1882, a child aged ten years was brought to my surgery by her father, and complained of sore throat. I examined the throat, and found extensive exudation of a diphtheritic type covering the whole of the fauces and base of the tongue. I applied nitrate of silver, and gave large doses of chlorate of potash and tincture of perchloride of iron every two hours (with three grains of calomel at once), and recommended good diet, warm vinegar poultices to the throat, with moist atmosphere from the steam-kettle. On August 7th I saw the child early in the morning, and found her blue. I therefore at once performed tracheotomy, the good result of which was immediate; the wound healed, and she, to all appearance, got perfectly well. Three weeks after, while at dinner, she suddenly fell and was taken up dead. Can any of your readers give me an explanation of the immediate cause of death? Sir W. Gull told me (his late pupil) that "we often get some heart mischief after diphtheria, but cannot tell what the cause is."

I am, Sir, yours, &c.,

Brabourne, August 29th, 1882.

ALFRED CHARLTON.

A Constant Subscriber might consult Dr. Hardwicke's book on Medical Education and Practice Abroad.

## AN APPEAL.

To the Editor of THE LANCET.

SIR,—Will you allow us to appeal to the profession on behalf of the family of the late Dr. Thompson, of Beverley. This gentleman died, after a short illness, from inflammation of the lungs, brought on by exposure while in the performance of his duties, leaving a wife and six daughters (the youngest about twelve months old) almost destitute. We shall be glad to receive any subscriptions that may be sent.

We are, Sir, your obedient servants,

HENRY WALKER, M.D.,

E. D. TOMLINSON, Brigade Surgeon half-pay.

Beverley, Sept. 18th, 1882.

## "A CASE FOR HELP."

THE following amounts have been received at THE LANCET Office on behalf of the above:—Mr. Shaw, Hunslet, £2 2s.; A Well Wisher, 10s.; Mr. J. C. Moore, Ongar, 10s.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Professor Bentley, London; Mr. Scott, Brighton; Mr. W. Wallis, Mr. Pratt, Belfast; Dr. Gordon Holmes, London; Dr. Weatherby, Portishead; Surgeon-Major Caldecott, Augur; Mr. Walford, London; Surgeon-Major O'Farrell, Neesmuch; Mr. Clifford; Mr. Millican, Kington; Mr. Wallace; Mr. Banner, Liverpool; Messrs. Fletcher and Co., Holloway; Dr. Lediard, Carlisle; Messrs. Singer and Co., Coventry; Dr. Wallis, Monmouth; Dr. J. M. Duncan, Galashiels; Mr. Leared, London; Dr. Gillespie, London; Mr. Charlton, Ashton; Dr. Pratt, Appledore; Mr. L. E. Wright, London; Mr. Sannes, Wimbourne; Mr. Duncanson; Mr. Hamilton; Mr. Bulmer, Hereford; Mr. Sugden, Queensland; Dr. Darwin, Didsbury; Mr. J. J. Reynolds, Stoke-by-Clare; Dr. Bedford Fenwick, London; Dr. G. de Courcy Morris, York; Mr. Broadbent, Liverpool; Dr. Sack, Cork; Mr. Plunkett-Johnstone, Darlington; Messrs. Talbot, Liverpool; Dr. Annington, Cambridge; Mr. Winter, Wolverhampton; Dr. Monckton, Maidstone; Dr. Wise, London; Dr. Samuel West, London; Mr. Parry Jones, Ruabon; Dr. Menzies, Cadenabbia; Mr. Cheyne Brady, Veytaux; Mr. Wallers, Blackburn; One who Advocates Exercise in the Pure Air; Ager, Stoke Newington; N. A., Birmingham; T. Vero, Malvern; Subscriber; Young Practitioner; Medicus, Gloucester; A Constant Subscriber; Chandos; M.R.C.S. Eng.; A Young Surgeon; C. H. W.; Trocar; Not Bothered; G. H. E., Sheffield; &c. &c.

LETTERS, each with enclosure, are also acknowledged from—Mr. Benn, Rugby; Mr. Woodman, Bridgewater; Mr. Turner, Norwich; Mr. Ward; Mr. Hancock, London; Mr. Bullivant, Derby; Mr. Forsyth, Birstal; Mr. Watkins, Worcester; Mr. Duncan, Fressingfield; Mr. Ellerton, Middlesboro'; Mr. Roberts, Sheffield; Mr. Watts, London; Mr. Cook, Lowestoft; Dr. Reynolds, Stoke; Messrs. Beal and Co., Brighton; Mr. Turton, Heckmondwike; Mr. Magennis, Lurgan; Miss Bailey, Stirling; Dr. Edwardes, Hounslow; Messrs. Smith and Son, Birmingham; Dr. Dennis, St. Austel; Mr. Coram, Bristol; Mr. J. H. Day, Wigan; Mr. Heelis, Barrow-in-Furness; Mr. Cutler, Rotherham; Mr. Saplin, Blinbrook; Mr. Fords, Drumlithie; Mr. R. F. Shaw, Hunslet; Messrs. Johnson and Co., Southport; Mr. Samuel, Llanelli; Mr. Neame, Birchington-on-Sea; Mr. Holloway, Kidderminster; Mr. Humphreys, Wrexham; Mr. Brown, Malvern; Dr. Williams, Towey; Mr. Morgan, Litchfield; Messrs. Keith and Co., Edinburgh; Messrs. Beddingfield, London; Dr. G. Holmes, Vision; H. M., Bow; Y. Z., Manchester; Medicus, Dromore; M., Hungerford; Registrar, Bath; A Well Wisher; Student, Nottingham; R. H. S.; Eastern Counties; Marlboro'; L.R.C.P., London; Sigma, Bishop Auckland; Medicus, Swansea; G. T.; A. S.; Accident; M. A. Y.; Ozone; A., Notting-hill; Medicus, Seaford; J. E. G., Frampton-on-Severn; L. P., Littlehampton; Idem, Liverpool; Bow; M. D., Cleaton; A. B., West India-road; M. H., North Kensington; Surgeon, Swinton; Medicus, Birmingham; Medicus, Bethnal-green; A. L., Kensington; Omer; Ivy House; Scapula, South Hampstead; R. W. C., Ilkley; Surgeon, Tunbridge Wells; Physician, Northallerton; E. C. H., St. George's-road; H. A. C., Borough; &c., &c.

Scientific Review, Sydney Daily Telegraph, Tewkesbury Register, North Wales Chronicle, Cambridge Chronicle, Hertfordshire Mercury, Wine and Spirit News, Pictorial World, Plumber and Decorator, Queen's Own Gazette, Warehousemen and Drapers' Trade Journal, Chester Guardian, Daily Courier, Port Elizabeth Telegraph, &c., have been received.

## METEOROLOGICAL READINGS.

(Taken daily at 5.30 a.m. by Steward's Instruments.)

THE LANCET OFFICE, Sept. 21st, 1882.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on page 2, which not only affords ready means of finding any notice, but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance. Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed. Advertisements are now received at all Messrs. W. H. Smith and Sons' Railway Bookstalls throughout the United Kingdom, and all other Advertising Agents.

Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher.

Agent for the Advertising Department in France—J. ASTIER, 87, Rue Cassmartin, Paris.

# Lectures ON THE

## MECHANISM OF RESPIRATION IN PHYSIOLOGICAL & PATHOLOGICAL CONDITIONS.

Delivered before the Faculty of Physicians and Surgeons of Glasgow,

By D. C. McVAIL, M.B.,

FELLOW OF THE FACULTY, AND LECTURER ON MEDICINE IN THE GLASGOW WESTERN MEDICAL SCHOOL.

### LECTURE I.—PART II.

THE third of the great physiologists of the seventeenth century who devoted very special attention to the function of respiration was a native of Cornwall—John Mayow, born in 1645. He was a student of All Souls in Oxford and took degrees in Civil Law and Medicine. Regarding the chemistry of respiration, he was far in advance of his time, as in 1674 he published a series of tracts, in one of which he teaches that in the atmosphere there is a special constituent which he calls the nitro-aerial spirit or igno-aerial spirit, that he says is the food of life and flame, and is absorbed by the blood, and that by it in the lungs animal heat is produced. He thus, exactly one hundred years before Priestley, foreshadowed the discovery of oxygen. As regards the mechanism of respiration, his labours are the less of service to science in that, curiously, he seems to have supposed that the ribs in their lowest position were almost at right angles to the spine. He affirms that both sets of intercostals are inspiratory.

The work done by these three distinguished physiologists in the seventeenth century, and the publication of very reliable treatises on anatomy by Diemerbroeck, at Utrecht, in 1672; by Philip Verheyen, at Brussels, in 1693; and by Winslow, at Paris, in 1711, supplied the necessary data for a much more comprehensive inquiry into the mechanism of respiration than had thereto been possible, and in 1727 George Edward Hamberger published his celebrated dissertation on the Mechanism and Genuine Use of Respiration. His work consists of seventy-three propositions, occupying forty-four small quarto pages. So far as I can discover, there are but three copies of the book in this country—the one I have seen is that in the library of the Royal Medico-Chirurgical Society of London,—which is not the original edition, but a reprint of later date. In illustration of his views he gives this diagram (Fig. 3)

FIG. 3.

that has been used in Germany in most disquisitions on the movements of the chest since his time. The fixed pillar A B he assumed to represent the spine, and the levers A C and B D the ribs, with axes movable round A and B, and separated and yet connected at their anterior extremities by the rigid body C D, and movable round the axes C and D. He represents the ribs, A C and B D, as of equal lengths, and

No. 3063.

so the structure is a parallelogram. Assuming that in expiration the ribs are so inclined to the spine that the angle formed by the spine and the lower border of each is less than a right angle, he reasons regarding the effect of the elevation of these in the following manner in proposition 21:—Placing the levers obliquely downwards as in A C and B D, and elevating them so that A B with B F will contain a right angle, it is plain: 1st. That the distance B C is less than B F. 2nd. With B C the distance of the line C D from A B before elevation, the distance of the line G F after elevation of the levers A C and B D is greater from the fixed fulcrum A B than before elevation. 3rd. With the parallelograms A F and A D having the same base A B, but with different altitudes, A F is greater in area than A D. 4th. If from B is led to A C a perpendicular B B', which is the distance between the levers A C and B D, this perpendicular is less than the line A B, which is the distance between the lines A G and B F; in one word, the elevated levers have a greater distance between them than when not elevated. Conversely, in proposition 22 he reasons that by the descent of the levers from the position of right angles:—1st, the body, G F, comes nearer to A B; 2nd, the whole parallelogram becomes less; 3rd, the levers approach nearer to one another. The truth of these propositions of Hamberger with regard to parallelograms is of course indisputable, and in so far as the thoracic walls can be regarded as constructed on the parallelogrammic type they apply to it in its various movements.

Very curiously, in this country the book by Hamberger would seem to have received but little attention; and this

FIG. 4.

is the more wonderful that certain other parts of it led in Germany to a very warm discussion between him and Haller, a discussion that Hamberger afterwards printed in full. So little, indeed, was known in England of what Hamberger had done, that in the first quarter of the present century the late Dr. John Hutchinson did it all over again, and for four years after he had done it did not know that he had been anticipated by nearly a century in his work; and it is from Hutchinson, and not from Hamberger, that our home anatomists and physiologists have for the most part received their ideas on the subject. In all essential particulars the teaching of the two men is the same, only the language of the older of them is by far the more elegant and precise. They both assume that the movements of the chest are comparable to those possible to parallelograms, and deduce conclusions accordingly, and both constructed a movable machine to illustrate this, such as I show you. (Fig. 4.) But I must proceed to show that in many particulars this arrangement is not a correct representation of the thoracic mechanism, and that some conclusions founded on the supposed similarity are entirely wrong. To make this clear let me point out the range of movements possible to this parallel structure (Fig. 4), and the causes that confine these movements within certain limits—for a limit there is to the movement both in an upward and downward direction,—and the whole movement possible to each lever in the arrangement is less than half a circle—less than 180°. Let A in

N

Fig. 5 be a fixed pillar, and the lever C B attached to it by a freely movable pivot at C. It is self evident that the lever can be moved through the whole circle 1, 2, 3, and in

FIG. 5.

either direction. It has a range of 360°. In Fig. 6 in addition to the lever, C B, let there be a second lever, E D, attached to the same pillar, A, and to the same side of it,

FIG. 6.

and the point of attachment of E D to be at a less distance from the point of attachment of C B than the length of C B, and let E D be of the same length as C B, it is manifest

FIG. 7.

FIG. 8.

that the lever C B can move through the circle until it comes in contact with the parts of lever E D about the pivot E, by which it is prevented from entering the sector B B'. In like manner, the parts of lever C B about the pivot C render it impossible for E D to enter a similar segment at the top of the circle that would be described by E D. Each lever if moved independently of the other can travel through the greater part

of a circle, being precluded from entering only a very small sector. But placing the levers on the same side of the pillar A as in Fig. 7, let us suppose that from some cause they cannot be moved independently of one another, that the motive power can act only *simultaneously on both*, and also that it acts on both *uniformly as regards direction*, then must the range of each be less than half a circle, for when C B (Fig. 8) is brought to a standstill by the parts about E, E D also will cease to move; and so too when E D is brought to rest by the parts about C, C B must stand still as well. But a rigid rod, L, attached to the extremities of the parallel levers C B and E D, as in Fig. 9, must necessarily cause any force acting on either lever, or on both levers, to act on both *simultaneously*, and also *uniformly as regards direction*,

FIG. 9.

FIG. 10.

FIG. 11.

for C B cannot now be moved without pulling E D with it, and so must stop when E D can go no further, as happens when it comes against C (Fig. 8); and similarly E D cannot travel without C B, and must stop when C B stops, which is when it comes against E (Fig. 8). For these reasons the range of movement of the mechanical arrangement of Hamberger (Fig. 4) is limited for each and all of the levers to less than 180°. But, as I have already said, this parallel structure does not accurately represent the thoracic mechanism, and the departure of the thoracic from the parallel type introduces many most important modifications as to the possible and actual movements of respiration. In two most important particulars the thorax departs from the parallel arrangement of Hamberger; the spine is not a straight column, but is *curved*; and the sternum is not parallel to the general direction of the spine, but is inclined to it at a very considerable angle.

That the dorsal region of the spine, to which the ribs

are articulated, is curved, with the concavity looking forwards, everyone is aware; but it does not appear to have been noted that the line which would join or intersect the costo-vertebral articulations is always much more curved than the general contour of the spine itself, forming a segment of a somewhat smaller circle than the general contour of the dorsal curve. Yet such is most decidedly the case. Fig. 10 shows the curve of the line of the costo-vertebral articulations of a thorax that in the fresh condition I embedded in plaster of Paris, and when quite dry and hard was sawn on one side in the line of the joints of the heads of the ribs with the spine. In Fig. 11 is shown the costo-vertebral curve from a cast of the cavity of the thorax taken from a fresh subject, and Fig. 12 shows the curve in a cast taken from a frozen subject. The curving you see is in all these well marked, and thus the thoracic structure departs in a most important respect from Hamberger's parallel machine. The second point, in which it diverges from the type of the mechanical arrangement of Hamberger, is that the sternum is not parallel to the general direction of the spinal column, but is very considerably inclined to it. That the sternum is inclined to the spine no one will deny, but not many have realised how very marked the angle of inclination really is. Fig. 12 represents accurately the mutual inclination of di-

FIG. 12.

rections of the spine and sternum in a cast from a frozen subject. And so far are the spinal and sternal lines from being parallel to one another, that if produced upwards they would at no great distance intersect. Very far, then, does this structure depart from the parallel type, and thus we are led to inquire what modifications as regards movement are introduced by the departure of the thorax from the parallel type, modifications of movement, I mean, as compared with those of Hamberger's machine.

First, I will consider the effect of the inclined position of the sternum to the spine. In this model (Fig. 13) I have, as in Hamberger's machine, an upright pillar, A representing the spinal column, a wooden rod, L for the sternum, and this inclined to the spine, and the rib levers CB and ED parallel to one another, and so placed that the inferior border of each forms with the spine an angle that is less than a right angle. (In the meantime will the reader kindly disregard the two lower rib levers G F and K H.) If now I elevate the sternum the upper lever CB comes to be at right angles to the spine, but when it is exactly at right angles to the spine the second lever ED has not yet attained to that position. Still further elevation, however, will bring ED to right angles with the spine, as is shown in the diagram, where ED has become ED'. But when the second

lever has attained to right angles the first has passed that phase, as shown by the line CB' in the figure. Here, then, we have a most important difference between this arrangement and Hamberger's, for with a parallelogram both levers necessarily come to be at right angles simultaneously. Hamberger justly reasoned that when his rib levers in his parallel machine came to be at right angles to the spine that the greatest area had been attained. But in the arrangement shown in Fig. 13, as both levers cannot simultaneously be perpendicular to the spine, we have to note in the case of the trapezium C, E, D', B', in what position of elevation the greatest area is attained. Geometry answers that the area is greater when the longer of the two levers is at right angles to the spine than when the shorter is in that position. Therefore, the thoracic arrangement being not parallel but approaching in form to a trapezoid or trapezium, we must alter the teaching of Hamberger and Hutchinson to this—that any intercostal space will have its greatest area when the larger of the two ribs bounding it forms a right angle with the spine. But now suppose the sternum to be once more depressed to its original position L, with CB and ED again parallel to each other, and let two more levers GF and KH be added, both of them parallel to the higher levers. We have now three trapezoidal spaces and obviously

FIG. 13.

they cannot all at the same time be at the greatest possible area. For when the upper space has the longer of its two rib levers at right angles to the spine, the greatest sides of the second and third spaces will not yet have attained to such position, and when by continuing to elevate the larger of the rib levers of the third space reaches this position, those of the upper two spaces will have passed that position, and both those areas will be diminishing. But the gain of area of the lower space more than makes up for the loss of area in the upper spaces, and so the contained area of the whole figure is greatest when the largest of the four levers is perpendicular to the spine. But now, with a model having its parts arranged as in the depressed position shown in Fig. 13, I will endeavour to elevate the sternum from the position B L until H K is perpendicular to A N,—but I cannot. Elevation to such

an extent is impossible. And if I seek to depress the sternum below the position B L, I find that the range of movement downwards is also extremely limited. And if I substitute for the straight spine at N, a spine having the natural curve of the vertebral column of which I have already spoken (Figs. 10 and 11), the difficulty of movement becomes still greater—in fact the apparatus is well nigh immovable. Here there is a most important difference between the arrangement of Hamberger and Hutchinson—having parallel spine and sternum, and parallel levers—and the arrangement having the true spinal curvature, and the sternum inclined to the spine. For Hamberger's machine

FIG. 14.

(Fig. 4) permits of movement through a range of little less than half a circle, as shown in Fig. 14, but the one I show you with curved spine and inclined sternum is all but rigid.

What is the nature then, we ask, of the mechanical difficulty introduced into the arrangement by curving the spine and placing the sternum in an inclined position towards it? To understand this, let the two lower levers, G F and K H, in Fig. 13 be detached from the sternum L, then it will be found that the sternum may, still having the two upper levers connected with it, be moved through a very considerable range either upwards or downwards—a range not so great as in Hamberger's machine, but not very much short of it. If, having elevated the sternum L until E D attains to the position E D' perpendicular to A N, we seek to reapply G F and K H to it at their former points of attachment to A F' and H', we shall find they are too short to reach to these points, as is shown in the diagram; and the degree of incompetency of the fourth lever, K H, is still greater than that of the third lever, G F; and if there were a fifth lever, the deficiency there would be still greater,—and so on increasing for every additional lever downwards. If the sternum be gradually depressed again, a point of depression will be reached where G F and K H may once more be attached to the sternal bar. If from the position L it be now attempted to carry the sternum in a downward direction, it will soon come to a standstill; and if now all the levers but the upper two be detached, and depression, which thus becomes possible, be made, it will be found on endeavouring to reapply the

upper levers that they are now too long, their extremities project beyond the proper points of attachment. In this arrangement, then, in Fig. 13 with the inclined sternum the range of movement upwards is limited, because the lower levers will not lengthen, and downwards because they will not shorten. And the range is made enormously more limited when the spinal column has the natural curvature given to it. For an explanation of this in more precise terms let us look at this parallelogrammic model, Fig. 4; the articulations of the four levers with the sternal piece are all in a perpendicular line, they are in the same vertical plane. If I elevate to the position L' in Fig. 14, they still all lie in one plane; so also if depressed to L. In whatever phase of elevation or depression, having got the plane in which two of these anterior articulations lie, in that same plane all the others will be found. In the apparatus having the inclined sternum and curved spine, in the first original position L, Fig. 13, the anterior ends of the four levers lie also in one vertical plane. Detaching the lower levers and raising the sternum with its two upper levers to the position in which the second lever becomes perpendicular to the spine, B' and D' are in the same plane; but if now the third lever be moved upwards through such an angular distance as will bring its anterior extremity opposite to its proper point of attachment to the sternal line, it will not be in the same plane as are B' and D'; and if I elevate the fourth lever through such an angular distance as will bring its anterior end opposite to its proper point of attachment, it will be found in a plane different from that in which B' and D' together lie, or that in which D' and F' together would lie. One plane joins the first and second, another the second and third, and still another the third and fourth anterior ends of the levers in

their elevated positions. The straight line that joined all these anterior extremities of the ribs in their first position (L) would, to permit of elevation, need to be broken into as many pieces as there are interspaces, and each piece would be part of a plane different from the plane of any of the others. The curvature of the spine, and the inclined position of the sternum to the spine, thus unite to introduce a mechanical hindrance that would render impossible the necessary movements of the thoracic walls in respiration, were it not that an expedient is resorted to by which the difficulty is overcome. On looking at Fig. 13 the idea suggests itself that the mechanical difficulty might be obviated if the sternum were made sufficiently flexible to allow of its being curved backwards during inspiration, and so make up for the shortcoming of the lower ribs. And experiment shows that to a minute fractional extent the sternum in inspiration does yield in the way I have indicated. But this is extremely small even in the sternum of a child, and is infinitesimal in the case of the ossified sternum of the adult in normal respiration. Indeed, if the sternum were to any large extent so to adapt itself to this mechanical exigence by its lower portion becoming curved to the necessary extent, the antero-posterior increase of thoracic area, which is a principal end sought in the elevation of the sternum, would be very materially interfered with, as full antero-posterior enlargement would then take place only at the upper and shallower part of the thorax. But another expedient suggests itself. The rib levers proceed from the spine to the sternum by a long curved course round one-half of the body. Obviously if these lower levers would but consent to straighten themselves somewhat in inspiration, the mechanical shortening might be met. And again, as in the case of the sternum, there is a slight yielding in the required direction, but it is again only to a minute fractional extent of what would be required were the difficulty to be met by this means alone. For were there any great yielding here it would be at the expense of increase in the transverse diameter of the chest, and to that extent the inspiratory enlargement would be interfered with. But a method is called in aid that in no way compromises the inspiratory enlargement of the thorax, but, on the contrary, of itself very greatly adds thereto. The rib is not directly connected with the sternum, there being between the sternum and every rib a shorter or longer costal cartilage. In the case of the first rib this cartilage is very short, and its direction is just the continuation of the direction of the rib itself. The second cartilage is longer than the first; in many cases it pursues the same course towards the sternum as the rib itself, but in others, instead of continuing the downward direction of the rib, it curves upwards somewhat in its way to the sternum, and forms with the rib an obtuse angle. In the case of the third rib, the cartilage is considerably longer than that of the second, and in every instance it departs from the course pursued by the rib, always curving up to join the sternum, and always making an angle with the rib, an angle less obtuse than the angle formed by the second rib and cartilage. The fourth cartilage, again, is longer than the third, and the angle it makes with its rib more acute than the third angle; and, descending, we find that every succeeding cartilage is longer than the one above, and all the angles are more acute than the upper four. In this cast from a frozen subject, the cartilages increase in length from the first, which is  $1\frac{1}{2}$  in., to the seventh, which is  $2\frac{1}{2}$  in. The influence of the eighth rib on the sternum is exerted through means of a length of cartilage of  $3\frac{1}{2}$  in., the ninth by a cartilage of five inches, the tenth by a cartilage of  $6\frac{1}{2}$  in. By this structural arrangement thoracic movement is made possible, for, in inspiration, by the opening of the costo-cartilagic angle each combined rib and cartilage becomes longer. Our trapezoidal machine (Fig. 13) showed us that in the case of the two upper rib levers, no mechanical difficulty exists, and nature accordingly does not provide any mechanical expedient for lengthening them. But, from this downwards, help is required, and that in a greater and greater degree as we descend, and to a greater and greater degree it is given, just in proportion to the need of it, for the fourth combined rib and cartilage permits of greater lengthening than the third, the fifth than the fourth, and so on until in the lower ribs that have sternal connexions it becomes enormous. In this model (Fig. 15) is shown the effect of introducing parts corresponding to the costal cartilages and free movement is allowed, while in this arrangement (Fig. 13) without them almost complete rigidity would prevail. The opening of these costo-cartilagic angles occurs to a less or

greater extent in every inspiration. Taking, for example, the seventh costo-cartilagial angle on the left side, I found that an inch and a half above the apex of the angle with a deep

FIG 15.

inspiration the transverse distance between rib and cartilage was increased as follows:—

Male, aged 39	...	Normal chest,	$\frac{5}{16}$ inch.
" " 40	...	" "	$\frac{3}{8}$ "
" " 47	...	Slight Bronchitis,	$\frac{3}{8}$ "
" " 18	...	" "	$\frac{1}{8}$ "
" " 47	...	Mitral disease,	$\frac{1}{8}$ "
" " 32	...	" "	$\frac{1}{8}$ "

The mechanical difficulty introduced by the curved form of the spine and the inclined position of the sternum is thus obviated in a most effective and beautiful manner by a means that in no way militates against the great object that is in view in the elevation of the costal parietes—the increase of the thoracic capacity. On the contrary, this very expedient in itself increases the internal area—the cartilages being, in fact, the representatives in man of the sternal ribs of birds, in virtue of which they are enabled to meet their enormous respiratory wants. And this is another instance showing the conservative principles on which nature proceeds in all relating to mechanics, that here, instead of introducing some new and special mechanical expedient to convert an otherwise rigid framework into a freely movable machine, she merely retains so much of the sternal rib as will suffice; and as if further to show her economical tendency, the cartilages of the upper two ribs, where adaptive assistance is scarcely required, are in most instances quite rudimentary.

## A SIMPLE OPERATION FOR VARICOCELE.

By ARTHUR E. BARKER, F.R.C.S.ENG.,

ASSISTANT PROFESSOR OF CLINICAL SURGERY, AND ASSISTANT SURGEON AT UNIVERSITY COLLEGE HOSPITAL.

In the last three cases of varicocele upon which I have been called to operate, the method adopted has been very simple, and has been followed by such good results that it appears worth brief notice. It seems, too, very unlikely to be followed by any of those ill results and dangers of which most surgeons have seen something who have practised the older procedures. I may say that the three operations now

recorded were done by way of experiment. Some time previously I had removed the enlarged right half of the thyroid gland with strict Listerian antiseptics, using seventeen silk and six catgut ligatures for vessels, &c. The wound healed rapidly (almost by first intention), although after the first day I used a dressing of salicylic wool without the spray, the wound having become fully exposed during the first night. Here not one of either the catgut or silk ligatures came away or gave any evidence of their presence under the skin; nor have they done so yet, nearly a year after operation. In thinking over this case, it occurred to me that the scrotum, from its position and structure, would be a good field in which to study (as far as this is possible in the living body) the behaviour of such ligatures embedded in healthy tissues. If no suppuration took place around them, we might be able by manipulation to ascertain how long they remained unabsorbed, and how much plastic change they provoked, with some other interesting points. If, on the other hand, they should suppurate and come away sooner or later, the patient would be in no worse condition than if operated on by one of the ordinary methods where suppuration is necessary. I also thought that it would be interesting to try whether it was not possible in this ligation to attain to and maintain perfect asepticity without the usual elaborate dressings of the Listerian method. The operation of tying the veins of the testicle, in short, appeared to offer a simple but fairly good means of testing practically whether it was possible, without the spray, to introduce a perfectly pure ligature into the tissues of the body, and to maintain such conditions of purity around it as might enable the silk to remain there without provoking any excessive reaction; also of observing what became of the knotted ligature eventually in the soft textures of the scrotum.

Having these three cases to operate on last autumn, I dealt with them as follows: two on one day, the other five days later. The skin of the scrotum was thoroughly cleansed with a 5 per cent. carbolic lotion, as also all instruments and the surgeon's hands, no spray being used. The scrotum was then pinched up between finger and thumb in the usual way, so as to include the veins and exclude the vas deferens; it was then notched with a scalpel, and through the opening thus made a needle bearing a medium-sized twisted silk ligature (previously soaked for about an hour in the same carbolic solution) was passed. The veins were then allowed to slip backwards, and the needle was made to carry the silk forwards again through the same puncture, but this time in front of the veins. The latter were thus, of course, included in the two loops of silk leaving the scrotum by the same aperture. The ends of these were now tied tightly over the veins about one-eighth of an inch apart. They were then cut short and allowed to slip into the scrotal tissues. Everything was in the meantime protected from any contamination by frequent wiping with a carbolic sponge. A little padding of salicylated wool was the only dressing.

The results need only be briefly alluded to. There was a very trifling swelling around the seat of ligature for a few days, together with slight tenderness on pressure, otherwise nothing was complained of in the first two cases. In the third, considerable pain was felt for a day or two, and there was a little more swelling and tenderness. But in none of the three cases was there the slightest threatening of suppuration. The first left the house in ten days, the second within a fortnight, the last on the fourteenth day. They were then walking about without any discomfort, except the third, who, having had a very large varicocele, still felt a good deal of dragging in the loin on returning to his work, which was very hard, and some neuralgic pain. These, however, passed off later, under the use of laxatives for obstinate constipation from which he suffered, though he continued to work for long hours as a grocer's assistant. I watched all these three cases for several months, the last until quite recently, about a year after operation, and now regard all danger of the ligatures coming away as quite over. The latter could be felt under the finger as small knots deep in the scrotal tissues, which appeared quite normal. Whether they will ever come away remains to be seen, but this is immaterial, as far as the patient is concerned, for they give no trouble now.

Comparing these operations, as far as they go, with the older methods, their extreme simplicity is worth noting, as well as the small amount of trouble or inconvenience to the patient. It is also of some interest to note that, in these

three cases at all events, it was possible to manipulate freely with silk ligatures, and yet introduce them in a sufficiently pure state to produce no suppuration of any kind; and all this with only the simplest precautions as to absolute cleanliness, and without the carbolic spray. There is also a satisfaction in knowing that the veins are thoroughly occluded, and that there is no possibility of the ligatures slipping or being too soon absorbed, as might be the case with catgut. If nothing else, the operation appears an interesting experiment, and worthy of further trial.

Harley-street, W.

### CASE OF STRUMOUS ULCERATION OF THE INTESTINES, PRESENTING THE CLINICAL FEATURES OF ACUTE GENERAL TUBERCULOSIS.

By SAMUEL WEST, M.B., &c.,

SENIOR ASSISTANT PHYSICIAN TO THE CHEST HOSPITAL VICTORIA-PARK, ETC.

DR. STURGES remarks in his article on Acute Tuberculosis in THE LANCET of September 16th, that "tubercular individuals, children at all events, will present the clinical symptoms of tubercular meningitis, and die in the usual way, but post mortem neither tubercle nor inflammatory exudation will be discovered." The following case is an illustration of this.

On August 17th a child, nine years of age, was brought to the Chest Hospital, Victoria-park, by its mother, who stated that though never strong, the child had been in its usual health until the last six weeks, when it became weak and languid; that for the last fourteen days it had been feverish, and had suffered from pain and sickness chiefly after food, and a little diarrhoea. There was no history of any previous illness. The child was thin and feverish, looked dull, and had an aspect which suggested typhoid fever. The pulse was rapid, 100-120; the temperature was high, with marked evening rise, 101.5° to 102.5°, the morning temperature being nearly normal. The child was listless, heavy, and slept much. The condition remained the same for some days. Diarrhoea, spots, and abdominal pain were absent, and the abdomen retracted. At the right apex the percussion was slightly impaired. The respiratory sounds were increased, especially the expiration sound, which was remarkably long and harsh, accompanied by occasional fine crepitation. The absence of abdominal symptoms and the presence of pulmonary signs led to the probable diagnosis of acute general tuberculosis, which was confirmed, it was thought, by the further course of the case. For the apex dullness increased slightly, some general bronchitis set in, and the patient rapidly lost flesh and strength; on the 6th of September—i.e., at the end of the fifth week of severe illness, and nine weeks from the commencement of failing health, the child, having for some days previously grown more and more drowsy, became suddenly unconscious, the eyes remaining wide open, the pupils equally dilated and not responding to light. There were continual slight twitchings of the feet and hands with irregular movement of the eyeballs; the respiration was noisy and harsh; the urine and faeces were passed unconsciously. For the next two days the temperature rose higher than usual, above 103°, the general condition remaining the same. On September 9th the temperature began gradually to fall, the twitching ceased, the pupils were observed to dilate and contract spontaneously, as in many cases of meningitis, and several loose motions were passed in bed unconsciously. On the 10th there was a slight return of twitching in the eyelids and arms, the respiration became embarrassed, and in the evening the patient died.

The history of the case, the retraction of the abdomen, the absence of diarrhoea, the presence of lung symptoms, and their gradual increase, and, lastly, the occurrence of unconsciousness, with slight convulsions, were all thought to point conclusively to the diagnosis of acute general tuberculosis. This diagnosis, however, the post-mortem examination did not establish. In no organ was there the slightest trace of grey tubercle. The apex of the right lung was indurated by some old pigmented fibrous tissue, but there was no recent mischief. The brain was absolutely

healthy, except for the presence of a small cyst (a quarter of an inch in diameter) in the middle of the nucleus. This cyst had a firm fibrous capsule, with smooth lining, and round it the nerve substance was perfectly healthy; so that there was no sufficient explanation in the presence of the cyst for the sudden occurrence of unconsciousness. All the other organs were sound, except the intestines, which were in a most extreme condition of "tubercular" ulceration. In the whole caecum round the valve, and for the lower six inches of the ileum, the mucous membrane was completely ulcerated away, and at frequent intervals in the small intestines large tubercular ulcers were found, many completely encircling the gut. The last ulcer, and that too of considerable size, was at a distance of only two feet from the duodenum; the character of the ulceration was typical of the so-called tubercular or strumous ulcers of the intestine, and the glands of the mesentery were also in the condition usual in this affection.

The uncertainty of diagnosis between many cases of acute general tuberculosis and typhoid fever is generally recognised, but this case is an instance of an intestinal lesion, not typhoid, which presented the same difficulties.

Wimpole street, W.

### PURULENT DISEASE OF THE EAR;

PRODUCING CEREBRAL ABSCESS, PURULENT MENINGITIS, AND OBLITERATION OF THE RIGHT LATERAL SINUS, WITH STRIKING CHANGES IN THE INTERIOR OF THE TEMPORAL BONE.<sup>1</sup>

By THOS. BARR, M.D., F.F.P.S. GLAS.,

LECTURER ON AURAL SURGERY, ANDERSON'S COLLEGE, AND DISPENSARY SURGEON FOR DISEASES OF THE EAR, WESTERN INFIRMARY, GLASGOW.

W. C—, a boilermaker, aged thirty-seven years, was a remarkably strong man, of great muscular development and of medium height, weighing in ordinary health between fourteen and fifteen stones. He suffered from purulent disease of the right ear from the age of twelve till his death—that is, for twenty-five years. There was almost total deafness on the affected side. The disease was supposed to have originated in the blow of a cane received on the right side of the head, and inflicted by a schoolmaster by way of chastisement. This injury was followed by great pain, continuing for several weeks and culminating in the formation of an abscess which was opened behind the auricle. About the same time a discharge of matter appeared from the external auditory canal. The purulent discharge from the opening behind the ear continued, with variations in quantity, till six years ago, when the opening closed, leaving behind a depressed cicatrix. The discharge from the canal of the ear, which had usually an offensive odour, continued, with slight intermissions, till the patient's death. It was slighter, however, during the nine months before his fatal illness. He was liable during cold weather to attacks of hoarseness with sore-throat. At the age of seventeen he suffered from acute inflammatory attacks in the right ear, when it was supposed that his life was in danger. He noticed that when the discharge ceased for a short time he suffered from severe headache, and became very dull and fretful. Indulgence in alcoholic stimulants produced the same effects, and he was therefore very temperate in their use. In the middle of November last there began a series of morbid processes—first in the left ear, then in the right,—which in the course of three months terminated fatally by extension of the purulent inflammatory process to the interior of the cranium. The left ear, which previously had been always healthy, and in which he enjoyed good hearing, became at that time dull and discharged slightly without any distinct pain. This was associated at the beginning with sore-throat and hoarseness. The dullness and slight discharge in the left ear continued for two months, at the end of which an acute inflammatory process began in the ear. While at work on Monday, Jan. 23rd of this year, and particularly on his way home at the end of the day, he experienced great giddiness, so that at times he staggered in walking. On the following morning at four o'clock he awoke with severe pain in the head, with great giddiness, and he looked

<sup>1</sup> I am indebted to my friend Dr. McConville, the medical attendant of this patient, for the chief facts given in the clinical history.

deadly pale. Dr. McConville was sent for in the forenoon, when he found the patient "suffering from great pain on both sides of the head, but chiefly on the left side. The left auricle projected abnormally from the side of the head, and the meatus was almost closed by swelling of its walls. There was a general feeling of uneasiness and tenderness in the temporal and mastoid regions. The cervical glands immediately behind the lobule were much swollen and painful." The deafness on the left side was now almost as complete as on the right, and only the shrill voice of a female friend exerted at its highest pitch close to the left ear could be heard by the patient. Dr. McConville then, for the first time, examined the right ear. He found over the upper part of the mastoid region, a little distance behind and above the auricle, a depressed cicatrix adhering to the subjacent bone. The canal of the ear was filled with pus, and on its removal by syringing with warm water a few granulations were seen at the inner end of the canal. There was some bronchitis and pharyngeal catarrh, along with febrile disturbance and thickly coated tongue.

The treatment carried out by Dr. McConville consisted in the local abstraction of blood by leeches applied in front of and below the left auricle, in the use of poppyhead fomentations and hot linseed-meal poultices to both sides of the head, and in the use of a gargle of chlorate of potash. The general treatment included catharsis by jalap and calomel, followed by the use of a mixture containing iodide of potassium, chloride of ammonia, and an anodyne for the cough. After a few days a large cantharides plaster was applied to the back of the head, from ear to ear, with apparently considerable relief to the pain and the giddiness. The man's condition seemed to improve. After a few days the painful symptoms passed off, and the hearing was partially regained in the left ear. This improvement continued, exciting lively hopes of recovery, which were, however, changed to bitter disappointment, for in the course of another week grave and ominous symptoms appeared.

On Saturday evening, twelve days after the first attack of giddiness, the patient experienced a sense of chilliness; pain was complained of, not on the left, but on the right side, the seat of the old purulent disease. Dr. McConville then ordered forty grains of Bromide of potassium and ten grains of chloral to be taken night and morning. The next morning the man felt so well that he proposed to take a walk in the West-end park; but to this the doctor distinctly objected as a possibly dangerous exposure to cold. That evening he had another chill. From this day the symptoms became most grave, and indicated serious mischief in the interior of the cranium. The pain in the head—chiefly in the front—became daily more intense. Nights were passed in agony, which anodynes, externally and internally applied, only partially mitigated. The patient was seized with repeated rigors. In these rigors the arms and legs shook violently. These rigors or shakings soon took the character of epileptiform convulsions.

I was asked by Dr. McConville to see the patient on Wednesday, Feb. 15th, seven days before his death. The man then lay in a stupor, but was capable of being roused; there was extreme deafness, loud shouting into the left ear being necessary before he heard and understood. I asked him about the pain in the head. He answered, slowly prolonging the word, "excruciating." I found no tenderness in the right ear, or in its neighbourhood. The orifice behind the ear was now open, and fluid injected into the opening passed quickly and freely through the canal of the ear. The current could also be forced as easily in the opposite direction. Disinfecting fluids were afterwards regularly and frequently forced through the ear by this means. It was apparent, however, that the mischief was in the interior of the cranium, and a cerebral abscess was diagnosed. Up till four days of his death he was able at times to get out of bed, and even to walk from the room to the kitchen. Four days before death he was seized with paralysis of the left arm and leg and right side of the face. For two days before death he was quite comatose. He died on the evening of Wednesday, February the 22nd, about a month after he left his work and sixteen days after the more definite brain symptoms set in.

The autopsy was made by Dr. James Alexander Adams, twenty-four hours after death. Under the calvaria the veins of the dura mater were seen to be torpid. On clipping away the exposed dura mater the middle part of the upper surface of the right cerebral hemisphere presented a slightly bulging appearance, but the surfaces of the hemi-

spheres appeared to be otherwise normal. At this stage of the examination no unusual odour was apparent from the intra-cranial contents, but while removing the brain from the base of the skull, when the right temporal lobe was raised from the middle fossa of the skull an extremely disagreeable fetid odour was suddenly experienced. A small quantity of purulent matter was at the same time seen on the floor of the middle fossa of the right side. The brain being placed with its base upwards, the lower surface of the right temporal lobe corresponding with the upper surface of the petrous part of the temporal bone was seen to be dark in colour and very soft to the touch, but having no apertures in its substance. On cutting into the temporal lobe at this part, however, a thin brownish fluid, emitting a most offensive smell, poured out in considerable quantity; and on making further sections, the lateral ventricle and a great part of the interior of the right cerebral hemisphere seemed to be occupied by this fluid. There was no distinct boundary wall or membrane enclosing this collection of fluid, but the substance of the brain around seemed in a softened, at some parts even gangrenous, condition. The temporal bones were removed for careful examination. Right temporal bone: The dura mater covering the upper surface of the petrous part of the bone was swollen, soft, and pulpy, and was perforated by two small apertures. The portion of dura mater covering the roof of the antrum mastoideum was more thickened than elsewhere. The bone beneath was dark coloured and eroded; at one part it was perforated by a considerable carious opening communicat-

FIG. 1.

The outer part of the section of the right temporal bone. *a*, Outer part of the dilated antrum mastoideum, showing the three openings communicating with the external auditory canal, and one communicating with the interior of the cranium. *b*, The dense compact tissue into which the mastoid cells are converted. *c*, Section of inner end of external auditory canal. *d*, Inner end of canal passing to the outer surface of the mastoid process. *e*, Dura mater.

ing with the antrum mastoideum. After a time the colour of the bone changed, and instead of being dark, it assumed a bleached and white appearance. Behind, the dura mater covering the concavity for the lateral sinus, and forming the walls of that sinus, was extremely thickened and converted into a fleshy mass. The lumen of the lateral sinus was completely obliterated by thickening of its walls and by fibrous adhesions of its inner coats. Some purulent matter was found infiltrated between this thickened mass and the bone forming the inner wall of the antrum mastoideum. This osseous wall was found to be very thin, very much eroded on its inner surface, and perforated at one part by an opening leading to the antrum mastoideum. On the outer surface of the mastoid process just behind the root of the zygoma, and about ten millimetres above and behind the external orifice of the osseous part of the canal of the ear, there was an opening in the bone four millimetres in diameter, which communicated at a distance of five millimetres with the antrum mastoideum. The bone, perforated by this channel, was dense and hard as ivory. On examining the osseous part of the external auditory canal, the posterior wall was found extremely thinned and perforated by three small apertures. This extremely thin perforated plate of bone formed a partition between the external auditory canal and the dilated antrum mastoideum. At the inner end of this posterior wall there was a large semilunar gap, with

the convexity outwards, which passed into the antrum mastoideum. A vertical antero-posterior section through the middle ear exposed a very unusual condition of the tympanum and mastoid cells. The whole of the normal contents of the tympanum were gone; there was not a vestige of the tympanic membrane or ossicular chain remaining. There was complete osseous closure of the fenestra ovalis. The fenestra rotunda, however, still remained. The promontory and floor of the tympanum were covered with soft granulation tissue. A white nipple-shaped hyperostotic growth, with two or three vertical grooves, occupied the position of the outer and inferior semicircular canals. Above that an excavation extended inwards nearly as far as the posterior surface of the petrous bone. The bone forming the floor of the tympanum was enormously thickened (twelve millimetres in thickness), and very dense. The mastoid cells had undergone a remarkable change. The antrum mastoideum was immensely dilated, forming a cavity two and a half centimetres long from within outwards, and nearly two centimetres from the back wall of the external auditory canal to the thin cortical layer separating the antrum from the groove for the lateral sinus, while it measured in height more than one centimetre and a half. The outer wall of this cavity was smooth and white, while the inner one was lined with granulation tissue. The mastoid cells proper were sclerosed and completely obliterated and, instead of large numbers of air-filled spaces, as in the normal condition, I found extremely hard, dense,

FIG. 2.

The inner half of the section of the right temporal bone. *a*, Inner part of the dilated antrum mastoideum. *b*, The dense compact tissue into which the mastoid cells are converted. *c*, Cavity of the tympanum. *d*, Dura mater. *e*, Inner wall of osseous part of Eustachian tube.

ivory-looking bone, through which I had great difficulty in working the saw. The two cavities, the tympanum and the greatly dilated antrum mastoideum, were filled with thick curdy matter, having a most fetid odour. Left temporal bone: The dura mater over the petrous part was normal. The osseous roof of the middle ear was also apparently free from pathological change. On examining the tympanic membrane I found a small round perforation, about two millimetres in diameter, in the posterior part of the membrane flaccida. This opening was partially closed by granulation tissue. On removing the roof of the middle ear I saw that the head of the malleus and the body of the incus were gone, and that the opening in the membrane communicated with the antrum mastoideum. The latter cavity was filled with muco-purulent fluid. The osseous layer forming the floor of the tympanic cavity was only about two millimetres in thickness, markedly contrasting with the right side, where the floor of the tympanum measured twelve millimetres in depth.

*Remarks*—In this single case we have an illustration in the right side of almost all the various consequences, both to the ear itself and to the interior of the cranium, following upon chronic purulent disease of the middle ear. The changes produced in the ear itself were: (1) Total loss of the tympanic membrane and ossicular chain; (2) osseous closure of the fenestra ovalis; (3) great dilatation of the cavities of the tympanum and antrum mastoideum; (4) conversion of the cellular structure of the mastoid cells into dense tissue of almost ivory consistence; (5) the formation of six carious

apertures opening into the dilated antrum mastoideum—namely, two communicating with the interior of the cranium, one perforating the outer wall of the mastoid process, and three passing into the external auditory canal. The changes produced by extension of the disease to the interior of the cranium were also very remarkable. The brain, the dura mater, and the lateral sinus were all three involved in serious morbid changes, including cerebral abscess, purulent meningitis, and changes in the lateral sinus producing closure of that channel. We have thus represented in this case all the morbid processes known to be the chief modes in which disease of the ear leads to a fatal issue. It is undoubtedly very rare to find the whole three present in the case of one patient. The condition of the lateral sinus is probably the most striking and interesting feature in this case. No doubt some degree of phlebitis of the lateral sinus is a not unfrequent complication of purulent disease of the middle ear. The mischief is, however, probably in most cases limited to some thickening of the walls of the sinus, and to a consequent diminution of its lumen. In regard to the frequency of the implication of the sinuses of the brain, Wreden gives as his experience that 14 per cent. of purulent ear disease are complicated by thrombosis of the sinuses of the interior of the cranium, while Dusch found that out of thirty-two cases of thrombosis of these sinuses twenty originated in purulent disease of the ear. Of the venous sinuses of the brain the lateral is much the most exposed to injurious influences from the ear. This is due to its anatomical connexion with the mastoid cells. In the deep concavity of the groove for the lateral sinus only a thin osseous partition separates the mastoid cells from the walls of the sinus. This partition is always perforated by openings for the passage of connective tissue, vessels, and nerves. Besides, it is not only frequently so thin as to be transparent, but it is no very uncommon thing to find it containing small gaps, in which case the mucous lining of the middle ear and the wall of the sinus are in direct contact. In the case before us the state of this osseous partition, eroded and perforated by carious disease, affords a ready explanation of the mode of extension of the disease in the ear to the walls of the lateral sinus. But without such disease of the bone the simple juxtaposition of the lateral sinus with the ear is in suppurative disease a source of great danger. All surgeons know that phlebitis and thrombosis are very apt to form in the vessels of a tissue which is the seat of purulent inflammation. When therefore, as is frequently the case, the lining of the mastoid cells is chronically inflamed, softened, or eroded, and when these cells are filled with decomposing purulent matter, emanating gases of putrefaction, is it surprising that phlebitis and thrombosis with their effects should be set up in this large venous trunk, so closely contiguous to and so connected by bloodvessels with the diseased part? More frequent extension of disease in the middle ear to the lateral sinus would take place but for two obstacles opposed by nature to such extension. First, the natural power of resistance presented by the strong tissue of the dura mater, which forms the walls of the sinus, even when this dura mater is in actual contact with a diseased part. In such circumstances the walls of the sinus may become merely thickened without further mischief. For example, necrosed and carious bone has been found in contact with the walls of the lateral sinus, without more mischief than some thickening of the walls of the latter. Secondly, the thickened lining membrane of the middle ear, together with the thickened osseous walls of the latter, circumscribes the morbid process in the ear and frequently forms an important barrier erected by nature against the invasion of this great venous channel of the brain by the disease in the ear. This case is one more added to the large record, which the literature of this subject presents, of fatal results arising out of old and neglected purulent disease of the ear. It is to be feared that, in spite of this dismal record, chronic purulent disease of the middle ear, frequently manifesting itself by the single symptom of a discharge from the ear, is still viewed in too many cases with indifference by the profession as well as by the public.

Albany-place, Glasgow.

At the Worship-street Police Court last week a manufacturer of German sausages in the East-end of London was fined £20, with costs, for using horseflesh, some of it in a state of decomposition, in the composition of the articles of food vended by him.

FATAL CASE OF ACUTE LOCAL ENTERITIS  
OF UNDETERMINED CAUSE.

By HENRY S. GABBETT, M.D., M.R.C.P.,

MEDICAL REGISTRAR TO THE LONDON HOSPITAL, ASSISTANT-PHYSICIAN  
TO THE ROYAL CHEST HOSPITAL.

L. B—, a porter at the Royal Chest Hospital, aged forty-three, was suddenly seized with violent abdominal pain on the morning of April 21st. He was a married man with several children. He had always enjoyed robust health, but there was reason to believe that he was intemperate in the use of alcohol. On the morning above mentioned he was called for early at his own house, got up, opened the street door, and on returning to his room was attacked with colicky pains, soon succeeded by vomiting. Dr. Burgess, the resident medical officer of the hospital, was called to see him, and found him suffering from paroxysmal pain referred to a spot midway between the umbilicus and the pubes. I am indebted to Dr. Burgess for notes of the patient's condition at this time. From them I learn that the man complained of constant distress in the region described, aggravated every two or three minutes until it became so severe as to cause him to cry out and to double himself up with pain. The bladder was not distended; there had been no motion from the bowel on that day. He vomited whenever he took food. There was no history of previous constipation, and his last meal had been a simple one of meat for supper on the evening preceding his illness. He was given a draught containing castor oil and laudanum, which (according to his wife's statement) moved his bowels very slightly a short time after its administration. The symptoms continued unchanged during the day. He frequently vomited, and suffered from tenesmus. He passed a very restless night. On the following morning, April 22nd, I was asked by Dr. Burgess to see the patient. I found him lying on his back in bed, his knees not drawn up; his face rather pinched, and wearing an expression of anxiety; his pulse small and fast, about 110; his temperature 99.5°. His tongue was slightly dry, but not furred; he complained of thirst; and during my visit he retched ineffectually two or three times. The abdomen was moderately distended; there was no general tenderness, but pressure in the hypogastric region, a little to the right of the median line, caused pain. There had been no motion from the bowels since that mentioned above; the secretion of urine was very scanty. Two attacks of colicky pain occurred in my presence; they came on rather rapidly, the recti muscles contracted strongly, and the patient tried to bend himself forward, making exclamations indicative of distress. For many reasons it was considered advisable to remove him to the hospital; he did not seem to suffer from the journey, which was a short one. After his admission, the application of hot fomentations with laudanum seemed to give relief to the abdominal pain; the vomiting became less frequent, the vomit consisting of small quantities of green, bilious fluid. The urine was examined, and found to be highly concentrated and to contain a trace of albumen. It was considered probable that the case was one of acute intestinal obstruction. The seat of obstruction could not be ascertained; there was certainly no external hernia; there was no passage of blood from the bowel; digital examination of the rectum gave negative results. Enemas were given without any effect, but the patient asserted that he passed flatus after them and obtained some relief thereby. He was now ordered frequent doses of belladonna. I saw him again at 2 P.M., and found him certainly more comfortable, complaining but little of any pain, and vomiting very seldom; but he hiccupped occasionally, was thirsty, and his pulse was, if anything, worse than in the morning. He was able to swallow and retain concentrated nourishment. There had been no motion of the bowels, and no desire to evacuate on the part of the patient. Dr. Gilbert Smith was kind enough to see him with me at 5 P.M., and gave a very gloomy prognosis. At this time, although the man considered himself better, his pulse was exceedingly rapid and shaky, his breathing thoracic, and his abdomen more tumid than before. The previous treatment was continued by Dr. Gilbert Smith's advice—that is, nourishment and stimulants in small repeated doses, belladonna,

and opium if necessary, to relieve pain. I visited the patient for the last time that evening at 10. There was then no obvious change in his condition; he was perspiring freely, the temperature had never reached 100°; his mind was clear; he vomited a little bilious fluid at long intervals, and complained of some general abdominal pain, which was not at all severe. It was noted, however, as an unfavourable prognostic, that there was a tendency to jactitation, and that the pulse had by no means improved. I am informed by the resident medical officer that the patient was very restless during the night, that during the early hours of the morning he showed some signs of incipient delirium, and that at 7 A.M. he suddenly sat up, tried to get out of bed, and almost immediately fell back and died, brownish-yellow fluid pouring in large quantities from his mouth. Up to this the vomit had been throughout merely bilious. Death occurred forty-eight hours after the commencement of the illness.

The post-mortem examination was made by Dr. Burgess, assisted by Dr. Gilbert Smith and myself, twenty-six hours after death. On opening the abdomen we found evidences of general peritonitis; flakes of lymph covered the intestines, the coils of which were reddened, especially at their points of contact; and the abdominal cavity contained several ounces of turbid yellow fluid. Great care was taken to avoid disturbing the position of the viscera whilst a general inspection was being made. There was no band, twist, intussusception, or internal hernia. Attention was immediately attracted by the appearance of a piece of intestine, about three inches long, lying in the middle line of the hypogastric region; it was intensely congested, of a uniform deep-red colour, and contrasted strongly with the neighbouring coils. It was found to be a portion of the ileum, nearly two feet distant from the ileo-cæcal valve. There was no such sharply defined line of demarcation either above or below the coil as is observed in cases of strangulation, but the deep-red colour shaded off very rapidly on both sides. The portion of mesentery belonging to the coil contained between its layers an oblong dark-purple mass. The ileum above this congested piece, the jejunum, duodenum, and stomach were all greatly distended, and filled with brownish-yellow liquid without faecal odour. No perforation was discovered. The last two feet of the ileum contained a thick pasty material; this part was neither much dilated nor contracted. The cæcum and first part of the colon contained yellow faeces in considerable quantity; the sigmoid flexure and rectum were empty. Examination of the intestinal mucous membrane showed no evidence of diffuse enteritis; but in the intensely inflamed coil of ileum the mucous membrane was swollen and covered with sticky mucus. No part of the canal contained blood. The purple mass in the mesentery proved to consist of lymphatic glands with hæmorrhage in their substance and around them; other glands in the immediate neighbourhood were enlarged and so soft as to be absolutely diffident. The mass in the mesentery was about an inch and a half long, and communicated by means of a thin line of effused blood with a very small extravasation beneath the mucous membrane. A microscopic examination of parts of the glands and of the inflamed bowel revealed nothing further than had been ascertained by the naked eye. The mesenteric vessels appeared healthy, and there was no sign of embolism. The liver was soft and fatty. There was a small cyst in the left kidney. The heart was healthy; the left ventricle firmly contracted. There was acute diaphragmatic pleurisy on the right side. No other morbid appearances were observed.

*Remarks.*—It appears almost certain from a review of the clinical history and the post-mortem appearances that this was a case of local damage to the intestine, giving rise to local enteritis at first, then to obstruction from paralysis of the muscular coat, and finally to general peritonitis. It is difficult, if not impossible, to ascertain the nature of the original lesion. During life it was considered possible that there had been some accidental twist of the bowel, or that a knuckle had been suddenly constricted by a band or otherwise, or that an intussusception had occurred. Some such injury was supposed to have happened, because of the nature of the symptoms and their mode of onset after the patient had suddenly risen from bed. The theory of an intussusception was rendered to some extent improbable by the absence of physical signs and by the fact that no blood was passed per rectum; but that something of the nature of an accident did occur appeared, and still appears,

in the highest degree probable. What could this accident have been, regarding the matter in the light of the post-mortem appearances? If it was a twist or an intussusception, then the bowel must have recovered its original shape after the lesion had set up the inflammation which terminated in death. But even supposing the possibility of such recovery, would there not have been more definite appearances in the mucous and serous membranes to indicate the accident? On the whole, I feel unable to suggest any explanation of the phenomena; the only thing which at the time seemed to give a clue (and that by no means a satisfactory one) was the discovery of a hæmorrhage between the layers of the mesentery adjoining the inflamed piece of bowel. Whether this can have been the primary accident is a question which I cannot attempt to determine; but it is interesting to note that there have been recorded cases of mesenteric hæmorrhage discovered post mortem, in which no other cause was found for the fatal event. (See report of meeting of the Medical Society, December 5th, 1881, THE LANCET, December 31st.) The immediate cause for the somewhat remarkably sudden death in the present case was in all probability acute distension of the stomach by upward overflow of the contents of the small intestine. Up to the moment before death the vomit was simply bilious; at the moment of death, yellow fluid poured in quantities from the mouth; after death the stomach and upper part of the intestines were found uniformly distended with the same fluid.

Upper Bedford-place, W.C.

#### ON THE IMPORTANCE OF CONTINUOUS EXTENSION AFTER TENOTOMY IN CASES OF CON- GENITAL TALIPES, WITH TARSAL DEFORMITY.

By FREDERICK CHURCHILL, M.B., &c.,  
SURGEON TO THE VICTORIA HOSPITAL FOR CHILDREN.

HAVING had "a run" of these cases of late in my hospital practice, a brief record of the line of treatment adopted will perhaps tend to elucidate some of the difficulties experienced in obtaining permanent good results after division of tendons. Not only is it necessary that the distorted limb be placed in its rightful position by the division of parts, whether tendon or fascia, that hinder by abnormal contraction the extension of the foot, but far more important is the maintenance of the limb by continuous extension in that exact position which it is intended ultimately to assume. By forcible manipulation under chloroform many of the fibrous bands and interosseal ligaments which had helped to keep the limb in a wrong position can be stretched or divided, and the astragalus brought up to its normal position under the articulating surface of the tibia. Care, of course, must be taken so to manipulate the bones as to preserve the double arch of the tarsus. I am not one of those who think we can effect much without the division of tendons, nor do I place much faith in Scarpa's shoe as a means for counter-extension. It is fortunate that with better educational advantages and improved means of transit, parents are finding their way to hospital at an earlier period than formerly. The district surgeons, too, though well able in many cases to perform these operations, are finding out the advantage of early treatment, and the benefit to be derived from sending their patients to hospital towns, where skilful and patient continuous nursing as an adjunct to special surgical treatment is now valued and appreciated. I cannot too strongly protest against the folly of depending upon complicated and expensive mechanical appliances which fail to keep up continuous extension, though designed for that purpose. By adding weight to the already impoverished limb they rather increase than diminish the deformity. To see the children parading the streets, their limbs encased in iron, with the idea that in some unexplained way the distorted limb will come straight, is only equalled by the credulity of the mother who, when told that iron was good for a rickety child, ordered its limbs to be encased like an ironclad, with a sailor suit to match. When the deformity has become so marked that the child is accustoming itself to walk upon the sides, instead of the soles, of the feet, the joint surfaces

have been so moulded by the altered position of the foot, and the tendons have become so rigidly contracted within their sheaths, that to rectify such malposition needs great care and assiduous treatment by continual pressure in the direction required to rectify the deformity. It cannot be supposed that any instrument maker, however large may be his experience, and however skilful he may be in the manufacture and adjustment of appliances, can be so acquainted with the physiological processes of repair and methods of accommodation during the period of growth as to be able to arrange for all the little niceties needful for keeping up continuous extension. As a fact, the parents too often live within a charmed circle of their own ignorance. Scarpa's shoe, with all its screws and straps, and purchased at a somewhat prohibitory price to many, presupposes to the uninitiated a guarantee of its hidden powers for self-adjustment.

As regards division of tendons, I find that the tendo Achillis requires division in the great majority of varus deformities, simply because the gastrocnemius pulls the foot inwards as well as backwards during the flexion of the foot. The broad insertion of the tendon into the os calcis and the solid sheath encasing it permits of free division without absolute separation of all the attachments. By careful bandaging of the foot and leg the leverage obtained by the extensor muscles is to a great extent restored. As soon as all muscular impediment to the rectification of the foot is removed, there remains a considerable amount of distortion from the paralysed state of the extensor muscles. To obviate this I carefully apply a plaster-of-Paris bandage over a flannel "protective," bringing the foot up into its proper position by very firm manipulation, and keeping up this extension until the bandage has "set." By this means I succeed in procuring rigidity of appliance together with liberty for muscular effort. By galvanism and friction of the extensor muscles the tendons contract, and after three or four renewals of the plaster-of-Paris encasement the foot generally regains its normal position during the process of growth and development. Occasionally I fit a piece of webbing round the metatarsal bones and attach to the outside of it a length of solid elastic. The proximal end of this may be passed through a clip fixed to a garter below the knee. Continuous extension will in this way effect considerable rectification of the distorted parts. It will often be found useful with older children who are able to walk, and who have not such pliable and easily-moulded feet as young infants. I generally persevere for months with the treatment, and seldom require any mechanical appliance, not even in those extreme cases where the astragalus almost touches the ground.

Cranley-gardens, S.W.

#### FATAL CASE OF POISONING BY ERGOT OF RYE.

By A. DAVIDSON, M.B., &c.

On Saturday, June 3rd, about 4 P.M., I was called to see M. M—, aged twenty-eight, lately a hospital nurse. She was said to have "burst" a bloodvessel. On entering her room I observed a basin of reddish-brown pulaceous matter, said to have been vomited by the patient about 8 A.M. I was informed she had vomited something like it a few days previously, and, complaining of lumbar and arthritic pains, had expressed a fear that she was going to have rheumatic fever. Late on the previous evening she had passed a very hard motion, and a quantity of urine which looked like blood. About the same time, also, she had vomited half a pint of blood. During the evening and morning she gradually became worse.

On my arrival the face, eyes, neck, and upper portion of chest were intensely jaundiced. The intensity of the jaundice diminished from above downwards, till at last it disappeared altogether. She had a pair of genuine "black eyes." The rest of the body had a natural appearance. The expression was anxious, and the general condition maudlin. Occasionally fits of stupor and of apathy ensued. There was no alcoholic odour, but during the evening a distinct etherish smell could be perceived. The lips were slightly swollen, and covered with dry black blood. The tongue was also slightly swollen, dry black blood covering

the base and middle, whilst the edges and tip seemed of darker hue than natural, although moist. She lay chiefly upon her right side. The skin was pale and cold, but, although the thermometer only registered 96° in the axilla, the temperature there seemed about normal. The pulse was most peculiar. It seemed to indicate its presence to the finger, and disappeared before I could judge of its character; counting it was impossible. The respiration was noisy and laboured, and 48 per minute. Thirst intense; appetite gone. She swallowed with ease. The bowels had not acted since the preceding night, nor had she passed any urine. There was decidedly harsher breathing at the base of the right lung than elsewhere. The action of the heart was as peculiar as the condition of the pulse. The area and force of the cardiac pulsation were both increased, whilst the impulse against the chest walls was of a distinctly rolling character. I carefully counted the rate, and found that 160 cardiac cycles were completed in a minute. The sex, age, appearance of patient, and of vomit, immediately suggesting not only poisoning but a motive, I examined the breasts and found milk in them.

The patient volunteered no information, but, on being questioned, admitted having taken "two handfuls" of ergot, and also that this had been going on for several months. Subsequent events and the post-mortem examination showed that she had been taking the liquid extract for several months, and had quite recently taken two handfuls of the powder, not infused. The case seemed utterly hopeless; the exhaustion, hæmorrhage, and chronicity forbade the use of either stomach-pump or an emetic; and antidotes seemed equally useless, so I reported the matter to the police.

For my own protection I decided to call in Dr. Carter, a neighbouring consulting physician. Before I left a distinct uterine contraction occurred. The consultant recommended liquor chlori as an antidote, and it was decided to accelerate labour as a possible means of discharging the force of the poison through an active uterus. At 7.30 I introduced a No. 8 bougie-à-boule with great ease, but had to reintroduce it at 8.30, as she had removed it in one of her many paroxysms. At 9.15 the os uteri admitted one finger, so I introduced Barnes's smallest bag. I did so with ease; and twenty minutes later, finding the os less firmly encircling the bag, I removed it, and the membranes immediately followed. I ruptured them, and the head having presented, with little difficulty seized a foot. (Shortly before this brandy was given, but for the first and last time it regurgitated through the nose.) Whilst attempting to bring down the foot the breathing became easier and slower, until, just as I was about to deliver, it ceased altogether. Shortly before death the respiration was 56 per minute, and from 6 P.M. the pulse could be felt at all. The stupor had gradually deepened, but every now and then paroxysmal movements would occur whilst the patient would sit up in bed. She understood what I said to her occasionally, and was always obedient.

Thirty-two hours after death I made a post-mortem examination. The body presented much the same appearance as during life, save for the welling out from the mouth and nose of a greyish-black and gritty matter, which was very fluid. The body was well nourished. Greenish streaks were becoming visible on the abdomen. Cadaveric rigidity was passing off. The brain was remarkably firm, and perfectly free from hæmorrhage. None of its membranes seemed diseased, although it appeared rather looser in the cranial cavity than natural. The temporal artery bled profusely in making the preliminary incision through the scalp. In opening the abdominal and thoracic cavities an enormous quantity of fat was exposed, and embedded in it could be observed innumerable small hæmorrhages. The peritoneum was also covered with these hæmorrhages, and the bowels were everywhere in the same condition, besides being extensively bound down by adhesions. The abdominal cavity contained a very large amount of blood, and this rendered the detection of ascitic fluid impossible. No large vessel was ruptured so far as could be seen, the hæmorrhage being seemingly the result of an enormous number of small vessels having ruptured. The blood was fluid. The diaphragm was arched. The liver did not seem altered in size, but on section it was dry, bloodless, waxy-looking, and of a slightly dirty yellow colour. It was easily lacerable. The spleen seemed rather smaller than usual, and, on section, blood of a dirty red colour oozed copiously from it. The kidneys were enlarged, pale, and waxy-looking, and their capsules easily separable. The stomach exhibited ruptured vessels

in its walls, and contained a considerable quantity of the same fluid as came from the mouth and nose. The bowels were in the same condition. The bladder was quite empty. The uterus was about the size of an adult head. Its walls were stained all over with dark effusions, and on opening its cavity a fœtus of about five months became visible. There was neither liquor amnii nor blood in the uterine cavity. On removing the ribs the pleura was found non-adherent, but the lungs presented a remarkable appearance. They were rather anæmic, and this gave them a steel-grey appearance. On this as a ground were scattered innumerable irregular dots of the size of a small pea. These were hæmorrhages. The right lung was especially congested at its base. The heart was enlarged, having a large quantity of fat on its anterior wall and sides externally, but the valves were healthy. Its cavities were practically empty.

Brighton.

### A CASE OF MORPHIA POISONING BY HYPODERMIC INJECTION; RECOVERY.

By PHILIP E. HILL, M.R.C.S.,  
SURGEON TO THE CRICKHOWELL DISPENSARY.

EDWARD C—, a gardener, aged forty-eight, was admitted as a patient of the Crickhowell Dispensary on the 1st of August, suffering from mitral valvular disease with ascites. He had for some time past been under treatment, and for several days complained of severe abdominal pains, for the relief of which chloral hydrate alone and in combination with bromide of potassium had been tried, with little or no benefit.

On my visiting him at 11.30 on the morning of the above date, I found him in great agony, in which condition his wife informed me he had been during the greater part of the previous night. He implored me to do something for his relief, saying he could endure the suffering no longer; and as I happened to have my hypodermic syringe in my pocket, I introduced into his arm four minims of a solution of acetate of morphia (strength one grain in twelve minims). I then left him.

About 4.30 P.M. I received a message from his wife informing me that her husband was still asleep and snoring, and that she could not awake him. I at once started for his house, and found him, to my astonishment, in a condition of deep coma, from which I was unable to rouse him. The face presented a ghastly hue; the lower jaw had fallen; the lips were livid; the eyelids were open, the pupils contracted to a pin's point and perfectly insensible to the stimulus of light; the extremities were cold, and the surface of the body bathed in a cold sweat. Respiration was laboured, slow, and stertorous, but the pulse remained unaffected.

I immediately tried to rouse my patient by artificial respiration, flagellation with a wet towel over the face and chest, mustard applied to the nape of the neck and calves of the legs, with turpentine over the cardiac region, and, failing to administer coffee into the stomach from his inability to swallow, injected a strong solution of it into the rectum. Hot water bottles were also applied to his feet and body. These remedies were persevered in for some hours, when, to my gratification, consciousness gradually returned.

My friend Mr. Evan Parry, for whom I had sent, now fortunately arrived—for by this time I was getting exhausted from the combined effects of anxiety and my efforts to restore animation—and assisted me in carrying out the treatment. Our patient was particularly anxious to be left alone and allowed to sleep; but our efforts were unremittingly persevered in until 2 A.M., by which time the pupils had become almost natural, and the strong desire for sleep passed away. On my visiting him at 10 A.M. on Aug. 2nd he had completely recovered from the effects of the morphia, and was in no way the worse for its administration.

Remarks.—From the appearance of the patient when first seen I could only arrive at an unfavourable prognosis, which was concurred in by Mr. Parry on his arrival, but I cannot understand how such a dose as one-third of a grain of morphia, even when administered subcutaneously, and that after other sedatives had been tried without effect and time allowed for their elimination, should have given rise to such alarmingly poisonous results, for one would have

imagined that the great pain which was present would to some extent have resisted the influence of the drug. Was the exalted action of the salt due to the cardiac mischief, or might it not be more properly attributed to the idiosyncrasy of the patient, especially as the heart's action was in no way seriously interfered with? I can vouch for the accuracy of the strength of the solution, as it was the same I have always employed, and within the last month injected eight minims of it in divided doses, with an interval of four hours, into the arm of a gentleman suffering from persistent vomiting.

I cannot conclude this imperfect report without gratefully acknowledging the kind co-operation of Mr. Parry during this, to me, particularly distressing and anxious case.

Crickhowell.

#### GUY'S HOSPITAL.

##### TWO CASES OF CANCER OF THE RECTUM.

(Under the care of Mr. BRYANT.)

**CASE I. Excision of Rectum for Cancer; Severe Suppuration; Erysipelas; Relief.** (From notes taken by Mr. Manley).—Sarah H—, aged forty, was admitted on Nov. 26th, 1881, into Lydia ward. She was married, and had had nine children, the youngest of which was eighteen months old. Her labours had always been troublesome. Four years before admission she first noticed that she passed a little blood per rectum, and her bowel came down, but was replaced, and caused her no further trouble. During her last labour (an unusually severe one) she again passed blood from the rectum, and her bowel again came down. It was returned, but she felt a constant desire to pass motions, and these, when passed, were mingled with froth, slime, and blood. From that time she constantly had the same trouble with her rectum, and had alternate periods of relaxed bowels and constipation.

On Nov. 29th, under chloroform, she was examined. The finger could be passed beyond a zone of ulceration in the rectum. The posterior wall of the vagina was puckered and evidently infiltrated. It was decided to excise the rectum, and the patient was accordingly carried to the theatre. She was placed in the lithotomy position, when a small carcinomatous outgrowth protruded from the rectum. The vagina was examined by a speculum, but no definite disease was made out. An incision was made from the anus backwards in the median line for about an inch. The finger was introduced into the wound and passed round so as to completely isolate the rectum. The tissue between the rectum and vagina was then divided with scissors. The transverse perineal arteries were divided and twisted. Two lateral cuts were then made in the wall of the vagina dividing the mucous membrane and connective tissue; two arteries were ligatured. The posterior wall of the vagina was then divided with the scissors about an inch up and left in connexion with the diseased bowel. The diseased mass being completely isolated, the healthy bowel was fastened with ligatures all round. The scissors were then introduced into the rectum, and the wall of the bowel divided through the growth. On commencing to divide the diseased portion from the healthy part, the middle hæmorrhoidal artery was divided and ligatured. The growth was then completely removed without further hæmorrhage. The posterior incision was united by three sutures. The rectum was then sewn to the perineum, and in front to the corner of the vaginal flap made at the commencement of the operation. About half the divided sphincter was left. A drainage-tube was inserted between the rectum and vagina. The piece of bowel removed was about an inch and a half long, and much thickened. The inner surface was wholly infiltrated and fissured.

The patient was easier after the operation, but on the

early morning of Dec. 1st she was wandering and irrationally. The wound was, however, doing well. Next day the skin was hot and moist; there was a bright flush on either cheek. Tongue furred, but moist; pulse quick and soft.

On Dec. 5th the urine was slightly albuminous, breath fetid; and on the 13th an abscess to the left of the coccyx was opened. Next day the left buttock was swollen and red. A blush of erysipelas extended over the skin outwards and downwards. On the 16th erysipelas was disappearing. The edges of the wound were hard, and this hardness extended over the left buttock generally. On the 27th the cicatrix of the old abscess was opened, and about six drachms of pus (foul) came away.

On Jan. 3rd the hardness of the buttock had disappeared, and a fortnight later about an ounce of pus came from the cicatrix. On the 20th there was still a slight thin discharge from the wound in the buttock. On the 29th there was redness about the wound, and the woman had a rigor on the previous evening, lasting about half an hour. After this there was decided improvement.

On Feb. 7th she passed her motions fairly regularly, but they were hard. On the 9th the erysipelas was gone. On the 11th she seemed pretty well and comfortable. On the 22nd there was no sphincter power, and the incontinence gave great trouble. Between the anus and vagina was a fold of mucous membrane, which partly separated them. The sinus was closing. The aperture into the rectum admitted two fingers easily, and perhaps more. She had some diarrhoea. She had improved in appearance. She was discharged relieved.

From Dec. 1st to the 27th the temperature varied from 100° to 105° 8', this, the highest, being reached on the evening of the 14th. From Dec. 23rd onwards the temperature ranged between 98° 2' and 102°, though for the most part it was nearly normal. On the evening of Feb. 3rd there was a sudden rise to 104° 2', but next morning the temperature was normal again, and continued so.

**CASE 2. Cancer of Rectum in a boy aged fifteen; Colotomy; Relief.** (From notes by Mr. Henry Gard).—Samuel R—, aged fifteen, of R.W., was admitted on Dec. 20th, 1881, into Job ward. In the previous August he experienced great pain in defecation, passed a little blood each time, and about this time he began to feel severe lancinating pains. At first it was thought he had dysentery, and he was given suppositories, and took quinine and chemical food. Subsequently a growth in the rectum was diagnosed, and he was sent to England to be operated upon. He had at times passed a fortnight without alvine evacuation, and for a month before admission he had constantly had to use castor oil. When admitted he had not had a motion for six days.

On examination of the rectum a large growth, occupying the whole circumference of the bowel was discovered. The tip of the finger could just touch the lower end of the band, but the upper margin could not be reached. The mass was hard, and presented a sharply-marked edge to the finger. The growth appeared fixed in front and behind. Morphia and opium were given to relieve pain.

On Dec. 30th colotomy was performed. Nothing but colotomy could be suggested. No difficulty was experienced in the operation in Mr. Bryant's usual way. A healthy motion passed directly the intestine was opened.

On Jan. 1st he complained of pain in the stomach, but was easier after the operation. There was a thick discharge from the anus. On the 4th he complained of pain in the rectum sufficient to keep him awake. On the 7th the stitches were taken out; the wound looked healthy. Patient constantly required injections to enable him to sleep. On the 19th, at 5 P.M., a discharge of sanious pus, sometimes thick and sometimes thin, from the rectum appeared, and there was great pain at the seat of the disease. On the 24th he complained of great pain in the hypogastric region. The abdomen was hard and distended. Considerable pain in the rectum. On the 26th patient got up, and next day he was free from tenderness over the abdomen. The wound looked healthy. The rectum was washed out with glycerine and water, and some of the liquid came through the artificial anus. On the 28th he was in considerable pain, but was relieved by an injection.

On Feb. 8th he left the hospital with a healthy artificial anus. He still suffered from much pain in the rectum, and had a free discharge of pus. Took out with him one dozen morphia suppositories.

For a few days after the operation the temperature ranged from 93° 6' to 101° 4'. It then became normal and continued so.

The boy died exhausted in the middle of April, 1882.

## NORTH STAFFORDSHIRE INFIRMARY.

## REMOVAL OF ENTIRE UTERUS, LEFT OVARY, AND FALLOPIAN TUBE.

(Under the care of Mr. W. DUNNETT SPANTON.)

FOR the following notes we are indebted to Mr. W. T. Clegg, house-surgeon.

Elizabeth J—, aged forty-three, spare but not cachectic, married, but had no children, was admitted into the North Staffordshire Infirmary March 25th, 1882. For some months previously she had experienced pain in the back and uterine region, with frequent desire to micturate. Menstruation had been regular, not profuse, but attended with great pain. The pain had been so intense as to render life almost intolerable, and she was anxious to submit to any measure likely to afford relief from it.

When examined, the uterus was found to be quite movable, enlarged, exceedingly hard to the touch, and nodular. The cervix was almost absent, the uterine tissue with the internal os being felt, as it were, through the opening of the upper part of the vagina. The sound passed three inches into the uterus, causing much pain. All other organs appeared free from disease. A consultation was held, and it was found that all ordinary methods of treatment failed to mitigate the pain, and the patient was desirous to have anything done which would afford a prospect of relief. On March 30th, under the influence of ether, the uterus was removed. An incision through the linea alba of about four inches was made, the small intestines carefully withdrawn through the wound and wrapped in hot sponge cloths, and then a silk ligature passed through the fundus uteri, which was found of great service in lifting up the uterus. A silk ligature was then passed through three portions of each broad ligament, after the manner of Freund, so as to include the ovarian artery, the round ligament, and the uterine arteries. Each broad ligament was then divided near the uterus on the right side, but external to the Fallopian tube and ovary on the left side, and the vaginal roof divided at its junction with the uterus, which was then removed with the left ovary and Fallopian tube attached. The uterus after removal was found to contain several hard nodules of myoma, embedded in the muscular wall. The cavity was three inches in length; cervix absent up to internal os uteri, being entirely eroded by infiltration of epithelioma, which was, however, limited to that part. It appeared to be an example of so-called liquefactive epithelioma, in which the tissues melted away as it were, leaving only microscopic evidences of its true character. The microscopic examination of the tumours showed the ordinary appearances of myo-fibroma, but with more round cell infiltration than is usually met with, approaching a round-celled sarcoma in its character. There was nothing abnormal about the Fallopian tubes or ovaries. There was no hæmorrhage, certainly not more than an ounce of blood being lost throughout. Two small branches at the lower part of the broad ligament were secured with catgut for precaution. A large glass drainage-tube was inserted into the vagina, quite filling up the supra-vaginal opening, and the abdominal wound was closed by ordinary silkworm-gut sutures, and dressed with eucalyptus gauze. The whole operation—performed under the eucalyptol spray—from the time the patient was brought into the room to being finally arranged in bed occupied less than an hour. In the evening of the same day the patient seemed comfortable; had no sickness; about a pint of clear urine had passed through catheter. Temperature 100° 2'; pulse 102. At 12 P.M. the temperature and pulse continued the same. At 4 A.M. next morning (March 31st) the temperature was 100° 4'; pulse 93. The patient had passed a good night. About a pint of clear urine passed by catheter. There was not much pain, but considerable distension of the abdomen. There was a slight sanguineous discharge into the vaginal tube, requiring a fresh plug. Temperature 99° 4'; pulse 102. During the day the patient complained of pain in the abdomen, for which morphia suppository was employed; but restlessness and increasing weakness ended in death at 3 A.M. on April 1st.

*Post-mortem examination, next day.*—The abdominal wound had healed throughout the deeper parts. The coils of the intestine were distended and sticky with recent lymph. The pelvic cavity was dry and clean, and there

was no trace of hæmorrhage. The silk ligatures were firm. The ureters were quite free, on the left side more than an inch, and on the right not more than half an inch to the outer side of the lowest ligature.

The result of this case, although not successful, is very satisfactory, as showing that this operation may be performed (1) without any extraordinary difficulty, (2) without hæmorrhage, (3) without danger to the neighbouring parts, and (4) with a fair chance of eradicating the disease as completely as in operations for malignant disease in other parts of the body. The recuperative powers of the patient appear to be the one element of great uncertainty in the success attending the operation.

## CUMBERLAND INFIRMARY, CARLISLE.

## CHLOROFORM FRIGHT IN A CASE OF ANCHYLOSIS OF ELBOW JOINT.

(Under the care of Dr. H. A. LEDIARD.)

FOR the following notes we are indebted to Dr. Leith Waters, house-surgeon.

M. B—, aged nineteen, a stramious-conditioned girl with enlarged flabby tongue, on whom excision was about to be performed, was put under the influence of chloroform on Sept. 11th, 1882, and had taken from about two to four drachms. The knife had not touched the skin, and the spray had just begun to act over the parts when, without any stertor or warning note, the breathing, soft from the first, became imperceptible to the ear under the swish of the spray, and then completely stopped. About the same time, or perhaps before the stoppage of respiration, the face became markedly pallid, while the pulse, though weak and irregular, was felt in the radials throughout the period of fright, which lasted for about half an hour. Artificial respiration was at once begun—first by the direct, then by Silvester's method, and was kept up with momentary stoppages during the period. The windows were thrown open, and the chest, with shoulders raised and head thrown back and lowered, was well flipped with cold-water towels, &c. The faradaic current, one pole over the phrenic and the other over the epigastrium, was kept up at intervals during the latter part of the period. This brought on thorough and immediate action of the diaphragm and the abdominal muscles of expiration, greatly aiding the now almost restored efforts at voluntary respiration.

The operation was postponed, and to be next time anaesthetised by ether. A prolonged drowsiness followed the restoration of breathing, and during this period stimulants were administered, the patient being at the same time prevented from falling into torpor by the assiduous stimulation of the face and chest by cold water and by the kneading of the ribs.

A careful examination of the heart after the patient had been removed to bed showed the existence of some presystolic roughness in the mitral area. In the urine there was a good trace of albumen, but no sugar. She had an attack of scarlet fever when ten years of age. There is no history of rheumatic fever or pain, but her father died of heart disease at the age of fifty-eight. It is worthy of note that three days previously the patient had taken chloroform very well, it having been administered in order thoroughly to examine the joint and break down adhesions if possible.

Sept. 18th: Patient was carefully and successfully placed under the influence of ether, and the joint excised by a single longitudinal incision. Firm osseous anchylosis was present, which did not, however, extend to the radio-humeral articulation. During the insensibility the breathing was good and audible; but the pulse sank to about 56 for a short time.

The administration of ether was kindly watched by Dr. Barnes, physician to the infirmary.

**A RESCUE BOAT-RACE.**—At the Clevedon Regatta on Saturday last, a novelty was introduced in the shape of a "Rescue race." The idea was originated by Dr. Richardson, F.R.S. (who is staying in Clevedon), who gave the first prize of £1 ls., Mrs. Richardson giving the second of 10s. 6d. The whole of the competing boats had to be stranded high and dry upon the beach, and at a given signal the men had to get them launched, and then proceed to try to pick up one of two objects, representing drowning men floating about three-quarters of a mile out in the bay.—*Bath Mercury*, Sept. 26th.

## Reviews and Notices of Books.

*Schematic Anatomy; or, Diagrams, Tables, and Notes, treating of the Association and Systematic Arrangement of Structural Details of Human Anatomy.* By W. P. MEARS, M.B., co-Lecturer on Anatomy, Supervisor of Dissections, and Medical Tutor at the Durham College of Medicine, Newcastle-upon-Tyne. London: Baillière, Tindall, and Cox. 1882.

THE aim of this work is decidedly novel. Students and lecturers have always made use of diagrams and notes of associated facts in learning or teaching the numerous details of human anatomy, but we have never before seen such an ambitious attempt at "aids to memory" as is here presented to us. The bones, ligaments, muscles, vessels, and nerves are tabulated and delineated—we cannot say described,—and we are promised the viscera in a second volume. The student is recommended to display the facts on the dead subject in the first place, and then to fix them in his memory by means of a corresponding schema or diagram. If there were any real relationship between the dissected part and the mathematically-drawn figures in this work, it would be a valuable addition to the text-books used by the student, but the more elaborate the schemata and diagrams become, and the more closely the associations are urged, the more apparent are their divergences from the true details of human anatomy. In the sketch of the femur, facing page 36, the relative attachments of the muscles are inaccurately shown, for the insertion of the adductor longus is made to correspond in extent with the origin of the femoral head of the biceps, and more space is allotted to the plantaris than to either head of the gastrocnemius. The diagrams of some of the plexuses are most extraordinary, and representations by exactly similar outlines of the inferior dental, gustatory, glosso-pharyngeal, and hypoglossal nerves and their branches (p. 176), must confuse the student rather than diminish his labours. The book has evidently caused Mr. Mears much trouble and thought, but an insistence on the constant use of the scalpel and forceps is the only true method of teaching anatomy, and a few diagrams and tables constructed by the student himself from his own dissections will remain much longer in his memory than the elaborate and somewhat complicated system drawn up by the author.

*The Tissues and their Structure.* A description of the Elementary Tissues of the Human Body. By A. S. KENNY, M.R.C.S.E., Senior Demonstrator of Anatomy in King's College, London. London: David Bogue. 1882.

THIS small work of 120 pages contains a very clear and accurate description of the elementary tissues and their functions, and is especially adapted for beginners in histology. It will enable them to form some conception of the general structure and functions of the tissues which they are practically investigating, and should be used with the text-book, which directs them how to proceed with their manipulations. The book is well printed, and the illustrations, many of which are quite new, are excellently drawn.

*The Compend of Anatomy.* By JOHN B. ROBERTS, A.M., M.D., Lecturer on Anatomy and on Operative Surgery in the Philadelphia School of Anatomy, &c. Second Edition, revised. London: Henry Kimpton. 1882.

THE fact that a book has rapidly run through a first edition is a recommendation in its favour, but we entertain a great distrust of small works that assume to give concise statements of what is deemed essential to the student in human anatomy or any other science. This distrust is not removed by the volume before us, for all the essential details are contained in less than 200 pages. The necessary conciseness has been obtained at the expense of adequate description, for the only details of muscles and nerves which

the author gives are those which can be seen at a glance in a series of tables. It is announced in the preface that the statements and general arrangement of Gray have been followed, and this is evidently true, for the book appears to us to be merely an abridgment of that work, whilst many of the advantages and excellences of the latter are lost. The only novelty is a partial substitution of English names for Latin ones, and this is not always an unmixed gain—e.g., is "compend" a better word than "compendium"?

*Publications of the Association for the Advancement of Medicine by Research.* London: J. W. Koelkmann. 1882.

THE Association for the Advancement of Medicine by Research has issued its first batch of publications, consisting of four pamphlets. They are none of them new, but are reprints of addresses on the aims, methods, and purposes of scientific experiments on animals. We are glad that the Association has utilised the excellent address of Mr. Simon at the opening of the State Medicine Section of the International Medical Congress. This bears the title of "Experiments on Life," as fundamental to the science of preventive medicine, and sets forth in a most masterly manner the value and extreme economy of direct experiment upon living animals. Two other of the pamphlets regard the practical results to surgeons of vivisectional experiments; these are Dr. Humphry's short address at Ryde, entitled "Vivisection: what good has it done?" and Dr. McDonnell's address delivered before the Surgical Society of Ireland, entitled "What has Experimental Physiology done for the Advancement of the Practice of Surgery?" With the former of these our readers are familiar, as it has already been widely circulated among the profession, with whom it is judged to have but one failing—brevity. Dr. McDonnell's Address is an extremely useful one, and deservedly ranks with those already mentioned. No attempt is made to detail all the benefits surgery has derived from experiments on animals; reference is chiefly confined to their value in the study of anaesthetics, the introduction of the administration of potent remedies by hypodermic injection, the bloodless surgery now so generally practised, the arrest of hæmorrhage, and the treatment of wounds. The fear that performing or witnessing such experiments blunting the moral perceptions is shown to be entirely groundless. The fourth of this series of pamphlets is Mr. Wm. Bowman's Address in Surgery, read at Chester, at the meeting of the British Medical Association in 1877. The main topics of this address are the essential unity of the art, its dependence upon science, and the advantages of union and organisation for the promotion of common objects. Incidentally Mr. Bowman vindicates the right and duty of experiments on living animals; and this it is, we presume, which leads to the republication of this address at the present time, and in its present form. We congratulate the Association on so quickly setting to work, and on the choice it has made for its first publications, which we hope will be very widely read and studied. The best support the profession can give to the Association is to become apt pupils, to avail themselves of the opportunities afforded of obtaining thorough acquaintance with the part scientific experiments have played in the vast strides our art has made during the last century; and a wise distribution of their pamphlets among the more intelligent of the general population will also greatly aid the cause we have at heart.

*Die Parasitären Krankheiten des Menschen. I. Entwicklungsgeschichte und Parasitismus der Menschlichen Cestoden.* Von SIGMUND THEODOR STEIN. (*Parasitic Diseases of Man. I. Developmental History and Parasitism of Human Cestodes.* By SIGMUND THEODOR STEIN.) Lehr: Schauenburg. London: Trübner. 1882.

THIS handsome monograph upon the very interesting class of tapeworms is, as the title-page and introduction

inform us, but the first of a series of similar works dealing with the parasites of man that Herr Stein has in view. He intends to issue another part dealing in like manner with the nematode, trematode, and arachnid parasites; a third with the dermatozoa, epizoa, and epiphytes; a fourth with the protozoa, infusoria, and fungi. The present treatise commences with a brief historical introduction, in which the labours of von Siebold, Leuckart, and Küchenmeister are especially dealt with; but we fail to find any reference to English writers in this place. In justice to the author, however, it should be added that in the body of the work he shows himself fully acquainted with Dr. Cobbold's labours. The first chapter deals with the larval condition of tape worms, and is copiously illustrated with figures of mealy flesh and the cysticerci. Indeed, the whole volume is most fully adorned with engravings, in addition to fourteen large photo-lithographic plates at the end. The second chapter treats of the developmental history of the human tapeworm: first the characters common to *Tænia solium* and *T. saginata* (*T. mediocanellata*) are described, and then the differential points. Then comes a description of each of these worms in the adult form, followed by full and minute details as to the formation of the generative organs and the development of the embryo. The genus *Bothriocephalus* forms the subject of the third chapter; the same minuteness of description characterising the previous studies being also shown here. Of course, most of this chapter deals with the common form, *Bothriocephalus latus*; but a section is devoted to the rarer species, *B. cordatus* and *cristatus*. In the fourth chapter we have descriptions of such rarer *tæniæ* as *T. nana*, *T. flavopuncta*, *T. cucumerina-elliptica*. The fifth chapter is entitled, "The influence of tapeworms and their progeny on the human body, including therapeutical measures." The sixth chapter treats of the echinococci, and concludes the work. The following figures compiled from Davaine, Cobbold, Finsen and Neisser are interesting as showing the comparative frequency of hydatid disease in various organs:—Out of a total of 1862 cases, the liver was the seat of the parasite in 953, intestinal tract in 163, lungs and pleura in 153, kidneys, bladder, and sexual organs in 186, brain and spinal cord in 127, bones in 61, heart and bloodvessels in 61, and other organs in 158. The work bears evidence of considerable original research and an extended study of the literature of the subject.

## THE GENEVA CONGRESS.

### No. III.

As in the five sections no less than fifty-one questions had to be discussed, we are compelled to abandon the hope of giving even the briefest account of each of these interesting debates. Of the general meetings we have already given some account. They were not altogether satisfactory. The afternoon devoted to Professor A. Corradi's paper on the contagion of phthisis failed to elicit anything new. Various suggestions, however, were made. Dr. E. Valin, for instance, though inclined to believe in the contagious nature of the disease, remarked that the fact that animals inoculated with the bacillus of phthisis contracted the disease did not absolutely prove the susceptibility of man to this germ. Guinea-pigs would die of phthisis if shut up in the same room as a man suffering from this disease, without there being any inoculation. In any case, while on the Continent zymotic patients could not be isolated, it was much too soon to speak of the isolation of tuberculosis. Indeed throughout the discussion it was clear that grave doubts still existed as to the contagious nature of phthisis, and a strong feeling was manifest against isolation. The depressing effect of isolation hospitals would act almost as a

sentence of death upon the patients, according to Dr. E. Landowski's experience. Dr. Lubesski, delegate of the Warsaw medical school, thought that the clothes and beds were the most likely source of infection, and suggested researches as to the special character of the perspiration coming from phthisical patients. Another speaker inquired whether it would not be well to study the effect of sewer-gas and sewage on the vitality of the bacillus; as the prevalence of phthisis was more marked in districts where the drainage was bad, and general hygiene neglected. Dr. Leudet of Rouen gave the result of twenty-eight years' study of fifty-six families with whom he was intimately acquainted. In fifteen cases the husband, and in forty-one cases the wife, died of tuberculosis. Of the fifteen widows five ultimately showed symptoms of tuberculosis. This might encourage the belief in contagion, but one of the women had a rachitic deviation, another lost her aunt, and the third her sister from the same disease. Of the forty-one widowers, only three died of phthisis. Therefore, Dr. Leudet concludes that if marriage is a cause of contagion, the contagion is more frequent from the husband to the wife than from the wife to the husband.

After this discussion, Dr. Varrentrapp, medical officer of health for Frankfurt, gave a very interesting account of the school colonies organised in Germany for the purpose of sending the weak and poor children of large towns for four to six weeks to the country during the holidays. Guetlet's comparative tables are used to record the weights and measurement of the children at their departure and their return from these expeditions. The improvement was found to be on an average 1 kilo 300 grms. for the boys, and 1 kilo 480 grms. for the girls, and the average growth two centimetres. The remarkable point was that the good impulse given by this sojourn in the country continued after the return to town. The children also acquired habits of cleanliness and discipline, and the cause of education derived great benefits from this system. In Denmark it was the custom to send two or three children to board with an agriculturist, who took them for nothing in exchange for their labour. The railway and steam companies gave these children free passage, and thus 7000 children were able to escape for a little while the injurious effects of overcrowded towns. At Berne the school teachers were in the habit of taking thirty to forty children to the country, when special contracts were made with purveyors, and the authorities provided gratuitous conveyance. The Pastor Zillon, of Zurich, first started this idea, and now in twenty-two towns of Germany regular holiday colonies have been organised. Milan was the only other town that had followed the German method in the organising of these holiday colonies. The next general discussion related to the effect of altitudes on the health of patients, &c., when Dr. Paul Bert delivered the remarkable speech already mentioned in these columns. To his experiments on mountain sickness we should now, however, add his peroration, rich in speculative thought. Dr. Paul Bert having shown that the blood of animals living in low countries absorbs from 10 to 12 per cent. its weight of oxygen, whereas the blood of the same animals acclimatised at La Paz, some 12,000 feet above the level of the sea, absorbed from 18 to 20 per cent. its weight of oxygen, concluded with these words:—"Thus, therefore, when men or animals resort to high altitudes they become acclimatised in the course of a few generations. Their blood, being enriched by a larger proportion of hæmoglobin, is capable of absorbing a much greater quantity of oxygen. Such results are most consoling for the future of human races. You are all aware that astronomers menace us with annihilation, which, though in the far future, is none the less certain. They tell us that the central fire will gradually go out, that the air which surrounds us will ultimately reach the profoundest depth of the globe, and, the atmospheric pressure slowly diminishing, the moment will come when it will no longer suffice to maintain life. I do not wish to challenge these pessimist predictions; but their gravity is singularly attenuated by the considerations I have brought to your notice. What has happened to save the inhabitants of the Cordilleras will save our descendants. As the barometric pressure decreases their blood will alter in character, to harmonise with the surrounding atmosphere. The facility for absorbing the oxygen of the air will augment, and life

will continue to be possible long after the epoch when, according to calculations based on our present condition, the human race is doomed to die."

Dr. W. Marcet, F.R.S., also gave a very interesting account of his scientific experiences while mountaineering. He thought that cold and the rapidity of the ascension had a far larger share than is generally supposed in producing "mountain sickness," and had noticed that the southern or warmer side of a mountain was never so painful to climb. As a means of procuring oxygen, so necessary to combat the effect of high altitudes, he suggested chlorate of potash, for it was easy to carry, and liberates oxygen when in contact with the heat of the mouth. Cold corresponded with the lack of oxygen, and by careful experiments he found that his breath contained 19 per cent. less carbonic acid on the summit of a high mountain than at Geneva. With his assistant the difference had been greater—namely, 21·8 per cent. Dr. Marcet concluded, like all the other speakers, with the opinion that medium altitudes had a tendency to check phthisis.

At the final general meeting of the Congress a paper was read by Dr. Haltenhoff of Geneva, on the Prevention of Blindness. Though statistics were not complete, particularly those of countries where blindness was most prevalent, such as Russia, Algeria, Turkey, and Egypt, yet they might calculate that there was at least one blind person out of every thousand of the European population. This gave us about 330,000 blind persons in Europe, and the larger half of these cases might have been prevented. Fortunately an English philanthropic society had taken the matter in hand, one of its principal means of action being the distribution of short popular pamphlets full of practical, intelligible suggestions. Dr. M. Roth, the secretary of the Society for the Prevention of Blindness, had known how to rally the French hygienists to his cause, and at the Turin Congress it was resolved to make this a subject of discussion at Geneva. In the meanwhile, the English Society had decided to offer £80 for the best work, written in English, German, French, or Italian, on the subject. The speeches that followed, and notably an able oration from Dr. Roth, in which he calculated that the blind of Europe cost society 100,000,000 fr. to maintain, all went to prove that neglect in childhood and at the first outbreak of disease was the cause of the far greater number of cases of total blindness.

At the termination of this discussion, Dr. A. J. Martin, general secretary of the Paris Société de Médecine Publique, read the official report he had been requested to prepare on the Sanitary Exhibition, remarking that the Swiss law on patents had kept many exhibitors away. The report naturally partook of the general enthusiasm which prevailed throughout the Congress, but it was ably written, and Dr. Martin did venture to attack, at least, one or two faulty exhibits. This document has already been published *in extenso* in the Swiss and French papers.

There now only remained to decide where the next Congress should meet; and, in response to an invitation transmitted by Dr. van Overbeek de Meyer, it was unanimously resolved that the Fifth International Congress of Hygiene should be held at La Haye in 1884. Dr. van Overbeek de Meyer will be one of the principal organisers of the forthcoming Congress, and communications on the subject can now be addressed to him at the University of Utrecht.

Perhaps one of the most stirring incidents of the last sitting was the speech delivered by Dr. P. Bœner of Berlin, which, as it contains an invitation that some of our readers may feel disposed to accept, we will translate:—"A fatal destiny destroyed our sanitary exhibition on the 12th of May, just as everything was ready. The objects were all in their places, the catalogues printed; we were only waiting for the public. In one hour, as you are aware, all this labour was annihilated. But we have not lost heart; and our courage was revived by the cordial sympathy we received from all sides. Our misfortune was due to employment of wood for the building of the exhibition. Now, however, I have the joy of announcing that a new edifice has already been raised on the ashes of its predecessor, and that this time it is built of glass and iron, filled with new exhibits, some of which had not been sent on the previous occasion; and it is with a feeling of no small satisfaction that I have the honour of presenting to the Congress the programme of the new and resuscitated exhibition." At this moment the members of the Congress, anxious to manifest their sympathies, gave vent to the warmest cheers and applause. The

speaker, visibly moved, continued:—"Our exhibition, from purely practical motives, is not called international; but we will receive with gratitude anything of interest from whatever country it may come. In visiting Berlin, you will find something more than this exhibition of hygiene, which by its very nature is as international as humanity. By the side of the material interest in the exhibits, the sanitary works of the capital, you will meet a cordial, hospitable, and warm welcome." After a fresh outburst of cheers, and on the proposition of the President, the Congress passed a resolution expressing sympathy for the past and encouragement for the future. In this matter the French members of the Congress manifested a cordiality which showed how much devotion to a noble science can help to mitigate political and national antagonism.

## ROYAL COLLEGE OF SURGEONS OF ENGLAND.

It appears from the statistics of the College examinations, which are published in the new Calendar just issued, that during the official year ending Midsummer Day last, 46 candidates passed the first examination for the Fellowship of the College, and 61 were referred for six months; 21 candidates passed the final examination and were admitted Fellows, and 21 were referred for one year. For the primary Membership there were 1091 candidates examined, of whom 743 passed, and 305 were referred for three and 43 for six months. At the final examination for the diploma of Member 666 candidates were examined, of whom 343 passed; 56 passed in surgery, and during the year qualified in the other subjects,—making altogether 309 diplomas granted in the year; 69 candidates were approved in surgery, to qualify in medicine and midwifery; and 254 were referred for six months. During the year there have been three meetings of the Board in Dental Surgery, and 32 candidates have been examined, 28 of whom obtained the diploma.

The Calendar contains some interesting tables which accompanied the Report prepared for the Royal Commission on the Medical Acts, showing the number of registrable titles granted by the College during the five collegiate years from 1876-77 to 1880-81, ending on the second Thursday in July in each year, and the receipts from examinations and from other sources, and the expenditure in the several departments in the College over the same period. It appears that of the 300 honorary Fellows elected under the Charter of 1843 only forty-three are now living, Mr. James Moncrieff Arnott being the senior and Mr. Spencer Smith the junior Fellow of that batch. The total number of Fellows of the College now is 1186, of whom 586 were admitted after examination, and 600 by election.

Thirty-two deaths have been reported during the year, thirteen of which occurred at the advanced age of fourscore and upwards—viz., Michael Thomas Greenhow, of Leeds, eighty-nine; George Macilwain, of Harlow, eighty-six; John Flint South, of Blackheath, late President of the College, eighty-five; Henry John Gore, of Tunbridge Wells, eighty-five; Richard Thomas Gore, of Bath, eighty-four; James Luke, of High Wycombe, late President of the College, eighty-three; George Rawbone, of Tooting Graveney, eighty-three; T. Pollock, of Hornsey, eighty-four; George Sampson, eighty-five; Edward Greatrix, late of the Royal Horse Guards, eighty-two; Edward Doubleday, of Long Clawson, eighty-four; John Lonsdale Minshall, of Liverpool, eighty-one; and Price Blackwood Hallows, of Canterbury, eighty-one.

By the upsetting and breaking of the gig in which he was riding, Dr. C. C. Greig, of Fyvie, has, we regret to learn, sustained injuries of a serious, though, it is hoped, not of a dangerous character.

# THE LANCET.

LONDON: SATURDAY, SEPTEMBER 30, 1883.

Now is the time of preaching. At this season of the year parents, guardians, relatives, friends, teachers, and writers in the lay and medical press claim the privilege to lecture, caution, monish, and advise the medical tyro. Within a week the students assembled at the various medical schools scattered throughout England will have had sounded in their ears alternate notes of solemn warning and lively welcome; they will have been congratulated on the choice they have made both of a profession and school, harangued on the loftiness and nobility of their vocation, and flattered with the prospect of material and intellectual triumphs. They will have been told what scope their powers will find in the study and practice of medicine, and they will have received many a useful hint and suggestion as to how those powers may best be trained for their ultimate employment. The virtues of honesty, sincerity, diligence, perseverance, sobriety, truthfulness, and respect for those in authority will have been justly and becomingly magnified. In short, the novice will have been plainly told that if he should ultimately fail to reach the goal the fault will be his own.

It is an excellent practice thus to offer words of warning and of counsel to those who are about to enter the medical profession. It has been continued so long, and has received the sanction and approval of so many masters, that it must be salutary. At any rate, few have had the courage to declare its vanity. We at least have no disposition to question its utility; we would rather extend its application. It may be well to turn the tables for once, and take ourselves to task, and ponder some of the wise utterances prepared for students in our hearts. *Quis custodiet custodes?* Who shall admonish the teachers? The very thought savours of presumption.

The strictures upon students, on the one hand, and upon examiners on the other, during the last twenty years, have been neither few nor slight. The idleness, indifference, ignorance, and stupidity of students, have formed the staple of most of the official utterances of examiners, and have been echoed by teachers, while examiners in their turn have been freely charged with incapacity, incompetence, selfishness, and cupidity. Meanwhile the teacher has usually escaped. Few have ever ventured to carry criticism into the teachers' camp. It seems to have been tacitly assumed that the office of teacher is inviolable. Interference with his function has always been sharply resented and quickly checked. And yet it would be hard to maintain that the attainments of teachers have kept pace with the increasing requirements of examinations. On the contrary, the relations of medical education and examinations have been reversed. Students are now the slaves of the examinations; everywhere they are over-examined and under-taught. Anyone whose business or inclination may lead him to visit the examinations conducted by the various examining bodies—say the Royal College of Surgeons of England—will soon be convinced

that the majority of candidates exhibit a "plentiful lack" of education and training. They are not devoid of knowledge, their memories have been fairly exercised, their answers often rise readily to the lips, and still it is obvious that with most of them the reasoning faculty is almost in abeyance. If memory should play them false, reason, so long neglected, finally refuses her aid. This implies defective training and preparation, the responsibility of which rests chiefly upon teachers. Candidates are not, as a rule, ignorant, but they are uneducated; they show no signs of having been taught the philosophy of things. Of empirical knowledge they have enough, and to spare. They are familiar with quite a host of isolated facts, but are unacquainted with the relation and connexion of these facts. They have been instructed, but not trained. Information has been mechanically imparted, and is given out again in like manner. This is the fallacy underlying most educational schemes now-a-days. Many conscientious teachers fall into the error of mistaking instruction and the imparting of information for education, whereas the evil is that the student is taught too many things—*multa* instead of *multum*. The late Dr. LATHAM saw the danger in his time. "In our day," he said nearly fifty years ago, "there is little fear that students will be spoiled by the recommendation of their instructors to be content with a scanty knowledge, and trust to their own sagacity for the rest." A life-time will not suffice for the acquirement of every accomplishment which might be mentioned as subservient to the medical profession. Dr. ROTHÉ at the end of the last century published a select catalogue of medical works, every one of which he considered as good and useful for the medical student and practitioners. Of this formidable list THOMAS YOUNG said that a person "beginning with languages might spend the first ten years of his studies without getting much further than the 'Chinese,' and twenty more before he came to those of the 'Bohemians' and 'gipsies'; to say nothing of the 'logical, metaphysical, moral, political, statistical, technological, agricultural, mathematical, geographical, chronological, genealogical, heraldic, diplomatic, numismatic, and historical' works which are to follow, before he enters on chemistry and anatomy." This is, perhaps, the *reductio ad absurdum* of medical education, and yet it is not much more impracticable than many of the schemes of some modern reformers.

Improvement in medical education, therefore, must begin with the teachers themselves. The teacher must be made to feel his responsibilities more acutely. The art of teaching is difficult, but it may be acquired by every earnest mind. It is not enough for a teacher to be punctual, he must be industrious and, above all, scrupulously honest. The process of education is slow, tedious, and often painful, and demands patience, perseverance, and restraint. The result is so remote, and so uncertain, that the consciousness of having honestly done his best may be the only reward the teacher may receive for all his pains, but the reward is precious.

WE have at least one thing for which already to be thankful to the Royal Commission, and that is for eliciting from the very highest authorities the best defence of the system by which the Fellowships of the Scotch Corporations,

particularly that of the Royal College of Surgeons, are bestowed. We ourselves are largely responsible for directing public attention to this question. We admit feeling the deepest interest in it, and we will further confess to being utterly dissatisfied with the defence put forward in the name and at the request of the Edinburgh College. There is this one thing good, however, in that defence. It was made by Professor SPENCE, and in perfect good faith. If the defence of such a man does not carry conviction or bring back respect, the system must be considered incapable of justification, and fit only for abolition. The Royal Commissioners seem to be entirely of our opinion. They, in the 54th and 81st paragraphs of their Report, say as follows:—

“54. We do not propose to interfere with the present powers of Universities or Corporations to confer their titles, with or without examination. We think, however, that, in the case of persons entitled to be registered, a discretion should be given to the Medical Council to permit these titles to be registered or not, as they see fit.

“81. We think that a column should be set apart in the Register for the registration of the higher titles recognised by the Medical Council as indicating substantially higher medical qualifications than are required for a licence.”

The authorities of the Edinburgh College know as well as we do, that under such clauses, with a reformed Medical Council, the present Surgical Fellowship of the Edinburgh College could not be registered in future.

But let us have the College's defence of its present Bogus Fellowships. This will be found in substance in the evidence of Professor SPENCE, published by us last week. Mr. SPENCE says essentially three things—1st, that the title of Fellow does not imply a qualification to practise or a higher degree, but only that the Fellow is an associate of the College; 2nd, that to deny the Fellowship, except on terms of extra study and time, is to saddle a young man with expense in a way that is not right; 3rd, that under the examining system the College was in a state of marasmus—“dwindling away.” It will be seen shortly that the adoption of the non-examining, or, as we may call it, the purchasing system, operated on the “dwindling” College as cod-liver oil on a tabetic patient. But let us examine the points of Mr. SPENCE's defence of the system in detail, for it must be remembered that the College did not always sell its Fellowships, but that, until the date of its present charter, 1851, it acted as its sister Colleges do, and gave its Fellowships on terms of examination.

It is alleged that the Fellowship is not a qualification to practise or a higher degree, but only a title of association. We demur to this representation altogether. It is true that the Fellowship is not given to one who is not already licensed to practise, but his licence may be of the lowest order, and on the strength of this, with the addition of the most easily obtained testimonials, he is admitted by a ballot vote to the Fellowship. This Fellowship once obtained, no matter how—and here is the serious and substantial error in the College's representation,—it becomes an actual qualification for some of the most responsible parts of medical duty. It is a *sine quâ non* in regard to the surgical appointments, for example, of the London hospitals; and it is a matter of notoriety that the Fellowship of Edinburgh is taken, not from any interest in the affairs or government of the College, but as a qualification for hospital appointments. Is it not

misleading, to the public at any rate, to say that this is not a qualification, and that it is not a higher degree? Can there be a more unfair use of a high title than to disconnect it from the examinations with which in the sister Colleges it is associated—unfair to the public who are misled by it, and unfair to the great bulk of practitioners who, with their ordinary titles, gained by passing respected examinations, are placed at a discount? We maintain, then, that the Fellowship is virtually a qualification, and that it is very unfair to grant it on the strength of a mere licence to practise, backed by testimonials which anyone can get who has shown reasonable compliance with the Decalogue. Is there any more force in Mr. SPENCE's argument, that to withhold a Fellowship, except on terms of extra study and education, is to hinder a young man's progress, and is going beyond the right of Corporations? Does the Edinburgh College itself not hinder a young man by saying that he shall not have the Fellowship till he is twenty-five, and that he shall not have it till he has paid a large sum for it? Mr. SPENCE condemns one part of his argument by the other part. He says that a young man is licensed to practise apart from the Fellowship. How, then, is he hindered except in regard to those appointments for which, as we have shown, the Fellowship is an actual qualification, which Mr. SPENCE says it is not. As Mr. SPENCE's first two arguments crumble to pieces on close handling, the strength of his convictions must be looked for in his third, the dwindling condition of his college. The accounts of the College given in the Blue-book show that the granting of Fellowships is a growing and lucrative business. Since 1876 the College has got £4325 for its Fellowships. This is pure profit, be it remembered, and involves no outlay on examinations. In that year it received in fees from Fellows £675, but in 1880 the sum had gone up to £1100. This sum, added to the other fees, got from those who take the single, but especially the double qualification, relieves the College of all feelings of wasting, and explains the tenacity with which the system is defended. We cannot conceal, however, our regret and surprise that it should be so defended, and we cannot withdraw our conviction that a Fellowship so given and so used is a bogus Fellowship that will not bear examination, and will never command respect.

PROBABLY no one who has personally observed the working of the Contagious Diseases Acts questions their value, either from a sanitary, a social, or a moral point of view. There may have been instances of maladministration at the outset, when the Acts first came into operation; though it must be confessed we have never seen a tittle of evidence that even passing inconvenience was ever inflicted on an individual who did not lay herself or her conduct open to misconstruction by the officers charged to enforce the law. If, however, there had been cases of mistake and wrongful apprehension, that would in no way affect the question of public expediency, or qualify the fact that the garrison towns wherein these Acts are in force are no longer, as they once were, hotbeds of vice, forming poison-centres for the whole country, and demoralising the entire community. The contrast apparent between the present state of such towns as Portsmouth, for example, now as compared with thirty years ago, is as the difference between light and darkness—

between a baited trap for the youths and men who had occasion to pass through that town, or perhaps reside in it for a while, and a place where it is not only possible, but easy, to live a life of purity, because vice is no longer allowed to flaunt its false colours in the streets, and the stewards of immorality are kept out of sight, and must be wilfully sought by those who are bent on ruining soul and body alike.

We do not yield a single point to the opponents of these Acts in the score of interest for the welfare of the women themselves. A great deal of arrant nonsense is talked and written about "seduction" and the "betrayal of virtue." Practically, not a tithe of the young women alleged to be led astray are so conducted into the paths of vice. They are either directly trained to evil practices, or their youth is so mismanaged by prudish or ignorant though well-meaning relatives that they go wrong of their own innate wilfulness or depravity. Meanwhile, it is a fact which cannot be gainsaid that where the Contagious Diseases Acts are in operation the path of sin is neither so secret nor so inviting as that which lies open elsewhere. If anyone with a particle of moral instinct will take the trouble of walking through Hyde-park, say from the Marble Arch to Apsley House, down the drive to Albert-gate, and thence across by the cab route to Victoria-gate, and back to the point from which he started, between ten and eleven o'clock any dark but fairly fine night, he will not only cease to doubt the need for police supervision, or to question the wisdom of retaining these Acts where they are already in operation, but he will recognise the policy of extending the Acts to the entire country. We do not for a moment assume that all, or even a large proportion, of the young women who are to be seen misconducting themselves in the parks are actually abandoned. We venture no opinion on that point; but of this we are sure, that if the Contagious Diseases Acts were in operation in London the great majority of these women would be prevented or deterred from parading their seeming lack of decency in a way which distinctly tends to the increase of the evil it is desired to limit and repress. For the sake of the female population as well as of the male, and particularly for the multitude of young persons who are on the brink of an abandoned life, the extension of the Acts is most earnestly to be desired.

Of course no doubt has ever existed as to the value of the Contagious Diseases Acts from a health point of view. The opponents of the Acts have never, so far as we are aware, dared to question this phase of the issue. On the contrary, they adroitly contrive to wrest the fact to their advantage, by contending that we are reducing the penalties of wrong-doing, and thereby playing into the hands of transgressors of the moral law. This is the so-called "religious argument." A truce to so base and blasphemous an abuse of the sacred name of religion. As well might it be contended that by promising forgiveness to the worst of malefactors, and extending His mercy to the Magdalens of the city in His day, the Founder of the Christian religion "offered a premium to vice." This is precisely the line of reasoning adopted by the Pharisees when they marvelled whether the SAVIOUR knew what sort of woman she was who washed His feet with her tears and wiped them with

the hair of her head. The Master had no such scruples as those which cripple the charity and pervert the judgment of the opponents of the Contagious Diseases Acts. He went about doing good, even though by so doing He was classed as the friend of sinners. The supporters and promoters of these Acts, among whom we expressly declare ourselves, both on medical and moral grounds, must be content to be misrepresented. We do not wish to smooth or straighten the path of vice, but we desire to clear it of its traps and to facilitate the recovery both from disease and from vice of those who are lured or wilfully stray along that path. We are convinced that the Acts are of high social and moral value, and we would earnestly and warmly endorse the demand which is about to be made to the Legislature for their confirmation and extension.

SOME recent letters in *The Times* have drawn attention to certain obvious discrepancies between the analyses of London water presented monthly to the Registrar-General by Professor FRANKLAND, and those made on behalf of the Water Companies by Messrs. CROOKES, ODLING, and TIDY. These discrepancies are not very great. They relate mainly to the suspended matter, or, in other words, to the turbidity of the water; Professor FRANKLAND frequently recording turbidity due to imperfect filtration at times when the other chemists find the same water clear. The integrity of all the chemists concerned is above suspicion, and although some small allowance may fairly be made for bias due to previous experience or preconceived views, it is probable that the differences arise mainly from the circumstances under which the samples are collected.

A vast improvement has taken place during the last few years in the quality of the water supplied to London by the Companies who enjoy the monopoly. At one time much of it was exceedingly bad. Successive epidemics of cholera were proved to have been propagated by the contamination of the water-supply by the excreta of cholera patients. Elaborate inquiries were instituted, and the result has been that the Water Companies have been forced step by step into the adoption of better methods of collection and filtration; while the sanitary authorities of the basins of the Thames and Lea have, sometimes after protracted resistance, been compelled to divert raw sewage from the rivers which furnish the main supply of the metropolis. At the present moment the water-supply of London is fairly, though not perfectly, satisfactory. No extensive sewage pollution is permitted, and the Water Companies, stimulated by a wholesome fear of penalties, have expended large sums in storage-reservoirs and filter-beds. Probably nearly all that can be done with water drawn from rivers which form the natural drainage of thickly populated and highly cultivated districts has been done, and Londoners may well be thankful for the great improvement which has been effected.

Among those to whom this beneficial change is due, Professor FRANKLAND occupies a foremost place. Dr. JOHN SNOW first showed the activity of water in carrying the germs of zymotic disease. Mr. SIMON, Dr. FARR, Mr. NETTEN RADCLIFFE, and many others, did good work in confirming the theory and rousing public interest in the subject. But until Professor FRANKLAND took the matter in hand no satisfactory means of analysing doubtful waters

was known. His elaborate method of analysis by combustion is now used by all careful chemists. It tells us, with wonderful exactness considering the difficulties, the quantity of organic carbon and nitrogen contained in water. This, with a knowledge of the ammonia, chlorine, nitric and nitrous acids, suspended matter and total solid matter in the water, a determination of the oxygen required to oxidise the organic matter, and a careful microscopic examination, enable a very fair judgment to be formed, not only as to past history, but as to present condition. Professor FRANKLAND has done all this, and more, for the London waters for many years. His views have throughout been consistent, and they are now pretty generally accepted by chemists, as well as by the medical profession. His numerous and elaborate analyses have been tabulated with great care, and many sound generalisations founded on them. They show with great distinctness the progressive improvement to which we have referred.

At the present moment, then, we agree that there is not much fault to find with the London water-supply. If sewage can at all times be excluded and if we are sure that the filtration shall at all times be perfect, or nearly perfect, there remains only the objection that the water is, after all, to a great extent land drainage and the drainage too of land highly cultivated and thickly populated. This objection, although real enough, is not sufficient in our opinion to condemn the water, for there is no evidence that it points to any distinct mischief as a practical consequence. But we confess that we cannot as yet feel much faith in the arguments or statements of the water companies. With regard to the Thames, particularly, the watershed is so great, and pollution, in spite of prohibition, so easy, that complete confidence would, we believe, be credulity. It cannot be too often repeated that the chief danger of a water arises not from its usual but from its accidental and occasional pollution. The mere quantity of organic matter, however accurately indicated by analysis, is but a slender guide after all. The evacuations of a single cholera or typhoid patient would be a far more dangerous contamination than the healthy excreta of an hundred people. From such dangers as this persons who drink Thames water can never be wholly free. We have no wish to exaggerate the risk, but to forget its existence would be foolish and wrong. Our readers, who are so often face to face with the subtle zymotic poison, are not likely to ignore it, but it is right that it should from time to time be brought before the notice of the public.

M. DUVAUX, Minister of Instruction in France, has issued a circular addressed to the directors of lycées upon the subject of the kind and extent of the teaching best adapted to the minds of the youthful pupils under their charge. In this circular the system hitherto for the most part in vogue of cramming the memory with dates and dry facts is deprecated, whilst the professors are enjoined to devise methods which shall be calculated to draw forth the intelligence of the learners and foster their thinking powers. The "*enseignement*," which is published in *La Semaine Française*, is eminently judicious, and worthy the attention of all who are engaged in the training of youth.

THE death is announced of the celebrated chemist, Professor Wöhler, of Göttingen, at the age of eighty-two.

## Annotations.

"Ne quid nimis."

### TREATMENT OF THE WOUNDED IN EGYPT.

WE are in a position to contradict the statements which have been made regarding alleged inadequacy of the arrangements for the succour of our wounded at the storming of Tel-el-Kebir, on Sept. 13th. A medical eye-witness, not a member of the Army Medical Department, but attached, during the engagement, to the advanced field hospital, writes as follows:—"In the early morning Tel-el-Kebir had fallen, and we pitched our tents by the canal. We had been out of range of infantry fire, but were exposed to shell fire, especially when the Egyptians caught sight of the siege-train, which advanced consecutively with us and on our right, previous to our taking up a fixed position. About 10 A.M. the wounded began to pour in, and we set to work, operated and dressed until thoroughly exhausted. By 1 o'clock or earlier they were comfortably settled in the boats and horse-boxes ready in the canal, and gently towed down the canal to Kassassin, and others were sent on in the afternoon and evening. I accompanied the boats in the evening, and returned to Kassassin. There I dressed all the wounded officers with antiseptic dressings, and then went on in charge of a team of wounded to Ismailia. Since then some 400 wounded have passed through our hands at the base hospital, and the work has been enormous. However, every one has put his shoulder to the wheel, and the rapidity and comfort with which the wounded have been brought from the field to Kassassin, thence to Ismailia, and finally to the *Carthage, Courland, and Orontes*, have been beyond expectation. As for the base hospital, I must say that the arrangements, ventilation, and surgical work, would do credit to any London hospital." This statement is substantially confirmed by our special correspondent in Egypt, who telegraphed from Alexandria on Wednesday last that "the medical service was working admirably in spite of almost insurmountable difficulties." It must not be forgotten that in this expedition everything was subordinated to the military exigencies of the campaign; it was imperative that the troops at Ismailia should be pushed to the front with the least possible delay; transport being almost nil, the advancing column outmarched all supplies; the sick therefore of necessity suffered with the rest; but the field hospitals were sent forward with all speed, and medical aid for the wounded was available almost as soon as the casualties occurred. The exertions and risks of the Medical Department have been equal to those put forth and encountered by other branches of the Service. We cannot but deprecate hasty and unfounded aspersions being cast on the medical service because the horrors of war entail of necessity some suffering and privation on the sick which are not experienced in times of peace. This fact is, we fear, too often forgotten when the excitement of battle is over.

### SANITARY INSTITUTE OF GREAT BRITAIN.

IN his presidential address to the Sanitary Institute of Great Britain, at Newcastle-upon-Tyne, Captain Douglas Galton impressed upon his audience the necessity for securing cleanliness in all the conditions affecting communities, if a high state of public health was to be attained. Many years ago Mr. Simon laid down the rule that uncleanness is the chief cause of removable disease, and Captain Galton in an interesting review shows how fully recent researches have confirmed that view. Organisms capable of producing disease find the conditions favourable to their development in ill-drained and ill-scavenged towns, in water services and water receptacles exposed to filth, in over-

crowded courts, yards, and dwellings, and in water-logged and marshy soils. Hand-in-hand with the removal of conditions bringing about want of cleanliness of air, soil, or water, there has been a well-marked improvement in health and in preventable mortality, and many striking examples of this were brought under the notice of the Congress. The removal of infection from amongst a people is closely allied to the removal of the filth by which that infection was produced or spread, and hence the experience obtained as to compulsory notification of infectious diseases, and the isolation of the sick by sanitary authorities, found an apt place in the address. Many of the details entered into as to the results of the provision of proper means of sewerage in towns heretofore unhealthy, of securing the utmost possible cleanliness in the air breathed by mechanics and others, and of measures conducing to cleanliness of person and of house, are of considerable interest, although some of the inferences must be regarded as a little strained. Thus where the influence of smoky air on health is illustrated, comparison is drawn between the death-rate in twenty-three large manufacturing towns and that in the rural districts of Wilts, Dorset, and Devon; whereas it must be obvious that many other influences, and some of these of far more importance than the condition of the atmosphere as regards smoke, must have contributed to the results quoted. There is also one portion of Captain Galton's address which, in our opinion, exhibits a departure from the general principles he elsewhere lays down; and that relates to his remarks as to water-supply and the pollution of rivers. Captain Galton would evidently advocate wholesome water, and he deplors the delay in the enforcement of the provisions of the Rivers Pollution Act, but in almost the same breath he says that where a country is sparsely populated the question of the pollution of streams is comparatively unimportant, because a primary dilution with sewage will probably be rendered innocuous after a "run of a certain number of miles," the actual distance being admittedly indefinite; and he then goes on to express the opinion, with regard to waters so contaminated, that "there has never been a well-proved case of an outbreak of disease resulting from the use of drinking water, where the chemist would not unhesitatingly on analysis have condemned the water as an impure source." That this statement is not based on trustworthy evidence we have shown elsewhere in an annotation as to the Bangor water-supply; and we must further add that the implied consent which is here given to the fouling of water-sources and of rivers which may be resorted to for drinking purposes, in the anticipation that no harm will come of it, is in direct opposition to the contention which elsewhere pervades the address, and which is to the effect that all preventable causes of sickness and death should be done away with in the interests of public health.

### BANGOR FEVER AND THE WATER-SERVICE.

THERE is every reason to believe that the Bangor epidemic has acquired a firm hold on that town and its immediate vicinity. The fear which we expressed in an early stage of the outbreak to the effect that though the immediate cause of the disease had probably been arrested by the action taken at the intake of the water-service, a further spread might be anticipated owing to the houses being in unbroken communication with an ill-ventilated system of public sewers, has become true to an extent which ought to act as a warning to other towns with similar drainage defects, the disease having already attacked over 500 persons. It is much to be deplored that the Local Board of Health set their own opinion against that of their medical officer of health, and declined to accept his view that water pollution was the real cause of the outbreak. Had they at the first onset acted on the advice of their proper adviser in such matters

much sickness and distress might have been avoided. Their action, however, towards Dr. Rees was singularly unfortunate, and it placed him at the moment in a position of great difficulty. Even before the opinion he had expressed as to the cause of the disease was confirmed by Dr. Barry, Dr. Rees strongly maintained the position he had taken up, and this notwithstanding much opposition from those who were ignorant of the subject they were attempting to deal with, and we fully concur in the resolution of sympathy which was unanimously accorded him by the North Wales Branch of the British Medical Association at their recent meeting in Rhyl. We cannot but regret that an effort is still being made to evade the real question as to the infective property possessed by the water-supply at the commencement of the epidemic, and that one branch of science is by some persons being pitted against another for this purpose. We have no wish to undervalue the services of the chemist in connexion with public health inquiries, but it cannot be too widely understood that the results of a chemical analysis of a few samples of water taken from such a source as that at Bangor at a given date or dates can have but little bearing on the question as to whether any portion of the water delivered to the town had or had not on certain occasions, and these different from those at which the samples were taken, received some property for harm from an infected source. Indeed, chemists of high standing fully admit themselves as incapable of detecting such a poison as that of enteric fever, even when it is known to be in a given sample of water; and Dr. Frankland has stated that he has himself mixed the evacuations of a patient dying of cholera with a good water, and having submitted the sample to analysis he has "been unable to detect anything unusual in the water." "Chemical analysis," he goes on to say, "is unable to detect these small quantities of morbid matter which are calculated to transmit disease to people drinking the water." We would urge the Bangor sanitarians to get rid of all possible sources of pollution to what may be made an excellent water-service, and then they need not trouble themselves as to whether foul matters gaining access to the supply can or cannot be detected by one or another method of scientific research.

### METROPOLITAN BAKEHOUSES.

A GOOD deal of attention has recently been given to the condition of bakehouses in the metropolis. Until the year 1878 all London bakehouses had been under the control of the vestries, and, working under the provisions of the Bakehouse Regulation Act, the officers of the sanitary authorities had effected considerable improvements in these places. That all bakehouses were in a satisfactory condition no one could pretend to say; they were to a large extent in the occupation of Germans, who were not noted for habits of personal cleanliness, and the powers conferred by the Bakehouse Regulation Act were not sufficient to enforce as perfect a sanitary condition as those who eat bread would wish to find in the places where the bread is made. But in 1878, instead of strengthening the limited powers which the Act conferred upon the vestries, the whole Act was repealed, and its clauses transferred to the Factory and Workshops Act of that year. By this change the duty of inspecting bakehouses was made to devolve upon the factory inspector, but by the repeal at the same time of certain words in the Nuisance Removal Act, a bakehouse under certain circumstances became a nuisance with which the sanitary authorities could deal, but their right to visit every bakehouse because it was a bakehouse was lost. Their duty, however, does not appear to have been clearly understood; in some districts the vestry inspectors visited as before, while in others it was thought that these officers had no more control over bakehouses than over

dwelling houses. This point was decided in the early part of the present year, when the bakers in Clerkenwell refused to admit into their bakehouses the inspectors of the vestry of that district. Appeal was then made to the Home Secretary, with the result that an opinion was given that the bakers were right in their interpretation of the law, and that the officers of the sanitary authority had no right of entrance unless a nuisance existed on the premises. The subject was then brought before the Society of Medical Officers of Health by Mr. Shirley Murphy, who pointed out that in his own district in St. Pancras only about one-third of the bakehouses had been visited by the factory inspector since the passing of the Factory and Workshops Act in 1878, and that there was urgent necessity for the registration of bakehouses, and their control by the vestries under proper regulations. On that occasion several other members of the Society stated that the bakehouses in their districts had not received more attention than those of St. Pancras, and on Dr. Bristowe's suggestion it was decided to make a definite inquiry on this point. Shortly after this meeting a report by Mr. Lakeman, an inspector under the Factory and Workshops Act, brought before the public a number of unsavoury details concerning the condition of these places, and he expressed the belief that his visits would remedy the evils complained of. How this is to come about we do not know. The reports of Dr. Bristowe, Dr. Tidy, Mr. Liddle, and Mr. Murphy show clearly enough that the visits of Mr. Lakeman and his colleagues are not sufficiently numerous to have any control worth the name over the three or four thousand bakehouses situated in the metropolis; indeed, the change of authority is apparently responsible, at any rate in some degree, for the very nastinesses of which Mr. Lakeman complains. The relation existing between the condition of the bakehouse and the health of the public is sufficiently close to warrant the sanitary authorities in claiming some power of control over the former. It is indeed a matter of surprise how this control ever came to be lost. Our metropolitan sanitary authorities are not perfect bodies, but there is sufficient evidence that inspectors under the Factory and Workshops Act are unable to deal with this subject in a satisfactory manner. The best course will be, therefore, for bakehouses again to come under the control of the vestries, who should have increased powers to deal with them.

#### THE GERMAN APOTHECARIES' CONGRESS.

THE Union of German Apothecaries numbers 2755 members, who are distributed throughout all parts of the empire, and who have in most cases, for local purposes, their own separate organisations affiliated to the central body. This Union has held at Berlin during the present month its eleventh annual congress. Amongst the matters of interest brought forward was the action which has been taken by the Mecklenburg Apothecaries' Union in conjunction with the Mecklenburg Medical Society for the purpose of restraining the sale of advertised specifics. Reference was made to the new edition of the Pharmacopœia Germanica, which contains many changes as compared with older editions; a work is in preparation which will give a summary of these changes. Professor Reichardt, of Jena, furnished some interesting details as to volumetric analysis according to Gay Lussac's system, with special reference to the testing of preparations connected with pharmaceutical chemistry. He remarked that volumetric analysis combines the use of measures with chemical analysis, and has certain advantages over analysis by weight, from the fact that it does not depend upon the exactness of the scale and the skill of the analyser, but upon the visibility of a reaction much more easily observable than is the case with other methods. The funds of the Union amount to about £13,000. There are

thirty stipends of £7 10s. per annum granted from the pension fund, and an extension of the pension list from another branch of the revenue of the Union is in contemplation. Out of the general fund for the maintenance of the families of deceased apothecaries the estimated annual grants for 1883 are 100 in number, amounting in the aggregate to £800. The question of the employment of persons without any pharmaceutical training as salesmen in chemists' establishments was discussed, with reference to the regulations introduced this year by the Government of Saxony. It was agreed that such a step was both unnecessary and unadvisable in the interests of the safe exercise of the apothecary's calling, and that if adopted it would lead to further evils by the fact that persons would be introduced into the calling who might afterwards be found injurious to it. Dr. Tschirch read a paper upon micro-chemical methods of reaction in the service of technical microscopy. Dr. von Waldheim, of Vienna, reported upon the progress which has been made in the preparation of a Universal Pharmacopœia. An international commission of thirty-two delegates (from Europe and America) has been engaged in the task. Its object is the publication of the formulæ of those simple and compound medicinal substances respecting which, on account of the potent nature of their component parts, it is in the interest of the public that when prescribed by a physician of any country they should be dispensed of the same quality and strength by any apothecary in the civilised world. The questions of deodorisation and disinfection were discussed by Dr. Franke of Charlottenburg in an exhaustive paper, which completed the programme. Wiesbaden was chosen for the next annual congress.

#### THE EMPLOYMENT OF TOBACCO.

IT is probable that no physiologist would contend that tobacco in any form is essential to the well-being of the body. Thousands of healthy men and the vast majority of women never touch it; yet it is certain that its use is becoming daily more frequent, and that when once introduced into a country it is almost hopeless to eradicate the taste for it. It is clearly not necessary for the exercise of the highest intellectual powers. Dante and Chaucer, Michael Angelo and Raphael achieved their triumphs without its aid; and no encomium of its virtues will be found in the wise sayings of Sancho Panza or in the pages of Shakspeare; nor have we any record that Milton composed under its influence, unless, indeed, a habit of smoking in bed led to his not very clearly explained connubial disturbances, and to his tart treatise on divorce. Be this as it may, the eagerness with which it is sought after by its devotees, who allow neither manners, nor the presence of ladies, nor the comfort of others to interfere with their enjoyment, the distress that is occasioned by a temporary failure of the pernicious weed; the difficulty with which the habit of smoking once acquired is broken—indicate clearly enough that it supplies some want in the economy or exercises some influence on the system which cannot be replaced by other means. To many men a poison, to others tobacco is the very staff of life, and to be without it is the extremity of misery. Enforced abstinence from it is to many a convict the severest part of his sentence, and the cunning and deception, as well as bribery, employed to effect its introduction into prisons are well known. An amusing address has lately been delivered by M. Bouley to the Société contre l'Abus de Tabac, on the economical and hygienic aspects of the use of this narcotic. The total value of the tobacco smoked in France amounts, he tells us, to no less than 352,538,000 francs, nearly eighteen millions sterling, which immense sum represents the increase in the taste for tobacco since the year 1830, when this singular habit took its origin from the leisure of the Corps de Garde after the

restoration of the National Guard suppressed by Charles X., M. Bouley points out how smoking has effected an intellectual separation between men and women, conversation being no longer maintained after dinner as in his earlier years. The men are anxious to smoke, and the ladies retire early, to the great detriment, in his opinion, of the mental faculties of both sexes. He is reminded by the present condition of things of Voltaire, who, when condoled with by Piron on the ill-success of one of his comedies, ventured to say, "Well, at any rate, they didn't hiss it." "No," replied Piron, "How could they, when they were yawning all the time?" In France the State promotes smoking, since each soldier receives, every ten days, 100 grammes of tabac de cantine, on payment of the extremely moderate sum of fifteen centimes. It is given in the belief that it constitutes to some extent a substitute for food and affords relief to, or at least prevents grumbling at, the monotonous character of the diet. As long ago as 1854, Marshal St. Arnaud, when at Varna, wrote to the Intendant of the War Department: "Have you sent tobacco for the troops? It is very important, for tobacco is undoubtedly the best means we possess to prevent attacks of nostalgia and to alleviate the miseries of the bivouac." General Brack, again, in his "*Traité des avant Postes*," strongly insists that a taste for smoking should be cultivated in the light cavalry, on the ground that it keeps him awake, employs spare moments that would otherwise be employed in thinking, and keeps him near his horse, which he sees has its forage and is not abused. "How comforting it is," he adds, "in the early morning; it drives away sleep and renders the rain less cold, thirst less severe." The pipe, again, demands a steel and some tinder, and the implements for the production of the bivouac fire are therefore always at hand. But there is another side to all this. Dr. Blanchet, an army surgeon, writes that "constant association with the soldier, and inquiring into the effects of smoking, has taught him that the illness of many men is to be traced to the abuse of tobacco alone. Ulcers on the lips, in the mouth, on the tongue, in the nose, necrosis of the maxillary bones, are not uncommon results of its use. Others suffer frightfully from gastralgia, gastritis, and enteritis; others from vertigo, mental debility, and even transient attacks of mania." Who is in error here, the general or the surgeon? What have our English surgeons to say to it? In moderation, as Sir B. Brodie said long ago, it probably acts as a calmate to the nervous system, especially when in a condition of excitement and worry, and its abuse only should be deprecated.

### THE POVERTY THAT HIDES.

THE poor are always with us, and yet we know them not. The poverty that parades its needs and is perpetually asking for "relief" is not the real indigence that true humanity should be most solicitous to help. It is the poverty that hides which the genuine philanthropist should search out and succour. In this great city there are thousands who know the bitterness of unsatisfied hunger, who endure the misery of that most blighting of all cold, the chill of starvation; who suffer torments of mind-worry and wretchedness; and who are, in short, dying of destitution while they keep up an external appearance of respectability and even of content. Medical men who are admitted to see life stripped of its tinsel, especially those who have to deal with the mental phases of human nature at close quarters and in its weakest moments, when pretence is no longer possible, have this hidden poverty brought painfully home to them. The outside public has no conception of the extent and depth of the impecuniosity that prevails, and the bitter aching void that is unsatisfied. We pity the so-called "starving poor": Heaven help the starving "well-to-do" and even seemingly "wealthy"! It is a grim fact that there are at this moment

members of the professions, tradesmen, clergymen, and educated persons of all classes and grades of society, who are poorer and more at a loss how to feed themselves and their families than the average "poor" upon whose recognised needs society is wont to exhaust its charity. Would that there could be a "secret service fund" managed by a committee of trusted philanthropists who would not need to publish their doings to the world, and who had the wisdom to conduct their mission of mercy with the tact that genuine benevolence always demands. The sufferers of whom we are speaking, and for whom we would plead, not only affect, but feel, that pride in life that absolutely deters them from making their circumstances known. They would, and do, die rather than confess the urgency of their poverty. When we read of cases of "starvation" that attract notice by the finding of coroners' juries, and disclosures made before the magistrates, we wonder how many in this ostentatiously charitable community of ours even suspect the existence of the poverty that hides.

### THE INFLUENCE OF SMALL-POX HOSPITALS.

IN connexion with this subject, which we commented on last week, we learn that some important experience has been acquired at Rochdale. Small-pox became epidemic in the borough during the latter half of 1881, and by the first week in December as many as 440 cases had occurred in 310 houses. At that date a disused workhouse was taken over by the corporation as a small-pox hospital; 163 patients were admitted at intervals, and soon after this a series of complaints were addressed to the Local Government Board by persons residing in the vicinity of the hospital, to the effect that a marked spread of the disease had been brought about in the immediate neighbourhood of the hospital buildings. Dr. Thorne Thorne was instructed to make inquiry into these allegations, and his report has been forwarded to the corporation. The inquiry instituted consisted partly in a detailed investigation of the circumstances of the outbreak, and partly in a public inquiry with a view of eliciting all available information on the subject. The report traces the course of the epidemic during the twenty weeks ending April 29th, 1882, and during which any injurious hospital influence might have been in operation; and it compares the incidence of the epidemic on the various parts of the borough during this period with that which obtained during the prevalence in the twenty-six weeks before the use of the hospital. In order to secure accuracy in this comparison, the corporation, at Dr. Thorne's suggestion, paid a fee to all medical practitioners in and around the borough with a view of securing a return of all cases of small-pox which had occurred. As the result, it appears that 310 houses, out of a total of 17,000 in the whole borough, were attacked before the hospital was established, and 334 after it came into use. The rate of attack per 100 houses was, however, remarkably different, in point of locality, during the two periods in question. Before the hospital was provided it was 1.82 for the entire borough, and 0.36 in 827 houses lying within a quarter of a mile of the then empty hospital buildings; but after the hospital came into use the percentage of houses attacked within the quarter-mile area rose to 5.66 as opposed to 1.96 for the whole borough. In other words, to quote Dr. Thorne's report, "Whereas the rate of incidence upon the borough as a whole remained much the same during the two periods, it was more than fifteen times greater on the houses lying within a radius of a quarter of a mile round the hospital after that building was used for the reception of cases of small-pox than it had been before." It is further shown that this rapid diffusion of the disease in the vicinity of the hospital during the period referred to was not due to any general extension of the infection in that direction, but that it occurred quite independently of any such

cause. The details of hospital administration appear to have been so exceptionally lax that it became impossible to discriminate between the several methods by which influence for harm might have been brought about; and it is implied that in the face of so many obvious sources of uncontrolled personal infection which were allowed to come into operation, no conclusion could be arrived at as to whether any, and if so how much, of the injurious influence could have been brought about by aerial conveyance. The report, however, shows distinctly that the aggregation of large numbers of small-pox patients in the neighbourhood of dwellings is, from some cause or other, attended with results which do not follow on the isolation of patients suffering from the other infectious fevers.

### THE TREATMENT OF ENLARGEMENT OF THE SPLEEN.

INJECTION of drugs into the substance of the spleen has been lately tried as a means of obtaining a reduction of the bulk of the organ in cases of hypertrophy. Hammond obtained a rapid reduction in size by the injection of ergot. Kussmanl, of Strasburg, endeavoured to lessen the size of the organ by simple puncture with a large needle, hoping thus to produce a hæmorrhagic infarct which might cause some atrophic shrinking, and by repetitions of the process a considerable reduction in size of the organ. The result, however, disappointed his expectation, for no marked effect was produced by fourteen punctures. Galvano-puncture was tried four times, with no better result. A parenchymatous injection of 1 gramme of sclerotic acid was made, and death followed in six hours. At the autopsy, no trace of hæmorrhagic infarct could be found in the organ; only around one of the punctures was there a reddish zone. The patient was suffering from leucocythæmia, and, whether death was caused by the sclerotic acid or not, the lesson is certainly taught that injections should be made into the substance of the spleen in that disease with extreme caution. Mosler, of Greifswald, has tried injections in other forms of enlargement with success, but prefers Fowler's solution to ergot, and has found those cases most suitable in which the spleen is hard. He thinks it well, also, to apply ice to the splenic region for some hours before an injection is given. A remarkably good result has been reported by a St. Louis physician, Dr. Emanuel, of the internal use of ergot. The patient was a gentleman forty-three years of age, whose spleen was so much enlarged as to fill almost the whole of the abdominal cavity. It was firm and tender, and the patient affirmed that the swelling had existed for two weeks only. There was no history of malarial disease. Thirty drops of Squibb's extract of ergot were given three times a day, and the dose gradually increased to sixty drops. In three days the spleen had lost much of its hardness, although its size remained nearly the same. A week later, however, it was distinctly smaller; every day the diminution went on, and in a few days more the spleen was reduced to nearly the normal size.

### THE PROTECTIVE POWER OF VACCINATION.

ANTI-VACCINATIONISTS have been desirous to find in the interesting quarrel which is now going on in Switzerland between the Cantons and the Federal Council evidence of the growth of an increased objection not only to compulsory vaccination, but to vaccination itself. It has, however, been clearly shown that the dispute which has arisen has really no reference to vaccination at all, but is simply an unwillingness on the part of the Cantons to allow the Federal Council to legislate on subjects which have until recently been solely under the control of individual Cantons. There is, therefore, nothing in recent events in Switzerland to lead to the belief that vaccination is less valued than formerly.

That public opinion should not be equally strong upon this or any other subject in every part of Switzerland or England is no matter for surprise, but the question of the extent to which individuals are protected against small-pox is one which does not alone concern the particular town in which they are resident, and cannot therefore in our country, where the railway gives such ample opportunity for the communication between one town and another, be wholly entrusted to local authorities. A correspondent, Dr. Mitchell, writing from Meudon in France, urges that the real issue involved in the difference of public opinion with regard to vaccination is, whether vaccination really protects, and he offers to join in an experiment by which he and an unvaccinated person shall submit to the inoculation of small-pox. In a letter to *The Times* some two years ago, Dr. Cory pointed out that this was the simplest way of proving by direct experiment the amount of protection afforded by vaccination. There are legal difficulties in the way of intentionally carrying out this proceeding in England, but the unintentional inoculation with small-pox matter of vaccinated attendants in small-pox hospitals is a matter of daily occurrence; and although an occasional local abscess is produced, the fact that these people escape small-pox is well known. It can hardly be expected that people who are unwilling to accept this evidence, which is constantly before their eyes, will be convinced by other experiment, however definite in character it may be.

### CHLOROFORM CATASTROPHES.

TWO fatal accidents in the administration of chloroform have recently been added to the list of the lamentable records of chloroform catastrophes. They were very different in character, and one of them ought not, in fairness, to be attributed entirely to the anaesthesia. This was the case of James Butterworth, who (as the inquest held on him on September 2nd showed) was admitted into St. Bartholomew's Hospital with fracture of the jaw. Death occurred during the administration of the chloroform, but at the post-mortem it was found that the larynx had been injured, and that there was extravasation at the base of the tongue, and accumulation of blood in the trachea. In the second case the death occurred at the London Hospital on September 4th, also during administration. In this instance cancer of the tongue was the disease for which the operation was intended. The death in the first of these cases was evidently largely due to asphyxia, and we should be inclined to excuse chloroform as the destroying agent, while we should admit that for the particular operation it was a better agent than ether. In the second case the phenomena were those purely of chloroform death during the stage of excitement and muscular contraction. There were the usual sudden arrest of the heart, lividity of the face, cardiac apnoea, and collapse.

### THE NOTIFICATION OF DISEASE.

THE following resolution has been passed at the meeting of the Social Science Association by a majority of forty-one to sixteen:—"That this department considers it highly desirable in the public interest that the Legislature should at the earliest opportunity pass a general enactment for the compulsory notification of infectious diseases, on the principle of the Bill introduced into the House of Commons in the past year by Mr. Hastings." The subject was introduced by Mr. W. H. Michael, Q.C., who condemned the opposition of certain members of the medical profession to the proposed immediate notification of disease. Dr. Littlejohn, of Edinburgh, strongly supported the system practised in Edinburgh, of which he said there were no complaints. The law there requires that every medical practitioner practising within the burgh shall, within twenty-four hours

of the same coming to his notice, report to the medical officer of health every case of cholera, typhus, typhoid, diphtheria, small-pox, scarlet fever, and measles. The duty is thrown on the medical man alone. This view was opposed by Dr. Brookhouse of Nottingham, Dr. E. Whittle of Liverpool, Dr. Jacob of Dublin, and others. Dr. Cameron, Medical Officer of Health for Dublin, Dr. Alfred Hill of Birmingham, Dr. Ransome of Nottingham, Dr. Hatherley, and others supported notification with qualification. We adhere to our opinion that the duty of intimating should devolve on the parent or householder. But we must enter our protest against the piecemeal way in which this principle is being put into legislative force by furtive insertion in local Bills. If the notification of disease is to be of any use, it must be made universal and compulsory, and if the State or any local authority insists on restriction of business and isolation of cases, it must be prepared to compensate.

### ISOLATION AND PAUPERISM IN THE METROPOLIS.

NOTHING can be more unfortunate than the intimate connexion which, in the metropolis, exists between the isolation arrangements for infectious diseases and pauperism. The other day a man who lived in the Southwark-bridge-road, and who occupied a single room with his wife and two children, applied to the magistrate for help in the removal to hospital of his wife, who was suffering from small-pox. He was referred to the relieving officer, and after a day's delay he returned to explain that, as he was not a pauper, the officer in question would have nothing to do with him. Next came the statement of the vestry sanitary inspector, who said he could remove no one unless four guineas were forthcoming, and the vestry, he alleged, had no funds to meet such cases. Anything more disgraceful can hardly be conceived, and the magistrate was well within the limits of propriety in calling the whole affair "monstrous." The vestry is the sanitary authority for the district; one of its principal duties is to care for the public health within the limits of its jurisdiction; the inhabitants of the district are rated for this very purpose; and yet here we have an officer of that sanitary authority disclaiming all responsibility when a patient is lying ill of small-pox in what is described as a "densely populated neighbourhood," and needs removal to hospital in order to save the spread of infection to other members of the community. Well may London demand some alteration in the arrangements for its local government in matters concerning public health.

### THE SOCIAL SCIENCE CONGRESS.

THE twenty-fifth session of the National Association for the Promotion of Social Science has come and gone. In the Health department papers of more or less interest and importance have been read, amongst which may be enumerated the following:—Infant Mortality, by Mr. T. M. Dolan; Administration of Hospitals, by Dr. Gilbert Smith; Small-pox Epidemics as affected by the states of War and Peace, by Dr. William A. Guy; Notification of Infectious Diseases, by Mr. W. H. Michael; the Superior Prophylactic Power of Animal Vaccine against Small-pox, by Dr. Drysdale; Revaccination, by Dr. Whittle. Some of these questions will afford matter for comment next week. Meanwhile, it is somewhat depressing to reflect on the multiplicity of papers on medical topics which are produced at congresses, convened here, there, and everywhere, for almost every conceivable purpose, read to audiences who are for the most part but imperfectly capable of estimating their merits, and introduced at times and under circumstances unfavourable to the proper consideration and discussion of their subject-matter.

### MICROCOCCI IN MEASLES.

WE mentioned a few weeks ago the purport of a paper lately read by Dr. Keating before the Royal College of Physicians of Philadelphia on the above subject. The full text of the paper has been published in the *Philadelphia Medical Times*, and the interest of the subject should be sufficient apology for dealing with it again. It may, however, be remarked that four years ago Drs. Braidwood and Vacher communicated to the Pathological Society of London a paper upon the same subject, in which they described highly refractile spherical bodies in the breath of measles patients, and similar bodies, together with rod-shaped, fusiform and ovoid forms, in the corium, lungs, and liver. They pointed out the resemblance of these bodies to the vaccinia-micrococcus, and referred to some earlier work by Hallier and G. Simon in the same line. At the time, if memory serves us aright, these observations of Braidwood and Vacher were not followed up, and, perhaps owing to the fact that bacterial pathology was then less in vogue, were not much accepted. Dr. Keating's research seems, however, to substantiate their facts, although he limits his microscopical investigations to the blood. These investigations were made by Dr. Furniss, who had previously carried out a similar research in diphtheria, in association with Dr. H. C. Wood. The blood was examined daily and micrococci were found in the malignant cases only, not in those of a mild type. Dr. Keating gives notes of eight cases, all but one of which were fatal. The blood was examined after death in most of the cases, and micrococci were found not only in the liquor sanguinis, but also in the substance of the white corpuscles. In some of the cases notes are recorded of observations made on the blood during life nearly every day. In the fatal cases death occurred from cardiac thrombosis and pulmonary congestion, attributed to clogging of the capillaries by the micrococci and the destruction of the corpuscles. Believing that in this fatal type of the disease the condition is one of blood-poisoning, and that the occurrence of micrococci can thereby be explained as resembling that found in erysipelas, puerperal septicæmia, and diphtheria, Dr. Keating sought for the most active germicides as a basis of treatment. In brief, alcohol in large doses (it was given in the form of whisky) was found to be most efficacious, and its employment was suggested by its known action in checking the development of micrococci in culture solutions.

### UNCERTIFIED DEATHS.

THE Wandsworth District Board of Works has recently issued a report upon the health and sanitary condition of the union and district, and of its several parishes, during 1881. The report calls attention once more to the evil of uncertified causes of death, of which 125 were registered during the year within the district; these were equal to 3·3 per cent. of the deaths registered. Assuming that this proportion is fairly representative of the mean proportion of uncertified deaths in England, attention is called to the extent of the consequent invalidation of the Registrar-General's figures, and the dangerous facility which is thus afforded for the perpetration and concealment of secret crime. This defect in our present system of registration is undoubtedly serious, and calls for a remedy; but it is scarcely correct to speak of it as an "increasing laxity in the registration of deaths," inasmuch as the proportion of uncertified deaths has continuously declined in recent years. Neither is the proposed remedy, "the employment of medical investigation in all instances in which the cause of death has not been certified by a registered medical practitioner," so simple or easy of application as the author of the report appears to imagine. There can

be no question about the desirability of providing some system for the verification of the cause of death of persons not attended during their last illness by a registered practitioner. The Wandsworth report, however, ignores the difficulties in the way of the realisation of the suggestion. There is very far from agreement at present as to who should be entrusted with the medical examination; and it is lost sight of that while in Wandsworth the proportion of uncertified deaths is but 3 per cent., the proportion exceeds 20 per cent. in some parts of Wales, where the population is sparse, and the difficulty in the way of getting medical attendance great. A large proportion of uncertified deaths in town districts consists of cases of premature birth in which the only attendant is a midwife. These difficulties must, however, ere long be fairly faced, although the provision of a satisfactory remedy will scarcely be helped by simply ignoring the obvious difficulties which stand in the way.

#### DEATH OF SURGEON-MAJOR F. R. HOGG.

WE much regret to announce the death on the 21st instant at Morar, Gwallor, East Indies, of Surgeon-Major Francis R. Hogg, of the Army Medical Department. Dr. Hogg entered the service in August, 1858, and became surgeon-major in 1873. He served for many years in the Royal Artillery, and had charge of the Female Hospital at Woolwich for nearly eleven years; his duties there brought him intimately in connexion with the soldiers' families of the garrison, by whom he was universally beloved and respected for his untiring care and kindness in sickness or in trouble. It was owing to his indefatigable exertions at Woolwich that he was permitted, as a special case, to hold the appointment for so long; and his premature death will be regretted by numerous officers, men, and women of the Artillery, as well as by his own brother officers, by whom he was greatly esteemed. Dr. Hogg had only recently returned to India, and succumbed to disease of the heart and kidneys at the early age of forty-six.

#### LOCAL OUTBREAKS OF SMALL-POX IN PROVINCIAL TOWNS.

SINCE the remarkable and generally fatal epidemic of small-pox in 1871-2, nearly all the large provincial English towns have been exceptionally free from small-pox mortality. Notwithstanding the division of opinion with regard to the influence of small-pox hospitals upon the prevalence and fatality of the disease in London, there can be little doubt that the existence of hospital accommodation for the isolation and treatment of infectious diseases in most of our large English towns affords the most rational explanation of their recent freedom from epidemic small-pox. Dr. Goldie, the medical officer of health for the borough of Leeds, in his last monthly report gives some interesting particulars respecting a distinct outbreak of small-pox in that town during last month. This outbreak, which necessitated the prompt removal to the Borough Hospital of thirteen cases within a few days, occurred within a limited area; the drainage within this area is said to be defective, the streets are for the most part unpaved, while offensive accumulations result in and around the street gullies. The first case, and the one that appears to have been the source of infection, was that of an artisan, who was treated at home, without any special care being taken either to isolate or disinfect the clothing; Dr. Goldie states, moreover, that this small-pox patient is reported to have entertained his friends in his house, and thus to have been the direct means of infecting thirteen persons afterwards removed to hospital. When the medical officer first visited this case he found the mother engaged in washing the infected clothing, and, without any attempt at disinfection, hanging the clothes across the street. If, as is now probable,

Leeds once more escapes a small-pox epidemic, notwithstanding this sharp outbreak, it is only reasonable to attribute such a result to the recent establishment of a Borough Hospital for Infectious Diseases.

#### A POISON FOR TUBERCULAR BACTERIA.

A PAPER was recently communicated to the Paris Académie des Sciences, by M. de Korab, on the action of helenine on the bacteria of tuberculosis. The facts mentioned deserve notice, although we fear that the hopes suggested are too bright to be realised. The bacilli were cultivated in bovine blood serum, which was daily heated for a week to effectually sterilise it, and was then coagulated by a temperature of 65° C. A guinea-pig having been rendered tubercular by inoculation and inhalation, small tubercular masses were taken from it, introduced into ten tubes containing the tubercular serum, and the tubes plugged after some helenine had been poured into three of the tubes. All were kept at a temperature of 37° C. for a week, and at the end of that time inoculation experiments showed that the organism in the tubes to which the helenine had been added no longer caused tuberculosis, which was readily produced by the contents of the other tubes.

#### THE DISCHARGE DEPOT, NETLEY.

THE discharge depot for time-expired soldiers arriving from foreign stations, which has been for many years located in the Royal Victoria Hospital, Netley, has been transferred to Fort Brockhurst, Gosport; the staff detailed for it consists of a commandant, paymaster, paymaster-sergeant's clerk, sergeant-major, and three clerks and writers. The removal of this depot will be a great boon to the hospital, as during the trooping season the arrival of large parties of time-expired men not only took up accommodation required for the patients and men of the Army Hospital Corps, but their presence at times gave rise to confusion and irregularity.

MR. STEER, assistant medical officer and dispenser to the St. Olave's Union Infirmary, has been attacked with typhoid fever, contracted from a patient he was attending in the institution. Are the salaries of workhouse medical officers estimated in view of the risk of contagion involved in their duties? We throw not.

THE Swiney Lectureship on Geology, just vacated by Professor Alleyne Nicholson, whose term of office had expired, has been bestowed by the trustees of the British Museum on Dr. Ramsey Heatley Traquair, F.R.S.E. The office is tenable for five years, and is of the annual value of £144.

SMALL-POX ravages at Cape Town are reported by telegraph to be worse than ever. There have been 2000 cases, of which 600 have been fatal, mostly among natives, but the disease is spreading among the whites. It is stated to have also broken out among the military.

FOR the vacant post of Surgeon to the Fire Brigade (Southern Division) there would seem to be a keen competition. The names of twelve candidates are announced, that of Mr. Neale, late medical officer of the *Eira* expedition, being amongst them.

INTELLIGENCE has been received of the death of Georges Leclanché, at the early age of forty-three. The deceased chemist was the inventor of the battery to which his name is attached, and which is extensively employed both by physicians and electricians.

WE regret to announce the death, at his residence, Cavendish-place, of Mr. J. T. Clover, Lecturer on Anæsthetics at University College Hospital. We hope to give an obituary notice of the deceased gentleman in our next number.

THE Secretary of State for War has appointed William Beale Wallis, Esq., L.R.C.S.I., Brigade Surgeon, to be Visiting Surgeon at Colchester under the Contagious Diseases Acts, 1866 to 1869, vice W. W. Weld, Esq., resigned, from the 25th instant inclusively.

THE *Sanitary Engineer* (New York) of Sept. 14th reproduces the plans and description of the temporary hospital structures suggested by the New York State Board of Health, to be used for the care and isolation of patients suffering from small-pox and other infectious diseases.

THE spread of small-pox in the Black Country has determined the Town Council of Wolverhampton to take steps to provide accommodation for the immediate isolation of any cases that may come to their notice.

MR. LUND has, on account of failing health, resigned his post as surgeon to the Manchester Royal Infirmary, and has been appointed consulting surgeon to the institution.

JAMES THOMPSON, M.D., has been elected Honorary Treasurer of the Irish Graduates' Association.

SCARLET fever is very prevalent at Accrington, and is greatly interfering with the regularity of school work.

## Pharmacology and Therapeutics.

### PHOSPHORUS.

MEYER has been experimenting on the action of phosphorus on frogs and rabbits, employing an emulsion with gum, or a solution in 100 parts of olive oil, the alkaline reaction being carefully neutralised with carbonate of soda. A milligramme of phosphorus introduced beneath the skin caused in half an hour a transient increase in the liveliness of the animal's movements. Ten milligrammes caused at first excitement, but the animal died in the course of one or two days. No very striking poisonous effects were observed, however, even from the use of larger doses; a diminution of motor power and sensibility came on only after a considerable interval. Once set in, however, the symptoms rapidly increased, and death usually resulted in an hour. No tetanic cramps were observed, and the muscles and nerves after death preserved their normal irritability. The liver, as a rule, presented normal characters, and the heart was distended with blood, slight pulsation continuing in the auricles. Atropine had no influence upon it, but chemical excitants of muscle, salicylate of physostigmin, or camphor, aroused the heart to renewed activity. Further experiments led to the conclusion that phosphorus caused a paralysis of the automatic nerve-centres, and later affects the muscular tissue itself. In rabbits, also, no clonic muscular contractions were observed in phosphorus poisoning, but a slow steady diminution of the blood-pressure, which sank to zero in consequence of the arrest of the action of the heart. The vaso-motor nerves were not at all affected. Cases of phosphorus poisoning in man have been observed in which, without any considerable disturbance of the general system or of the central nervous system, death occurs suddenly. Meyer is inclined to regard these as cases of paralysis of the heart, for he succeeded, by introducing phosphorus directly

into the circulation, in causing complete paralysis of the heart, before any pathological change had been produced in the heart or liver which could be discovered after death. To exclude the possibility of embolism in these cases, special precautions were taken. An analysis of the blood of rabbits which had been poisoned by phosphorus showed that the amount of carbonic acid which could be extracted had diminished from 50 to 80 per cent., and he thus corroborates the diminution in the process of oxidation in the body and the increased destruction of albuminous bodies.

### CARBOLIC ACID IN TYPHOID FEVER.

M. Ramonet has recently published an account of the results he has obtained in Algeria by treating typhoid fever with carbolic acid, and the method of its use. Forty-one cases were thus treated, seventeen of which were severe, and two died, giving a mortality of five per cent., which must, under the circumstances, be considered remarkably low. The treatment consisted in injections of one gramme of crystallised carbolic acid in 150 grammes of water at the temperature of the room. One injection was given daily in mild cases, two in cases of greater severity, three in severe cases. A few drops of laudanum were sometimes added to help the retention of the enema. The time preferred for the injections was 11, 4, and 9. The injections were followed by a fall in the temperature, which might amount to 2°, and by a manifest diminution in the cerebral symptoms, headache, noise in the ear, and stupor, which might last for several hours. It is suggested that the favourable result is due in part to the antizymotic action of the carbolic acid. The dose should not exceed four grammes a day. The larger doses given by Desplats, 12 or 14 grammes, are harmful by their indirect effects. A tonic and stimulant treatment should always be associated with that by carbolic acid.

### HYDROFLUORIC ACID IN DIPHTHERIA.

M. Henri Bergeron has advocated the use of hydrofluoric acid in the treatment of diphtheria as not only giving a better result than other remedies, but also as preventing the extension of the disease. A piece of fluorspar and some sulphuric acid are placed in a lead vessel, and this is then heated in a salt bath, which is kept at a temperature of 80° or 100°; an acid vapour, easily borne, is disengaged. The apparatus is then placed on a table near the patient, who breathes it with uncovered mouth. It injures glass, which must therefore be greased, to protect it, but the vapour has no appreciable noxious action on healthy individuals. The apparatus is refilled five times in the twenty-four hours. The cases treated in this manner were forty, and three only died.

### OXALATE OF SODA.

As a result of a series of experiments on the action of the oxalates, R. Koch concludes that the neutral soda salt, injected under the skin in the form of a two or three per cent. solution, causes in frogs chiefly fibrillary twitchings of the voluntary muscles, followed by general paralysis, which comes on more or less gradually according to the dose of the poison. Excised muscles immersed in the solution present the same fibrillary contractions. In a nerve-muscle preparation the irritability of the nerve is quickly lost. Hence it is assumed that the poison in the blood produces paralysis primarily by affecting the muscles and the nerves. An increase in the number of the heart's contractions was not observed, but an increase in the force of the contractions, especially of the ventricles, was constantly observed. The injection of small quantities of oxalate of potash (one or one and a half cubic centimetres of a three per cent. solution) into the jugular vein of cats and rabbits caused only transient changes in the blood-pressure curve, whether the animals were or were not under the influence of curara. Larger doses, however, caused a considerable increase in the frequency of the pulse and of the blood-pressure. Still larger doses injected into the jugular vein caused the blood-pressure to fall to zero, in consequence of the arrest of the heart's action in diastole, but the same quantity injected under the skin only produced transient symptoms. The action of oxalate of potash on frogs and cats was similar to that of the soda salt. Some experiments were also made with oxalic ether, but no effect was produced which could be ascribed to the oxalic element.

### THE SUBCUTANEOUS INJECTION OF APERIENTS.

Dr. Hiller of Berlin has experimented on the subcutaneous use of certain purgatives, chiefly aloin and substances obtained from colocynth. To produce a mild aperient effect (associated with some griping) it was necessary to use one or

two syringefuls of a solution of one part of aloin in eight of glycerine. The action of the bowels took place about six or eight hours afterwards. Thus the dose required and the time of its action were nearly the same as when given by the mouth. Merck's "pure colocynthin," a glucoside of colocynth, and "ditrullin," a resinoid of the same, had a very drastic purgative action when given internally in a dose of five to ten milligrammes. A half or whole Pravaz syringeful of a one per cent. solution in equal parts of alcohol, water, or glycerine, caused several loose stools in from four to six hours after the injection, with sharp colicky pains. The same dose was effective in half an hour when given as an injection into the bowel, dissolved in ten centimetres of water, and Hiller prefers this mode of administration when an energetic and quick purgative is required, as in uræmia. The injection into the bowel caused no pain, whereas beneath the skin it caused prolonged burning. It was found also that the official extract of colocynth was also efficient in a solution of one in thirty, injected under the skin or into the rectum. Hiller's conclusions are thus decidedly unfavourably to the subcutaneous injection of aperients.

#### THE PASSAGE OF DRUGS THROUGH THE LIVER.

Experiments have been made by Peiper on dogs provided with a biliary fistula, to ascertain whether certain drugs introduced into the alimentary canal reach the liver. In order to avoid the action of the gastric juice on the substances employed, they were injected into the bowel. If iodide of potassium were injected, a long interval (six or eight hours) was found to elapse before its presence could be discovered in the bile. Salicylic acid, given in an aqueous solution, of the strength of 1 to 300, could not be discovered in the bile, but if a more concentrated solution were employed its presence was evident at the end of half an hour. Carbolic acid seems to pass through the liver only in extremely small quantities. Both ferrocyanide of potassium and cyanide of potassium gave only negative results, although the former was found by Claude Bernard in the bile of animals after he had injected it into the veins.

#### CHLORATE OF POTASH.

On the Continent chlorate of potash is given in larger doses than in this country, and sometimes with dangerous consequences. Isambert has lately shown that if a solution of this salt be injected into the blood the heart may be arrested suddenly in diastole without any precursory symptom. Not long ago four children died in France from the effects of a chlorate of potash mixture which some sisters of charity were accustomed to distribute as a remedy for sore-throat. An investigation of the subject was made by MM. Brouardel and Lhote, who arrived at the conclusion that frequently repeated small doses may have fatal results. The symptoms of poisoning may be of four classes: bluish spots on the skin, sometimes a general cyanosis, sometimes an icteric tint; gastro-intestinal disorders, especially diarrhoea and green vomit; an increase in the quantity of urine, if the amount of chlorate taken was small, but a diminution if a large dose had been absorbed, and the diminution may go on to temporary arrest, followed by hæmaturia; lastly, there may be symptoms of nervous collapse and coma preceding death. Happily the toxic dose of the drug is not very small, for Germain Séé has given more than an ounce in the course of a single day without indications of danger.

#### BORACIC ACID.

Neumann has, in view of the extensive use of boracic acid, instituted experiments to ascertain more precisely its physiological effects. A dog of the weight of fifteen kilogrammes presented no marked symptoms from a dose of five or six grammes, but a marked fall in internal temperature was produced. Larger doses caused also vomiting and diarrhoea. A 3 per cent. solution injected into the pleural or peritoneal cavity did not cause inflammation of the serous membrane; but whenever the quantity injected exceeded certain limits, the animals died from paralysis of the motor nerves and muscles. Results of identical character were also furnished by experiments on rabbits and young pigs. Boracic acid was given to horses affected with glanders up to forty-five grammes (! a dose), and the nasal ulcerations were treated with the same substance. A transient amelioration in the condition of the animals was the result, but none recovered. Boracic acid may thus be regarded as not only an antiputrescent, but also an antipyretic, comparable to carbolic acid.

## Public Health and Poor Law.

### LOCAL GOVERNMENT DEPARTMENT.

#### REPORTS OF MEDICAL OFFICERS OF HEALTH.

*Kensington (Urban).*—It appears from a report recently issued by Dr. Dudfield, the medical officer of health, that the health of Kensington, judged by its mortality statistics, was exceptionally satisfactory during the four weeks ending August 12th. The annual death-rate, although showing a slight increase upon the still lower rate in the preceding month, did not exceed 13·6 per 1000, and was 4·9 below the mean rate for the whole metropolis during the same period. It would be interesting to know how far the death-rate during the summer holiday period in such metropolitan suburban districts as Kensington is affected by the migration of no inconsiderable proportion of its population to holiday resorts. However this may be, the low gross death-rate was not the only evidence of satisfactory health in Kensington during the four weeks under notice; the district was comparatively free from zymotic fatality, as only 34 deaths were referred to the principal diseases of this class, being 30 below the corrected average for the season. This was mainly due to the exceptionally small fatality of diarrhoea, which caused but 12 deaths, or 32 fewer than the corrected average number. Nine deaths were referred to measles, 5 to diphtheria, 4 to whooping-cough, and 2 to enteric or typhoid fever. The 2 latter cases were both of children, and with regard to the 5 deaths attributed to diphtheria, Dr. Dudfield expresses doubt whether they were really the result of this disease, as one case he unhesitatingly declares to have been scarlet fever, and adds, "it may well be, moreover, that some of the other cases were really cases of croup." It is evident that fatal diseases in Kensington, as elsewhere, are not always carefully or correctly diagnosed, and we fear that the useful and valuable influence of medical officers of health in improving the quality of medical certificates of the cause of death is almost neutralised in London by the fact that nearly all medical officers of health are engaged in private practice. Dr. Dudfield dwells in his report upon several recent cases in Kensington illustrative of how infectious diseases are spread; in two of these convictions were obtained. We are glad to see that only small fines were inflicted, as such prosecutions, infinitely useful from an educational point of view, would defeat their own purpose if the sentences were heavy enough to make martyrs of the offenders. We should like to make two suggestions to Dr. Dudfield with regard to his useful monthly report. In the first place, it is a serious drawback that the report, instead of dealing with a natural month, or rather the four or five weeks most nearly corresponding with the month, relates to an arbitrary period from the middle of one month to the middle of the next; this detracts seriously from the value of the report for comparative purposes. In the second place, the utility of the report would be increased by the insertion of a table showing the more usual statistical features of such reports, which could be kept standing from month to month during the year, with the addition of a few fresh figures for the most recent month dealt with in the report.

*St. Pancras.*—According to Mr. Shirley Murphy's annual report, the estimated population for St. Pancras in 1881 was 236,209, and the increase during the last decennial period was only at the rate of 0·66 per cent., instead of 1·1 per cent. during the previous period. This has been to a considerable extent due to the demolition of houses on an area acquired by the Midland Railway. The increase in the number of inhabited houses has not kept pace with the increase of population, and the average number of persons to each inhabited house amounts to 9·5, as opposed to 9·1 in 1871. The birth-rate for 1881 was 33·6, and the death-rate 22·0 per 1000. Small-pox became epidemic in the parish during the year; and a detailed description is given of the admirable small-pox encampment which the vestry established on a site belonging to the Burial Board at Finchley; the tents having double walls and being heated with hot-water apparatus. The tents were situated at a distance of 1700 feet from the nearest dwelling-house; and there is no reason to believe that, either by means of ambulances or otherwise, the encampment gave rise to a single case of small-

pox in Finchley. In all, 547 cases were reported to the sanitary department during the year, and 376 were removed to hospital. Of the cases admitted into the tent hospital all the deaths occurred amongst those either unvaccinated or presenting no evidence of vaccination. The report deals in detail with the various causes of mortality in the parish; it explains the action taken with regard to slaughterhouses, cowsheds, bakehouses, lodginghouses, &c.; and it urges upon the vestry the adoption of some better system for dealing with the house and street refuse than the admittedly bad arrangement now existing; also the provision of a suitable public mortuary. A detailed account of the sanitary work done during the year shows that there has been considerable activity in the health department, and that much has been done to secure an improvement in the sanitary conditions under which the inhabitants are living.

*St. Giles.*—Mr. Lovett's annual report to the Board of Works for the St. Giles District shows the population to have been 45,257 in 1881; the birth-rate being 29.4, and the death-rate as high as 24.6 per 1000. The report deals in detail with the outbreak of scarlet fever, which affected the district early this year, and which was ascertained to have been due to an infected milk-supply; it explains the incidence of the various infectious fevers in the district, and it refers to an outbreak of typhus which broke out in Marchmont-place in an area condemned under the Artisans' Dwellings Act, and which was not arrested until most of the filthy and dilapidated houses in that locality had been closed under a magistrate's order. The report of the various forms of sanitary work executed shows, amongst other things, that as many as 13,248 visits were paid to houses and premises for sanitary purposes, and that 1080 articles were dealt with in the hot-air disinfecting chamber.

*West Sussex.*—The combined sanitary district for which Dr. Kelly acts as medical officer of health in West Sussex has an estimated population of 94,770, and it is satisfactory to note that, unlike some other similar districts, it has undergone no diminution in area since it was formed in 1874. Indeed, the principle of combination has evidently met with increasing approval, for two additional rural districts have united themselves with it. The birth-rate per 1000 was only 30.2, a fact to be attributed to the absence in this district of the usual proportion of females at the child-bearing age—viz., from fifteen to forty-five years of age. The death-rate, as throughout the whole country, exhibited a diminution as compared with previous years, and it only amounted to 13.9 per 1000 living; the mean age at death was forty-two years, and the infantile mortality was only 9.3 per 100 births registered. In the Steyning rural district an outbreak of enteric fever occurred at Castletown. After a first attack several sharp outbreaks took place in the neighbouring cottages, the inhabitants of which resorted to the same well. Carbolic acid being poured down the closets soon made its appearance in the water from the well, and although the water was derived from a stratum below that into which the soakage of filth took place, yet it is evident that infective matter must have trickled into it at intervals, thus causing several separate outbreaks. In the Midhurst rural district an outbreak of the same disease followed on the return home of a young woman who had been under treatment for enteric fever for eight weeks, and who was convalescent. The spread, however, did not take place until the lapse of some eight weeks after her return, and it is suggested by Dr. Kelly that the excreta, notwithstanding convalescence, remained infective, and so infected the common privy used by those subsequently attacked. He also considers that the delay in the outbreak was due to the severe cold which followed on the girl's return; the infectious quality of the excreta being first arrested by frost, and then revived on the recurrence of mild damp weather after a thaw. In the East Preston rural district a considerable outbreak of diphtheria occurred. It commenced by ill-marked cases of sore-throat and so-called "croup" amongst children attending a certain school, and it spread amongst them by personal infection until twenty-one had been attacked and six had died. The closing of the school, followed by a process of disinfection and cleansing, led to a complete cessation of the outbreak. Throughout the combined district sanitary work is steadily in progress, and though conditions, such as the pollution of the river Arun by sewage from the Horsham sewage farm, still remain to be dealt with, yet much good work has been effected. Water-supplies are improved, slaughterhouses and bakehouses are regularly inspected

and kept in a wholesome state, excrement disposal is better carried out, and a continuous supervision over the entire area is steadily maintained. The report is very complete in its meteorological, statistical, and other tables, and in the information as to local conditions which it supplies.

*Featherstone (Urban).*—The report of the medical officer of health for this small Yorkshire urban sanitary district affords favourable evidence of its sanitary condition during 1881. This district, which has not been created much more than five years, had a population at the last census slightly below 6000 persons. It is evident from its vital statistics that the age constitution of its population is abnormal. It appears from the Preliminary Census Report that the population of its area increased from 2265 in 1871 to 5901 in 1881, and during the five years of its existence (1877-81) the birth-rate averaged 48.3, whereas the death-rate did not exceed 20.1. Rapid aggregation of population has probably led to the immigration of a large number of young adults, with the natural result of a high birth-rate and of a low death-rate. The death-rate in 1881 was as low as 16.4, and considerably lower than in any of the four previous years. The zymotic death-rate (almost entirely due to an outbreak of scarlet fever) was 2.0 per 1000, against an average of 4.1 in the preceding four years. No death during the year was recorded from "either small-pox, measles, diphtheria, croup, or any of the continued fevers." With reference to the immunity from typhoid fatality during last year the medical officer of health (Mr. Buncle) calls attention to the fact that the sanitary district was formed "mainly on account of the excessive mortality in the district from typhoid fever and other diseases produced by filth and bad drainage." Notwithstanding the marked improvement in the health of the district, and the exceptionally favourable mortality statistics of 1881, the medical officer in the report before us points out many reforms which still call for the attention of the sanitary authority, and neglect of which might at any time seriously interfere with the steady improvement in the health of the district. The water-supply and the scavenging of the district still, it is said, need improvement, and the success of previous local sanitary efforts should, and probably will, secure further progress. We congratulate Mr. Buncle both on the matter and manner of his report. The few statistics given are sufficient for the purpose, and clearly arranged; they, moreover, include a concise summary of the results for past years, which, although indispensable for comparative purposes, is too frequently omitted from such reports.

*Cork.*—During the four weeks ending August 12th, the births registered came to 164, or at a rate of 27.02; and the deaths to 108. The annual deaths per 1000 gave a total ratio of mortality of 17.05; but deducting the deaths (8) which occurred in the workhouse, and therefore outside the district, the urban death-rate would then stand at 16.02. These statistics, when compared with those for a corresponding period last year, show that the death-rate of the city remains much the same; but febrile diseases, more particularly typhus fever, have since then greatly diminished.

## VITAL STATISTICS.

### HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns, 5696 births and 3374 deaths were registered during the week ending the 23rd inst. The annual death-rate in these towns, which had been equal to 19.9 and 20.0 per 1000 in the two preceding weeks, further rose to 20.8 last week. The lowest rates in these towns were 11.4 in Brighton, 12.7 in Bolton, 14.7 in Norwich, and 14.9 in Bristol. The rates in the other towns ranged upwards to 25.5 in Newcastle-upon-Tyne, 26.2 in Preston, 27.5 in Nottingham, and 28.5 in Sunderland. The deaths referred to the principal zymotic diseases in the twenty-eight towns were 559, showing a further considerable decline from recent weekly numbers; 270 resulted from diarrhoea, 100 from scarlet fever, 64 from whooping-cough, 50 from "fever" (principally enteric), 44 from measles, 24 from diphtheria, and 7 from small-pox. The lowest death-rates from these diseases were returned in Norwich and Brighton, while the highest occurred in Preston and Sunderland. The death-rate from diarrhoea showed a further decline from those prevailing in recent weeks; it was, however, equal to 4.3 in Hull and 7.5 in Preston. The largest proportional fatality of scarlet fever occurred in Sunderland and Derby; of

whooping-cough in Manchester and Oldham; of measles in Sheffield and Sunderland, and of "fever" in Sunderland and Derby. Of the 24 deaths from diphtheria in the twenty-eight towns, 17 occurred in London, and 4 in Leeds. Small-pox caused 5 deaths in Newcastle-on-Tyne, 2 in Nottingham, and 2 in the suburban districts round London. The number of small-pox patients in the metropolitan asylum hospitals, which had steadily declined from 114 to 84 in the three preceding weeks, further fell to 79 on Saturday last; 13 new cases of small-pox were admitted to these hospitals during last week, against 9 and 10 in the two previous weeks. The deaths referred to diseases of the respiratory organs in London, which had been 178 and 192 in the two preceding weeks, further rose to 263 last week, and were 61 above the corrected weekly average. The causes of 85, or 2·5 per cent., of the deaths in the twenty-eight towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Brighton, Portsmouth, and in four other smaller towns; whereas the proportions of uncertified deaths were largest in Wolverhampton, Oldham, Preston, Bradford, and Sheffield.

#### HEALTH OF SCOTCH TOWNS.

The annual death-rate in the eight Scotch towns, which had been equal to 20·1 and 20·9 per 1000 in the two preceding weeks, declined to 18·1 in the week ending the 23rd inst., and was 2·7 below the mean rate during last week in the twenty-eight large English towns. The deaths referred to the principal zymotic diseases in these Scotch towns were but 83 last week, and showed a further decline of 20 from recent weekly numbers; they included 34 from diarrhoea, 13 from whooping-cough, 13 from scarlet fever, 12 from "fever," 9 from diphtheria, 2 from measles, and not one from small-pox. The death-rate from these principal zymotic diseases averaged 3·5 per 1000 in the eight towns, and slightly exceeded the rate from the same diseases in the large English towns. The highest zymotic death-rates occurred last week in Glasgow and Dundee. The 34 deaths attributed to diarrhoea showed a further decline from recent weekly numbers, but included 12 both in Glasgow and Dundee. The 13 fatal cases of whooping-cough, of which no fewer than 11 occurred in Glasgow, also showed a decline from the numbers in recent weeks. The deaths from scarlet fever, on the other hand, which had been 11 and 10 in the two previous weeks, rose to 13 last week, and included 9 in Glasgow and 2 in Edinburgh. The deaths referred to "fever" were more numerous than in any recent week; 5 were returned in Glasgow and 3 in Dundee. Five of the 9 fatal cases of diphtheria occurred in Glasgow. The deaths referred to acute diseases of the lungs in the eight towns, which had been 61 and 70 in the two previous weeks, further rose to 72 last week, but were fewer by 6 than those attributed to the same diseases in the corresponding week of last year.

#### HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 27·6 and 25·8 per 1000 in the two preceding weeks, was 26·1 in the week ending the 23rd inst. During the first twelve weeks of the current quarter the death-rate in this city averaged 23·1 per 1000, against 18·5 in London and 17·8 in Edinburgh. The 174 deaths in Dublin last week showed an increase of 2 upon the number in the preceding week; they included 10 which were referred to diarrhoea, 4 to "fever," 3 to whooping-cough, 2 to measles, 1 to scarlet fever, and not one either to small-pox or diphtheria. Thus 20 deaths resulted from these principal zymotic diseases, against 28 in each of the three preceding weeks; they were equal to an annual rate of 3·0 per 1000, while the rate from the same diseases was 2·8 in London and 2·0 in Edinburgh. The fatal cases of diarrhoea, which had been 17 in each of the two previous weeks, declined to 10 last week, but were equal to a rate considerably exceeding that which prevailed either in London or Edinburgh. The deaths referred both to "fever" and whooping-cough showed an increase upon the numbers in the previous week. No fatal case of diphtheria was recorded, although 3 were returned in the preceding week. The deaths of infants showed a considerable increase upon those in the previous week. The causes of 30, or 17 per cent., of the deaths registered during the week were not certified.

### THE MINUTES OF EVIDENCE BEFORE THE ROYAL COMMISSION ON MEDICAL ACTS.

#### THE INEQUALITY OF THE MEDICAL AND SURGICAL EXAMINATIONS.—(Continued.)

##### Examination of Dr. R. H. SEMPLE.

3669. (*Professor Huxley.*) I understand that, to a large extent, the same young men who come to the Society of Apothecaries also go to the College of Surgeons?—I do not know, but I think so, though, as I have said, a great many come up from other bodies. For instance, one comes from the Royal College of Physicians of Edinburgh, and another from the Royal College of Surgeons, Edinburgh, another comes from Calcutta, and others come from the Faculty of Physicians and Surgeons, Glasgow. These men do not go through the London College of Surgeons at all; a great many also come from India, Australia, and all parts of the world, and do not pass through the College of Surgeons.

3670. Can you explain to us why it is that so large a number of young men come to you for your final examination who do not come to you for your earlier examinations? You have told us that a large number do come for the final who do not come for the earlier examination?—First of all, many consider it too severe. There are men who regard chemistry as a kind of *pons asinorum*, and avoid it by all the means in their power; but some of those men go to the College of Physicians of Edinburgh, and get over the chemistry somehow or other, or to the Faculty of Physicians and Surgeons of Glasgow. At any rate, they get over the chemistry somehow, and then they come back.

3671. Would you say that the examinations are at present conducted in such a way that candidates exercise a certain power of selection as to the bodies they should go to for particular stages of their examinations?—Decidedly so.

##### Examination of Mr. CHRISTOPHER HEATH.

3991. (*Chairman.*) Has your experience taught you that there is any considerable difference between the examinations of the various licensing bodies?—Certainly, men who fail here can go and get a diploma elsewhere.

3992. Are the examinations of all the English licensing bodies nearly the same?—There is a great difference in the different boards in England, of course, but men who fail at the examinations of the College of Surgeons can go and get a diploma elsewhere.

3993. Where do they generally go?—To Glasgow by preference, and sometimes to Edinburgh.

3994. Not to the Edinburgh University I presume?—No, the double licence of the College of Physicians and College of Surgeons at Glasgow is considered the easiest, and next to that is the double licence of Edinburgh.

3995. Have you yourself any knowledge from experience of the examination of the Glasgow Faculty?—I only judge by the results, I know that men who go up, who failed here, come back with diplomas.

3996. You know from your own knowledge instances of men who have failed here in the examinations of the College of Surgeons and who have gone to the Faculty at Glasgow or the College of Edinburgh, and obtained diplomas?—Yes.

3997. Have you known many such instances?—A good many scattered over the last twenty years.

3998. Could you give us one or two particular instances without mentioning the names?—I may mention one which occurred two years ago. A man was plucked the third or fourth time at the primary examination at the College of Surgeons in anatomy and physiology, he afterwards, at my recommendation went to Glasgow, and came back with a double qualification. (The witness gave the details of this case.)

3999. Can you give us any other instance?—Yes. (The witness gave the details of another case.)

4000. Have you known many such cases?—Yes.

4001. And do they occur constantly?—I do not say they occur constantly, but I have known a good many cases in twenty years.

4002. And you had no doubt in your own mind that the examinations of those two licensing bodies are considerably easier than certain of the examinations of the two London corporations?—I have no doubt whatever of it.

4003. Do you consider that the examinations of the two London corporations are at all too high?—I think they are being screwed up too much, I must say, in the early subjects.

4004. In what respects?—For men who have got to get their living by practice and are badly paid, too much scientific knowledge is expected of them.

4005. In what sciences?—In physiology particularly, and minute anatomy, or you might say histology.

4031. (*Professor Turner.*) Are you acquainted with the regulations of the Royal College of Surgeons of Edinburgh admitting candidates to the examination of that body?—No, I cannot say that I am.

4032. Would you kindly read regulation 17 (handing a book to the witness)?—"No candidate shall be admissible to examination who has been rejected by any other licensing board within the three months preceding his application to be examined."

4033. Those candidates you have referred to, who were rejected by the College of Surgeons in England, must have allowed three months to elapse before they were admitted to the examination of the College of Surgeons of Edinburgh, and a similar regulation prevails in the Edinburgh College of Physicians and in the Glasgow Faculty?—I suppose so.

4034. Then presumably those rejected candidates were engaged in study during the subsequent three months?—I think I could give a case to the contrary in which the greater part of the three months was vacation.

4035. Still a student, although it may be vacation as regards the schools, may be engaged in private study?—Yes.

4036. You yourself in the earlier part of your career were a good deal engaged, were you not, in preparing students for examination?—Yes.

4037. I suppose you found you could do a great deal in three months?—Yes, a great deal.

4038. Is it at all unlikely that those candidates remitted by the College of Surgeons of England, spending, we will say, those three months in study, had added very materially to their stock of information?—I do not think that they had. I do not think that some men that I knew were capable of doing it; and I am certain that in one particular instance the man could not have added much to his information.

4039. Is it your opinion that those persons you have referred to were really incompetent persons in the subjects on which they were examined?—I think they were men of inferior intellects certainly.

4040. Do you think that they were such persons as should not be admitted to practise medicine?—I do not say that; that is a very wide question.

#### *Examination of Mr. C. MACNAMARA, F.R.C.S. Eng.*

4124. (*Bishop of Peterborough.*) To what do you attribute the greater ease with which men can get into the medical profession here than elsewhere?—Clearly because if men fail here in one examination they pass to another and less stringent examination in some other part of the country.

4125. Have you known as a matter of fact in your own experience cases of students who have failed in one examination and have sought another?—I have.

4126. And those students have got in in the second case because the examination was easier?—Yes, they have.

4127. And is that the opinion generally of those practitioners with whom you are in relation?—Unquestionably.

4128. It is very strongly the opinion of the profession, is it not, so far as you know it, that it suffers from the too great ease with which men can obtain a licence to practise?—Unquestionably.

4129. And also that that too great ease arises from the fact of there being so many licensing bodies?—Precisely so.

4130. That opinion is not only your own, but it is held generally by the profession?—I believe it is.

#### *Examination of Mr. HENRY MORRIS, M.B., F.R.C.S., Lecturer on Anatomy, in the Middlesex Hospital, and formerly engaged in preparing Students for the Professional Examinations.*

4588. (*Chairman.*) Of course you must of necessity be very familiar with the different examinations of the different licensing bodies; in preparing young men formerly you must have found, I suppose, that there is a considerable difference between the examinations of the different licensing bodies?—Yes, certainly.

4589. And should you say that the standard was the least

high in London, or in the provinces?—My experience was almost limited to the several examinations held by the different bodies in London, so that I could not compare from a teaching point of view the London examinations with the examinations in Scotland or in Ireland for instance.

4590. Do you remember any instance of persons who could not pass the examinations here and who went to Scotland or to Ireland?—Yes, many; but some of the instances that one has known of students going to Scotland or elsewhere for the examinations have not been altogether on account of the difference in the severity of the examinations of the different bodies, but for other reasons.

4592. You are now speaking solely with regard to the universities. I do not suppose you would say from your experience that persons who have failed here to pass the examinations have gone to the Scottish universities?—No.

4593. They go there to pass some of the examinations of the corporations?—Exactly so.

4594. But have you known instances of persons who have gone north for the examinations of the corporations on that account?—Certainly.

4595. You would say it is quite notorious that such things exist?—It is notorious in the schools both in London and elsewhere, I think.

4596. And with regard to the examinations in London, what examinations, should you say, are the least high in London?—That of the Apothecaries' Hall undoubtedly.

4732. (*Mr. Cogan.*) Are not some of the bodies notorious for giving very easy examinations in anatomy?—Yes, they are.

#### *Examination of Professor W. T. GAIRDNER, M.D.*

4802. (*Mr. Cogan.*) Do you believe that at present there is any injurious competition—I mean injurious to the public—arising from the number of licensing bodies?—I believe that has been, at all events, very much exaggerated. I am not prepared to say that there have not been instances where licensing bodies have been weak, but I think that that has been very much exaggerated.

4803. If evidence has been given to us that many students who could not pass the test of some licensing bodies went to others for the purpose of passing a lower examination, and did successfully do so, would you believe that that was an evil?—If it were a general practice it certainly would be a public evil. It might happen with any individual student, or with two or three students, without being necessarily a fault.

#### *Examination of Mr. THOMAS COOKE, F.R.C.S. Eng., M.D. Paris.*

In answer to the Chairman Mr. Cooke said he had had large experience in preparing young men and practitioners for various examinations.

4899. (*Chairman.*) Are you aware of a considerable difference in the severity of those examinations?—There is a very great difference in the severity of the several examinations; the difference is tremendous. As regards the Scotch examinations, I should not be in a position to speak of them individually. I can speak of the Scotch examining bodies in general. I should not be in a position to speak of them in particular, and to compare, with any positive data, Edinburgh to Glasgow or Glasgow to Edinburgh.

4900. You are speaking of the corporations?—I am speaking of the corporations.

4901. Will you give us your own idea of the relative severity of those examinations?—The Scotch examinations are, I think, very fair; they are thoroughly good practical examinations taken all round. Men who are insufficiently prepared do not pass them. They are thorough and searching examinations; and, at the same time, my experience is that ample time is allowed to the candidate to show what he really does know. I think they are very good examinations in every respect as regards the average student, that is as regards the student who is to become the general practitioner. I should except the M.D. of St. Andrews. I have a special note on that point.

4902. I thought we were speaking of the examinations of the Scotch corporations only. I was not referring to the Scotch universities. Should you say that the examinations of the Scotch corporations were as difficult as those, for instance, of the Royal College of Surgeons in England?—No; and yet in one sense they are. There are some men who would pass the examinations of the Royal College of Surgeons of England who would possibly not pass the Scotch

examinations. At the same time there would be a large number of men who would pass the Scotch examinations who would not pass the examinations of the Royal College of Surgeons of England.

4903. Will you explain how that would occur?—The man of good average capacity and ability, who has worked fairly during the whole of his time, and acquired a good practical knowledge of his subjects, I hold to be fairly certain to satisfy the Scotch examiners; and, I think, he would usually satisfy also the examiners in Lincoln's-inn-fields; but it is rather the brilliant and the sharp man, the man who has read a good deal, who has possibly a more, I will not say superficial knowledge, but still a more showy knowledge of details, who would be particularly successful at the Royal College of Surgeons. For the examination of the Royal College of Surgeons both a good practical knowledge and also, if I may say so, a showy knowledge, or a knowledge of little points, is frequently of value, and may turn the scale in favour of a man.

4904. Have you ever known cases in your own experience in which young men who have failed to pass the English examinations went to Scotland and passed the corporation examinations there, or *vice versa*?—I have known a great many who, having failed in London, have gone to Scotland and passed. There are a great number who do that.

4905. Is that a common case?—It is.

4906. Have you known many come from Scotland to pass in London?—I have not known many. At the same time it is but fair that I should state that I meet with a large number of London students, while I meet with a relatively small number of students from Scotland; so that the figures I should have would scarcely establish the proportion between those who go from London to Scotland and those who come from Scotland to London. I think I can say, indeed I am sure I can say, a large number who are not successful here, who fear to face the examination here, go to Scotland.

4907. Taking a large number, what should you say was the general reason why the average of them, having failed in London, succeed in passing in Scotland?—Several reasons may be given. The examinations in Scotland are less hurried, and they are more thorough. It frequently happens that men get nervous or flustered at the London examinations; and as the time is rather short, if a man gets flustered at the first table, he has scarcely time to recover himself sufficiently to show what he really does know.

4908. How long is occupied in an examination in London?—The time has been lengthened, and now, I think, the candidates have a quarter of an hour or twenty minutes at each table; I would not be very positive, but the time is on the whole rather short.

4909. And how long have they at the Scotch corporations?—I could not give the precise figures.

4910. I merely mean in a general way?—The impression on my mind is that they are less hurried, and I have no doubt that that is the case. The number of men examined is less at a time. Anyhow, as regards Glasgow, a man giving notice of his desire to be examined can frequently have a special examination, and therefore be less hurried.

4911.—How do the examinations of the Apothecaries' Society of London compare with those of the College of Surgeons of London?—I believe it would be very difficult indeed to compare the two, they are so very dissimilar. The examination of the Apothecaries' Hall of London is a good examination as regards the compounding of medicines and the mere ordinary uses of medicines; but in all other respects I hold it to be totally insufficient to establish a man's ability to practise medicine or surgery.

4952. (Professor Turner.) Then you leave your pupils to select for themselves the examining board to which they will go?—Entirely so, and the time at which they will go up for examination.

4953. You used the expression that some of the pupils feared to face the examination here in London; at the College of Surgeons, I apprehend, you mean?—Yes.

4954. And then you said they went down to Scotland?—Yes.

4955. Did that mean that they had been rejected at the examinations here and then went down to Scotland, or that they dreaded that the examinations here might be too difficult for them?—The two things would be comprised in my statement. Some had been rejected, and some felt certain, and I may say those who knew them felt certain, and I myself felt certain, that they were not sufficiently prepared, and that they would probably be rejected.

4956. I suppose you know that the Royal College of Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow conduct an examination which covers a much more extensive range of subjects than the examination of the Royal College of Surgeons of England?—Quite so; you refer, I believe, to the double qualification, do you not?

4957. No, I refer to the examinations conducted by the College of Surgeons and the Faculty of Physicians and Surgeons in Glasgow for their ordinary diplomas?—I have known men very deficient in chemistry. That is one of the subjects required at Edinburgh, which is not required here. Men go to what they consider the trouble of getting up chemistry, in order to be able to present themselves at the Scotch examinations.

4958. With reference to the youths who have shown this fear of facing the examinations in London, are we to understand that they are in your judgment, so far as you have the means of knowing what their information is, persons who ought not to be admitted to the ranks of the profession?—No. I do not say that.

4959. In some respects I gathered that you hold that the examinations of the corporations in Scotland are conducted in a fairer and more judicious way than the examinations of the College of Surgeons of London?—In a more uniform and more reliable way as regards the results, that is the results of the pass and the pluck. I could feel much more sure that a man fairly well up in his work would pass at the Scotch examinations than that the same man, or even a more brilliant man, would pass the English examinations.

4960. Because the examinations in Scotland, you think, are conducted in a less hurried way, and are better adapted to bring out the knowledge of the candidate?—I think so.

(To be continued.)

## THE SERVICES.

Deputy Surgeon-General Herbert Reade, V.C., has been transferred from the Eastern District, Colchester, to Plymouth, as Principal Medical Officer of the Western District, vice Deputy Surgeon-General J. Lamprey, proceeded to Cyprus with the Egyptian expedition.

Deputy Surgeon-General Murphy has been appointed to the Eastern District on return from Ceylon.

Brigade Surgeon Veale is on passage from Egypt in the hospital ship *Carthage*, having been invalided from Ismailia. Dr. Veale was suffering from dysentery.

H.M. troopship *Malabar* arrived at Portsmouth on the 25th inst., with a large batch of sick and wounded from Egypt. Surgeon-Major R. Anderson was in medical charge of the vessel, with Surgeons Anthonisz and Lane. The sick were transferred to Netley Hospital. Two deaths occurred shortly before the vessel left the Canal: one, a private of the Army Hospital Corps, from dysentery.

YEOMANRY CAVALRY.—Buckinghamshire: Surgeon Henry Walter Kiaulmark is granted the honorary rank of Surgeon-Major.

ADMIRALTY.—Fleet Surgeon John Sampson Lewis, M.D., has been placed on the Retired List of his rank from the 25th instant; Staff Surgeon William Graham to be Fleet Surgeon in Her Majesty's Fleet, with seniority of the 20th instant.

The following appointments have been made: Fleet Surgeon William H. Cruice, to the *Eagle*, vice Lewis; Surgeons Michael J. McCarthy, M.D., Andrew D. Peyton, and Staff Surgeon James H. Martin, to the *London*; Staff Surgeon John Allan Robertson, to the *Heroine* (appointment of Edward W. Doyle cancelled); Fleet Surgeon James N. J. O'Malley, additional, to the *Duke of Wellington*; Fleet Surgeon William S. Fisher, to the *Euryalus*, vice Strickland.

UNWHOLESOME MEAT.—At the West Ham Police Court, Stratford, on Wednesday last, an application for an order to destroy more than a thousand carcasses of sheep in a putrid condition was made by the Port of London Sanitary Inspector, Mr. Gilles. Evidence having been given by Dr. Collingridge, the medical officer of health, to the effect that it was unfit for food, the stipendiary magistrate, Mr. Phillips, granted the order asked for. The meat was brought from Egypt by the *Orient*, and was lying in the Victoria Docks.

"Audi alteram partem."

## "WOOD PAVEMENT."

To the Editor of THE LANCET.

SIR,—Professor O. W. Wight, Health Officer of Detroit, U.S.A. (THE LANCET, Sept. 23rd, p. 513), describes wood pavement as laid in America, and utterly condemns it, and most deservedly; but then the mode of construction described is wrong in every way it is possible to be. Wood pavement should be constructed as under—namely, the foundation should be absolutely sound, watertight, and have a smooth and even surface. In England such foundation is best made of Portland-cement-concrete, the surface finished with neat cement; over this surface should be laid a layer of tar-felt, or a layer of asphalt, not less than half an inch in thickness. The wood blocks should be sound and free from sap, if creosoted all the better. The blocks should be laid solidly on the prepared base, and, with a layer of tar-felt betwixt, be close jointed. The surface of any wood pavement so laid will be smooth and absolutely watertight, and in wear will not be subject to any of the ills attributed to the wood pavements as laid in America and as described by Professor Wight. The wood pavement as herein described will, in England, cost from 12s. to 14s. per square yard, according as the foundation may have been more or less costly. The felt used will cost 2s. per square yard. Wood paving has been most imperfectly laid in London, and has greatly discredited the system. There are, however, now good samples—as in Parliament-street and St. James's-street, for instance.

The bad examples of America must have been followed in England, and especially in London at first: such as loose and ill-formed foundations with blocks set wide apart, the spaces filled in with gravel or with concrete. In these cases the foundations gave way, the blocks frayed at the edges and sunk, the whole surface becoming uneven and jolting with less than twelve months' wear. When wood blocks are laid on a solid and smooth foundation, and are close jointed, they cannot sink or fray at the edges, but must wear evenly, because the traffic passes over smoothly. Such surfaces may be washed by hose and jet so as each morning to be clean and sweet as when new. London under uniform municipal government may accomplish this.

I am, Sir, yours faithfully,

September 25th, 1882. ROBERT RAWLINSON, C.B., &amp;c.

## THE COMPULSORY NOTIFICATION OF INFECTIOUS DISEASES.

To the Editor of THE LANCET.

SIR,—The newspaper reports of the proceedings of the Public Health Section of the Social Science Congress contain a statement that a resolution was adopted by the section in approval of the principle of Mr. Hastings' Bill, which proposes that the medical attendant shall be compelled by fine or imprisonment to report to the sanitary authority every case of infectious disease coming within his knowledge. Lest it may be assumed that the section gave its deliberate sanction to this proposal, I think it well to inform you of the exact circumstances. After a debate, which lasted four hours and a half, and in which the speakers against the proposal were almost as numerous as its advocates, a motion was unexpectedly proposed, no notice whatever of it having been given. The motion declared that the section endorsed Mr. Hastings' Bill, which was not before the section at all, had not been even mentioned in the debate except by the mover, and was entirely unknown to the great majority of those present. As it was manifestly improper that the section should be pledged to approval of a measure of which it was ignorant, I desired to move the previous question as an amendment, and if I had been permitted I am satisfied that my motion would have been carried by a large majority. To my astonishment, it was ruled by the chairman that no amendment of any sort could be entertained, and that a Yes or No vote should be taken on the merits of Mr. Hastings' proposal. Such a

question being put from the chair, the great majority of those present declined to vote, and a small minority of the section decided the question affirmatively. No doubt use will be made of this vote to support Mr. Hastings' Bill in the next session of Parliament, but I think it will be agreed that an expression of opinion, forced without notice, and without permitting any alternative proposition to be considered, is entirely valueless. And I am further of opinion that the ruling of the chairman was altogether unconstitutional, and at variance with the usage of the Congress or any other public assembly.—I am, Sir, yours &c.

ARCHIBALD H. JACOB, M.D., F.R.C.S.

Ely Place, Dublin, September, 1882.

## THE QUEEN'S UNIVERSITY DEGREES.

To the Editor of THE LANCET.

SIR,—In your issue of the 23rd inst. I notice a statement made before the Royal Commission on Medical Acts, by Dr. Jacob, of Dublin, where, among other things, he says, referring to the affiliated Colleges of the late Queen's University, "A student attending in a Queen's College may obtain all the lectures necessary for a Queen's University degree (or a Scotch double diploma) in two years." Now, as to the requirements for a Scotch double diploma I know nothing; but regarding the Queen's University, I know that Dr. Jacob's statement is not a fact. It may be a great annoyance for any medical man to be called on to give evidence before a Commission, but if he consents he ought to feel bound at least to be accurate in his statements irrespective of results. The Calendar of the University will prove the truth of my statement; but, in a word, I may just show the impossibility of what Dr. Jacob states. The University requires twenty-four full months' attendance at hospital, and as it is only possible to attend nine months in each year, it will be evident that two years will not suffice, but that it will require three winter terms of six months each and two summer terms of three months each, or, in other words, three years. Besides this, no student can attend hospital during his first year, as he is obliged to be present at College lectures during the roll-call at hospital, and cannot secure "a present" at both places. This brings out a further fact, that each student must therefore begin his hospital attendance after his first year at College, and can thus only secure the necessary certificates in three years and a half.

Dr. Jacob suggests that the reason so many Queen's University students go to Scotland for qualifications—and everyone must admit the proportion is large—is because the term of study at Queen's Colleges is very short. This I have shown not to be a fact. The true reason is this, Queen's University degree is admittedly difficult to obtain, and this Dr. Jacob must know, there being only one-fourth of the students who enter the University who ever obtain its degree. And, as a matter of fact, Dr. Jacob perhaps also knows that students failing at Queen's University go to either the Scotch licensing bodies or to the Royal College of Surgeons, Dublin, and obtain their qualifications.

I am, Sir, yours &amp;c.,

London, Sept. 26th, 1882.

J. W. M.

## SUDDEN DEATH AFTER DIPHTHERIA.

To the Editor of THE LANCET.

SIR,—The case related by Mr. Alfred Charlton in last Saturday's LANCET reminds me of one which came under my observation in 1874, when I was acting as locum tenens for Dr. R. Lowther, of Cartmel, in Lancashire. Diphtheria of a severe type had carried off several members of one of the leading families in the place. Amongst the survivors was a young lady, whose age I do not recollect, but probably about thirteen or fourteen, convalescent as far as general symptoms were concerned, but suffering from precocious pharyngeal paralysis, which rendered deglutition of a sufficient quantity of food impossible. For a week or ten days she had been living upon nutrient enemata, but she was beginning to swallow with greater facility, and appeared in a fair way of recovery, when death occurred in the following manner:—A bedpan, which she required to use for the purpose of defecation, had been slipped, without causing her any exertion, beneath the clothes; but some difficulty taking

place in the passage of the motion, she was in the act of raising herself slightly by the arms, when she fell back dead.

Post-mortem examinations show that the heart in diphtheria is often affected with fatty degeneration, and one of the causes of sudden death is paralysis, or failure of the cardiac muscle. In other cases a fibrinous clot may be found either in the heart itself or in the large vessels.

I am, Sir, your obedient servant,  
Oscar Jennings, M.D.  
Paris, September 25th, 1882.

### "ETIOLOGY OF DIPHTHERIA."

To the Editor of THE LANCET.

SIR,—I read with great interest the report of the outbreaks of diphtheria at King's Lynn, Sale, and Sutton-in-Ashfield, reported in last week's LANCET, and commented upon by you in a leader, as throwing some light on the etiology of an outbreak here, which has haply been to all appearance stamped out, or died a natural death.

Harrow Weald is hilly and woody, lying to the north of Harrow, with a clay soil, the clay extending from twenty feet to forty feet below the surface; has no river or canal. Without making a lengthy report of separate cases, I will remark that the disease seemed to be propagated amongst the children attending the parish schools; but no cause could be discovered by the medical officer of health to account for the outbreak. The schools, however, were closed, but the disease increased. A thorough investigation of the houses at which the disease was rife threw no light on the etiology of the outbreak; milk, water, drains, &c. did not account for it, and had I not seen the report of the outbreaks referred to would have had to be content with suppositions. A sewerage system for Pinner and Harrow Weald has lately been commenced and new pipes laid at a depth of twenty feet below the surface, throughout the whole of the districts, making altogether a length of eight miles. The old pipes have not been interfered with in any way, nor have the new ones been yet connected with any house, thus sewage matter has not been exposed, and so the outbreak was not connected with the new scheme.

The question therefore is, Have some long-buried germs of some indigenous diphtheria, causing microzymes, been unearthed, and, aided by season and atmosphere, given rise to a fresh outbreak? The outbreak was preceded by (one might call it) a "mumps" epidemic, which, I am convinced, was true mumps, and not mild cases of diphtheria. I had no case of scarlatina or measles. None of the men at work on the excavations had the disease; but this is in no way strange, as children are much more liable to it than adults. The only two cases of adults having diphtheria that I had seen to have caught the disease by direct infection from nursing children suffering from it; the disease, however, takes a much more malignant form in adults.

With regard to the action of diphtheria on the heart much remains to be discovered; several patients, some seemingly convalescent (although I notice it only occurs in those who have the more malignant form of the disease), complain suddenly of violent pain in the cardiac region, and as suddenly expire. Can any theory be suggested about this? Although the symptom is mentioned in some text-books, I have never seen an attempted explanation.

I am, Sir, yours obediently,  
PERCY POPE, M.R.C.S., &c.,  
Medical Officer, Pinner and Harrow Weald Districts.  
Pinner, September 25th, 1882.

### NEWCASTLE-ON-TYNE.

(From our own Correspondent.)

OUR very modern "city," but very ancient town, has lately become a centre of attraction since the "Congress season," which has—as has been humorously said—"set in with its usual severity." It may not be known to all your readers that we have at Tynemouth now an exhibition of naval architecture, fishery appliances, and machinery, exhibiting the manufactures of the district from Armstrong guns and steam dredgers to Swan lights and swing bridges, and life-saving apparatus—indeed, I might say, that all machinery connected with the sea, and much of what is

connected with the land, has a temporary home and resting-place at the beautiful aquarium at Tynemouth. This rising watering-place is to all intents and purposes a suburb of Newcastle, being reached by rail in a very few moments. The success of this exhibition has exceeded all expectations; 18,000 persons have visited it on a single day, and for the short time it has been opened 100,000 persons have passed in. I would strongly advise all who have the opportunity to pay it a visit, as there is much to interest a medical visitor.

The above great attraction and the Sanitary Institute of Great Britain Congress have crowded our city with visitors. The Congress began yesterday, and "made a good beginning," most travellers would say, by a public luncheon at 1 P.M., while at 3 P.M. the exhibition was opened. This, of course, is an exhibition in our city of sanitary apparatus and appliances, and is quite distinct from the one before mentioned at Tynemouth. It is really a wonderful collection, from all parts of the empire and the Continent, of objects connected with health, such as baths, lavatories, heating, cooking, lighting, ventilation, feeding, clothing, filtering, disinfecting, *et hoc genus omne*. Lectures on cooking are to be given daily, while prizes and certificates are to be awarded by competent judges. Our *confrères* here have made due arrangements for all professional and lay visitors who wish to see our medical institutions. At the Infirmary (250 beds) the physicians and surgeons will conduct professional visitors, while the house-governor and house-surgeons will conduct other members of the Congress. Our city is fully supplied with special medical institutions; I need only mention the Child's Hospital, the Women's Hospital, the Eye Infirmary, the Skin Hospital, Hospital for Diseases of the Chest and Throat, and Ear Hospital, the staff of which will be glad to receive and conduct members of the Congress. Those who go down to Tynemouth cannot do better than run on to Whitley and visit the noble Convalescent Home (135 beds), with which the name of our esteemed townsman, Dr. Philipson, is so intimately connected. It is modestly called "Home," but at first sight, and afterwards, indeed, from a structural point of view, it might be fitly called a castle or a palace. On Tuesday also the visitors were invited, and had special conveyances provided to take them, to the interesting works of Sir William Armstrong at Elswick, where they witnessed the various processes in this great factory; but the real business may be said to have begun on Tuesday night, when the President, Captain Douglas Galton, F.R.S., gave his address. I can only here give you the heads of this discourse, but even that will show the ground it covered and the importance of the matters touched upon—viz., "Disease conveyed by germs," "Germs in the air," "Germs in the blood," "Germs in the soil," "Germs in fever," "Our countless enemies," "Robust health our defence," "Isolation of fever cases," "Mysterious movements of epidemics," "Impure water," "Impure air," "Sewerage works valuable," "Dust in the air," "The value of sanitary measures," and so on, I might say, on the whole sanitary question in all its bearings. The address was one of "a master," and was listened to with much attention. All our daily papers give it much prominence and discuss its many aspects.

To-day we are promised the following papers and discussions thereon:—In the Section of Sanitary Science and Preventive Medicine: Address by Dr. Embleton. H. E. Armstrong, Esq., our active city officer of health: Sketch of the Sanitary History of Newcastle-on-Tyne; with maps and illustrations of ancient and modern Newcastle. Dr. Alfred Carpenter: The Sanitary Aspect of Dress. Dr. Benjamin Browning: The Effects of certain Paint and Colour Manufactories in London on the Health of the Producers. Captain R. Hildyard: The Influence on Sanitary Progress which Medical Men might exercise in their Private Practice. Dr. Lediard: Arsenic in Domestic Fabrics. Dr. A. E. Harris: Infantile Mortality. Miss Yates: Bread Reform. Then there is to be a conversazione in the afternoon, and another in the evening, which I may call in advance a brilliant one, as the electric light is to be used freely. This entertainment is given in the City Hall, by invitation of our mayor and corporation. So far the Congress has been very successful, and the arrangements made have been most complete and thoughtful; this has been brought about by many willing workers, but especially by the endeavours of Dr. Mears of the Newcastle College of Medicine, and Mr. H. E. Armstrong.

In my letter of next week I hope to report to you the

further proceedings of the Congress; also something more about the exhibition and its contents; while I have been invited to the opening of the College of Medicine here in connexion with the University of Durham, which takes place on Monday, October 2nd.

Newcastle-on-Tyne, September 27th, 1882.

## SCOTTISH NOTES.

(From our own Correspondent.)

A PROPOSAL is at present being considered by the profession in Fifeshire that a medical association should be formed for the county. The object of the association would be to confirm and strengthen the *esprit de corps* which should exist among the members of a liberal profession, and it is intended that the meetings should be held annually in St. Andrews, Cupar, Kirkcaldy, and Dunfermline in rotation. Very satisfactory progress has already been made, nearly fifty members have agreed to join, and the association will be formally launched at a meeting to be held this week in Cupar, under the presidency of Professor J. Bell Pettigrew of St. Andrews. The inevitable dinner will follow the meeting, at which Dr. Pettigrew will deliver an inaugural address.

Dr. Keith's ovariectomy statistics have gained for him the very highest position as a practical surgeon, while his absence of all that approaches self-laudation is equally conspicuous. When he chooses to publish the results gained by him in the newer operation of hysterectomy or removal of the uterus, with or without its appendages, he is likely, judging from his experience so far, to enhance his fame. The enormous mortality in some hands, and the high average when all the cases so far published are considered, make Dr. Keith's present success almost phenomenal. I believe that up till now he has operated in thirteen cases with but one death. One of the last of his patients presented such unpromising features that her ordinary attendant, as well as the gentleman who saw her while in the country previous to the operation, felt confident that she was unequal to the shock of the operation, and their views were made known to Dr. Keith. The state of anæmia, the weak if not diseased heart occasioned by the profuse discharge at each frequently recurring period, as well as other debilitating influences, made the prognosis so exceedingly grave that there seemed almost no hope. But of all this Dr. Keith was equally well aware, while he also knew that there was absolutely no chance of his patient surviving the menopause, still several years off. He removed the uterine mass, which, with the appendages, weighed over nine pounds. The patient had an uninterrupted recovery, and I hear from her former attendant that at the end of five weeks she has been sent to the coast to complete her convalescence. When Dr. Keith gives his results we may feel confident that the fear of injury to his statistics has not deterred him from operating in any case.

The Trades Union Congress resolved at their meeting in Manchester last week to agitate in favour of open inquiry into all cases of sudden and accidental death in Scotland. From other quarters the Lord Advocate has been urged in the same direction; but it will be strange if public opinion in Scotland be found favourable to coroners' inquests. Their remarkable verdicts in England have not generally been considered elucidatory in complex cases, whereas the skilful methods of the Procurator Fiscal, commonly assisted by competent medical men, have left few loopholes for the guilty, while causing a minimum of irritation when no guilt is found. When a post-mortem examination is required, in the vast majority of cases little further inquiry is necessary, a satisfactory explanation is afforded, and further expense is saved.

Though usually highly appreciated in Scotland, it appears that at least two of the many hydropathic institutions recently built have had to succumb for want of support. One in the immediate neighbourhood of Edinburgh has been bought at a very small proportion of the original cost, and will now be converted into a good class school; while it appears that the indefatigable Miss Clugston is anxious to possess herself of the Kilmacollum Establishment, that she may institute a home for convalescents or incurables. This

is so much against the wishes of the villagers and villa residents that they have determined upon united action, and will, if possible, raise sufficient capital to purchase the building.

An enthusiastic meeting of the leading inhabitants of Hawick was held last week, when it was determined to establish a "Technical and Scientific College for the South of Scotland" in that town. Considering the good results already attained by the science class, with its insignificant accommodation, we may anticipate a useful institution, if Hawick can but obtain the sympathy and support of the neighbouring towns. A large sum of money has already been guaranteed.

In the eighth line of my last week's Notes the word "rainfall" should read *rain-band*. The prediction there alluded to was by Mr. Piazzi Smyth, the Scottish Astronomer-Royal, and it has since been much commented on. The Duke of Argyll especially records observations which go to show that such hits as that made by Mr. Smyth with the spectroscope are not likely often to follow the use of that instrument, at least till the conditions affecting the rain-band are more fully understood, and its true value among other factors is better known.

## IRELAND.

(From our own Correspondent.)

DURING the session 1881-82 there were in the Queen's College, Cork, 279 matriculated students and 23 non-matriculated, or a total of 302 in the Faculty of Medicine. Of these 106 were new entries, while the total number of students on the books of the College was 402, as contrasted with 327 in the preceding session. In last February the Queen's University was dissolved, and its graduates made graduates of the Royal University of Ireland, a change which the President is of opinion will act injuriously on higher education. In consequence of the large increase of students year by year the accommodation in the College buildings has proved inadequate, more especially in reference to the chemical laboratory. The present state of this department is very bad, and the President trusts that the necessary funds for the erection of a new laboratory, for which application was made last year, will shortly be provided. In the previous report the want of assistants to the professors in the experimental branches of science, and of the necessity that existed for increasing the teaching staff in the Faculty of Medicine, were referred to. These wants have become more pressing every day on account of the change which has taken place in the mode of teaching the physical sciences and the increase in the number of students.

On the 5th prox. the Council of the Royal College of Surgeons in Ireland will elect examiners for the diploma in dental surgery. Three of the examiners must be Fellows of the College, and three dentists, registered under the Dental Act, to examine in Mechanical Dentistry.

The introductory lecture at the Royal College of Surgeons in Ireland will be delivered by Dr. Jacob, who was appointed lecturer on ophthalmic and auricular surgery on the resignation of Mr. Swanzy. Mr. Smyly will give the address at the Meath Hospital, Mr. Kennedy at the Mater Misericordiæ, and Dr. Quinlan at St. Vincent's Hospital.

The Hospital for Women and Children, Cork, is an admirable institution, but the present building not affording sufficient accommodation, the board of management have issued an appeal for funds to enable them to erect a suitable hospital. A sum of nearly £1000 has already been obtained, of which £700 has been received from the proceeds of a bazaar.

Considerable regret has been expressed by the untimely decease of Dr. William Thompson, of Lisburn, a surgeon of great skill and experience in the north of Ireland, and who commanded a very large practice. Last week after visiting a patient in Belfast he was returning to his home, and at Danmurry Station he incautiously crossed the line, and while doing so was knocked down by a passing train, which caused such injuries as produced death in a few minutes. The deceased was a M.D. of the University of Edinburgh and a Fellow of the Royal College of Surgeons in Ireland.

He settled in Lisburn some thirty years since, and became connected with the County Infirmary, while his skill as an able practitioner spread far beyond the limits of the locality in which he resided. The funeral took place last Monday, his remains being followed to their last resting-place by a very large concourse. Two of those who helped to carry the coffin from the Cathedral to the graveyard were Dr. Musgrave and Mr. Green, the first and last pupils of the deceased.

A nurse, aged twenty-two, belonging to the Belfast Royal Hospital, died last week from strychnine poisoning. At first her death was attributed to epilepsy, but further inquiries and an analysis of the contents of the stomach proved unmistakably that it was a case of poisoning from strychnine. The poison was obtained from the surgery of the hospital, which, from the evidence, it appeared, was more easy of access than it should have been, but the committee previous to the occurrence had framed new rules relating to its care.

### THE FIFTY-FIFTH MEETING OF GERMAN NATURALISTS AND MEDICAL MEN.

(From a Correspondent.)

THE above Association, corresponding to a combination of the British Association and the British Medical Association, has just concluded its annual meeting at Eisenach, so well known to the English tourist. The meeting passed off very well and, socially considered, was a great success, though its scientific outcome fell short of the expectations of many of the members, and for reasons which are not far to seek. The choice of the place had some share in this, for many preferred to study nature, which presents itself here in all its loveliness, rather than attend the "sections;" but a more powerful cause, and one which, I am afraid, will show itself in all the future meetings, more or less, is the establishment of so many congresses of different special branches of medicine, such as for ophthalmology, surgery, and psychiatry, and recently also for clinical medicine. The meeting was very numerously attended, though many of the best-known clinical teachers of the larger universities were absent, and those few present did not take a very active part in the several discussions. The scientific work done consists of general addresses and sectional meetings. Of the general addresses that of Professor Bergmann (the successor of Langenbeck) was the only one of purely medical interest, and had for its title "The Present Methods of Wound Dressings and their Relations to Antisepticity." It was a popular lecture on the antiseptic treatment of wounds and an appeal to the surgeons not to allow surgery to become merely a technical art, and not to forget other important points, such as the stoppage of hæmorrhage, the condition of the parts in and near the wound, and the process of wound healing. Amongst the other general addresses Hæckel's most lucid and masterly oration on Darwin formed the *pièce de résistance*. That Darwin's greatness and merits were done full justice to by this, the foremost of Darwin's expounders, may be easily imagined. It is impossible to give even an outline of this address, which will appear *in extenso* in the "Deutsche Rundschau" for October. I may, however, mention that Hæckel concluded his speech by showing that the adoption of Darwin's theory may be quite in harmony with religion, and he cited a letter written by Darwin in 1879 to a German student who felt his religious belief shaken by the new theory, and who addressed himself to Darwin.

Dr. Aasmaum's address on "Atmospheric Dust" was a clear, concise, and able *résumé* of all that is known respecting its meteorological, chemical, physical, and hygienic relations.

In the different medical sections there is not much new to record, and the absence, except in the Section for Children's Diseases, of a pre-arranged important subject for discussion is especially to be regretted; there is, however, every likelihood that in future the sectional work will be better managed. Nevertheless, some of the papers read were of more than average interest.

The Gynæcological Section was the most industrious, and

amongst the more important papers read were two by Olshausen; one detailing his further experience on the "Total Extirpation of the Uterus per Vaginam," and the other on the "Treatment of Retroflexion," and one by Professor P. Müller on "Puerperal Atrophy."

In the Surgical Section, presided over at one of its sittings by Langenbeck, Professor König showed a patient in whom he removed the greater portion of the sternum, which was the seat of a rapidly growing osteo-sarcomatous growth. The whole of the sternum, except the uppermost part and the xyphoid process, was removed, and during the operation air entered both pleural cavities, and also the pericardium, which was found adherent to the sternum, and was opened during the operation. The patient made a good recovery, and the wound is now almost entirely healed, except at one point where a portion of an adjacent rib is necrotic and keeps up some little suppuration.

The Section of Pathology, owing to its numerical weakness, had to be merged into the Section for Medicine. Prof. Weigert (Leipzig) described a new method of staining the nerve-fibres in the central nervous system, and showed some excellent preparations. The method consists in staining the preparations in acid fuchsin (Fuchsin, S. 130 of the Berlin Aniline Manufacture), washing in a weak alcoholic potash solution, and then mounting in the ordinary way in Canada balsam. This method has great advantages above all other methods; it selects the nerve-fibres only, of which it stains portions of the medulla, while it leaves the axis cylinder free, and it picks out the smallest fibres, such as no other reagent, not even gold chloride, does. (As aniline staining forms now such an important part in all microscopic examinations, especially in the detection of micro-organisms, and as the different staining agents vary so very much in their properties, as sent into commerce by the different aniline manufacturers, it will interest many of your readers to know that those used by Weigert, Koch, and other German pathologists are best obtained from Dr. Gübler, 17, Dufour-strasse, Leipzig.)

Of other papers of pathological interest may be cited Dr. v. Mering's paper on the "Removal of Portions of the Cerebellum in Dogs." The removal of superficial parts of both the vermis and the hemispheres produced simply temporary stiffness of the muscles of the neck (in harmony with Hughlings-Jackson's view on the function of cerebellar cortex); the removal of the whole of the vermis only was followed by permanent symptoms, consisting chiefly of inco-ordination (in harmony with Nothnagel's views). Dr. Gudden read, in the Neurological Section, a paper on the "Course of the Optic Nerves." From a series of experiments on young animals (cats and rabbits) Gudden does not believe either in Munk's or Ferrier's cortical centre, but places the centre of vision in the corpora quadrigemina, and distinguishes three centres—one for vision, one for the dilatation of the pupil, and one for the contraction of the pupil. The series of experiments is, however, not yet concluded. The only other incident in the pathological section was a powerful speech by Professor Zünker, in which he warmly defended Dr. Koch against the treatment the latter recently received at the hands of Pasteur at Geneva. From the feeling which this speech elicited it is evident that the arbitrary behaviour of Pasteur will still further increase the coolness existing between French and German savants.

In the Section for Medicine I wish to notice a paper by Professor Quincke on the Dyspnoea produced by large doses of salicylate of sodium, a paper by Professor Ewald on the Presence of Chloride of Leucin in the Gastric Juice, and one by Dr. v. Mering on the Anæsthetic Action of Acetal. Large doses of dimethylacetal and diethylacetal seem all to this author's experiments to produce anæsthesia, and even death, without affecting the heart's action. Their action would thus differ materially from that of chloral. Given to healthy men, even very large doses of these compounds produce simply sleep of a few hours' duration.

In the Section for Children's Diseases several important topics were discussed, such as animal vaccination (which found many and strong advocates), the feeding of infants and the different substitutes for mother's milk, milk as a carrier of infection, and such like. A subject for discussion at the next annual meeting, which is to be held at Fribourg, was arranged for; and at the suggestion of Dr. Steffen and Professor Demme, the tuberculosis in children, especially in its etiological and pathological relations, was chosen.

Eisenach, Sept. 24th, 1882.

## Medical News.

**APOTHECARIES' HALL.**—The following gentleman passed the examination in the Science and Practice of Medicine, and received a certificate to practise, on Sept. 21st:—

Marmaduke Pittard, Guernsey.

The following gentleman also on the same day passed the Primary Professional Examination:—

George Birnie Hill, University College.

At the Preliminary Examination in Arts, held at the Hall on Sept. 21st and 22nd, 142 candidates presented themselves, of whom 95 were rejected, and the following 47 passed and received certificates of proficiency in General Education:—

FIRST CLASS.—Wm. Rickwood Baeot.

SECOND CLASS (in alphabetical order).—E. Barrett, C. W. Bellamy, R. A. Bramber, S. W. A. K. Broadway, G. Brown, F. A. Collington, T. A. B. Cooke, C. W. Crassweller, E. J. Cross, C. H. Dixon, E. A. Field, H. B. Garrett, G. T. Giddings, E. C. Greenway, W. J. Hoasmad, H. G. Henry, W. H. E. Howes, M. Imray, J. Angell James, R. B. Jeune, H. B. Knoblauch, T. H. Leggett, I. MacCarthy, H. F. Mantell, E. E. Morrall, P. L. Nettlehip, F. J. Nisbet, F. J. J. Orton, Frank Osborn, C. S. Pethick, T. E. P. Pollard, E. M. Quinby, A. F. Richards, W. H. Robinson, W. H. C. Roughhead, C. H. Sandbach, H. B. Shepherd, H. Archbold Smith, Percival Smith, Charles Wade, Chas. S. Watson, Chas. H. Wild, Evan Jas. Williams.

The following passed in Elementary Mechanics only:—

P. H. Daniell. | J. G. Johnson. | Ewen C. Stabb.

A BAZAAR held last week in aid of the funds of the Frome Cottage Hospital realised upwards of £100.

THE new small-pox hospital at Leeds is now ready for occupation. The cost of the building has been £2400.

THE Princess Beatrice has consented to become President of the new Shetland and Orkney Islands centre of the St. John Ambulance Association.

THE foundation stone of the new Sunderland and Durham County Institute for the Blind was recently laid in Sunderland by the Earl of Durham.

DR. ALLATINI, a Turkish physician, and distinguished for his philanthropic labours, principally in connexion with the establishment of schools, has just died.

THE yellow fever epidemic still rages in Texas and Florida. The mortality from the disease is not very great, but the anxiety and distress caused by it are considerable.

A FEVER hospital, with accommodation for twenty-four patients, is being erected at Maidstone. The buildings are to cost £3630. The site was purchased for £900, and another £800 is to be expended in enclosing it.

THE Local Board of Brentford has agreed to a sewerage scheme, the cost of which is to be £25,000. The sewage will be submitted to chemical treatment at Ealing, where works for the purpose will be erected.

THE concert given last week by Madame Adelina Patti in behalf of the funds of the Swansea Hospital was very successful, and will result in a large accession to the pecuniary means of the institution.

THE Library of the Royal College of Surgeons, which has been closed for a month for the necessary repairs, dusting, and cleaning, will reopen on Monday, Oct. 2nd. The Museum, not yet being finished, will be closed until further notice.

**ROYAL ALBERT ASYLUM, LANCASTER.**—The anniversary festival in connexion with this asylum for idiots and imbeciles was held on Wednesday at Preston. At noon the Rodgett Infirmary was formally opened at Lancaster, by the Earl of Lathom. The new infirmary is intended to accommodate those patients in the asylum who are suffering from infectious diseases. After the opening of the infirmary the party proceeded to Preston, where the annual meeting of the subscribers was held in the Town-hall. The Mayor of Preston presided. The annual report showed the institution to be in a very flourishing position. There are at present 482 patients, and the annual expenditure is £17,500. Last year the income was £19,778. There is accommodation for 120 additional inmates when the funds will warrant the expenditure, and a strong appeal was made for additional contributions. The results of the treatment in the institution are described as having proved most beneficial. After the general meeting a banquet was held in Preston Town-hall.

## PRIZES AT THE MEDICAL COLLEGES AND SCHOOLS.

THE following prizes and scholarships have been awarded for the Sessions 1881-82.

ST. BARTHOLOMEW'S.—Lawrence Scholarship and Gold Medal, R. J. Collyns; Brackenbury Medical Scholarship, C. A. Morton and T. W. Shore; Brackenbury Surgical Scholarship, R. J. Collyns; Senior Scholarship in Anatomy, Physiology, and Chemistry, E. C. Pettifer; Open Scholarships in Science, J. Elliott, E. C. Stocker; Preliminary Scientific Exhibition, H. W. Gardner and F. N. Brown; Jefferson Exhibition, E. O. Fountain; Kirke's Gold Medal, R. J. Collyns; Bentley Prize, R. J. Collyns, R. D. Batten; Hieben's Prize, C. B. Innes; Wix Prize, J. Robinson; Harvey Prize, H. C. Chapman; 2, J. Gay; 3, G. L. Wallis; 4, H. H. Fisher; 5, S. K. Allcock; 6, Wunderlich; 7, G. P. Newbolt; Practical Anatomy, Senior, Foster Prize, C. Heath; 2, S. H. Habershon; 3, F. E. Mathews; 4, E. Jessop; 5, H. C. Chapman; 6, O. R. Julian; 7, S. J. Palmer; 8, F. P. Maynard; 9, J. P. Roughton. Practical Anatomy, Junior, Treasurer's Prize, K. Humphry; 2, T. M. Wright; 3, R. H. Coombes; 4, T. W. Duff; 5, R. F. Towers; 6, L. P. Shadbol; 7, B. Farnwall; 8, J. Soutter; 9, H. W. Gardner; 10, H. D. Rolleston. Junior Scholarships, W. G. Spencer; 2, J. Gow; 3, H. D. Rolleston.

CHARING-CROSS.—(Summer Session, 1881, and Winter Session, 1881-82).—Llewellyn Scholarship: certificate and £25, C. F. Clarke. Golding Scholarship: certificate and £15, H. A. Sheppard. Governors' Clinical Gold Medal, E. Atkins. The Pereira prize: certificate and £5, A. E. Dodson. Senior Anatomy: silver medal, H. A. Sheppard. Junior Anatomy: bronze medal, E. T. Gregory. Physiology: silver medal, E. S. Barnett. Practical Physiology: silver medal, A. R. Jolliffe. Chemistry: silver medal, F. O. Shedman. Practical Chemistry: silver medal, G. Morgan. Senior Medicine: silver medal, G. H. Phillips. Junior Medicine: bronze medal, G. Morgan. Senior Surgery: silver medal, G. H. Phillips. Junior Surgery: bronze medal, G. Morgan. Botany: silver medal, R. Fletcher; Materia Medica: silver medal, G. Morgan. Midwifery: silver medal, G. H. Phillips. Forensic Medicine: certificate, E. Atkins and H. d'Arcy Power, (equal). Pathology: silver medal, G. H. Phillips.

GUY'S.—Open Scholarship in Arts: Albert Edward White. Open Scholarship in Science: John Wychemford Washbourn. The Treasurer's Gold Medal for Medicine: Lauriston Elgie Shaw. The Treasurer's Gold Medal for Surgery: John Alfred Parry Price. Beane's Prize for Pathology: John Alfred Parry Price. Michael Harris Prize for Anatomy: George Elliott Caldwell Anderson. Fourth-year Students: Louis Albert Dunn, first prize, £25; Thomas Carr, second prize, £10. Third-year Students: Edgar Ernest Masters, first prize, £25; Francis Barclay Willmer Phillips, second prize, £10. Second-year Students: George Elliott Caldwell Anderson, first prize, £25; Reginald Maurice Henry Randall, second prize, £10. First-year Students: John Wychemford Washbourn, first prize, £50; Sydney Wachter, second prize, £25.

KING'S COLLEGE.—Warneford Scholars: Ernest Paul Alphonse Mariette, Richard John Stephens, Cecil Danford Greenwood, Sambrooke Exhibitors: Philip Henry Hensley, Evan Lewis Hickey. Clothworkers' Exhibitioner: James Wheatley. Senior Medical Scholar: Walter Tyrrell Brooks. Second-year Scholar: John Power Gray. Junior Medical Scholars: Albert Carless, James Wheatley, Albert Lindow. Winter Session: Jeff Medal, John William Kealy; Warneford Endowment, Herbert Crowley Dent and John William Kealy, prizes; Leathe's Endowment, Obadiah Johnson, prize; Anatomy, Charles Harry East, prize; Physiology, Cornelius Clement Caleb and Robert Chambers Priestley, equal, prizes; Chemistry, John Freeland Freeland, prize; Medicine, Robert Garner Lynam, prize; Clinical Medicine, Robert Garner Lynam, prize; Surgery, Robert Garner Lynam, prize; Clinical Surgery (Professor Wood), Walter Tyrrell Brooks, prize; Clinical Surgery (Professor Lister), Bertram Herbert Stevens, prize; Comparative Anatomy and Zoology, Arthur Egerton Hensley, prize. Summer Session: The Todd Clinical Prize, Lewis Archer Buck; the Tanner Prize, Herbert Crichton M'Donnell; Obstetric Medicine, Charles Harry East, prize; Forensic Medicine, Nathaniel Henry Turner, prize; Materia Medica, Augustus Frederick Dimmock and George Wale, prizes; Practical Chemistry, Philip Percy Manning, prize; Botany, Arthur Egerton Hensley, prize; the Carter Prize for Botany, Albert Carless, gold medal and prize; Pathological Anatomy, Nathaniel Henry Turner, prize; Practical Physiology, Ernest Paul Alphonse Mariette, prize; Practical Biology, Arthur Egerton Hensley, prize.

LONDON.—Entrance Science Scholarship: £60 scholarships, F. J. Smith; £40 scholarship, not awarded. Buxton Scholarships: £30 scholarship, S. R. Hodge; £20 scholarship, J. W. Pugh. Letheby Prize for proficiency in Chemistry, £30, A. J. Richardson. Anatomy, Physiology, and Chemistry: £25 scholarship, given by the Medical Council, F. Hichens; Anatomy and Physiology, £20 scholarship given by the Medical Council, H. Cropley. Clinical Medicine: £20 scholarship, given jointly by the House Committee and the Medical Council, R. F. Fox. Clinical Surgery: £20 scholarship, given jointly by the House Committee and the Medical Council, R. F. Fox. Clinical Obstetrics: £20 scholarship, given jointly by the House Committee and the Medical Council, A. J. Richardson. Dressers' prizes for zeal, efficiency, and knowledge of Minor Surgery, given by the House Committee: £15 prizes, J. M. Evans and J. E. Crisp; £10 prizes, J. Thomas and F. Hichens; £5 prize, not awarded. Dissection prizes: H. Jabboor, jun., and H. Jabboor, sen. Osteology prizes, in lieu of £15 not awarded for Minor Surgery: J. Vincent and C. T. Samman.

MIDDLESEX.—Broderip Scholarships for the best examination at the Bedside and in the Post-mortem Room: First, A. E. Tate; second, George Frost. Governors' Prize, W. H. Crago; Exhibition in Anatomy, first year, Bernard Lawson; Medicine, W. H. Crago, H. J. Thornton; Surgery, W. H. Crago, H. J. Thornton; Pathological Anatomy, W. H. Crago, H. J. Thornton; Practical Surgery, C. L. Hudson; Anatomy, C. L. Hudson; Physiology, C. L. Hudson; Chemistry, T. H. Williams; Dissections, E. G. Foot; Midwifery, C. L. Hudson; Forensic Medicine, E. G. Foot, J. S. Robertson; Materia Medica, T. H. Williams; Practical Chemistry, R. Trood, T. H. Williams; Botany, T. H. Williams; Practical Physiology, E. B. Osmond; Comparative Anatomy, C. L. Hudson;

Psychological Medicine, C. L. Hudson; Medical Society's Prize, C. L. Hudson. Entrance Scholarships, Oct. 1881, first, A. B. Hinde; second, E. B. Osmond. Certificates of honour in order of merit: Surgery, R. S. Bowker, W. W. Linney; Pathology, P. W. Bassett-Smith, V. H. W. Wingrave; Practical Surgery, A. F. Stace, E. H. Freeland, B. F. Hartshorne, N. H. Forbes; Anatomy, A. F. Stace, E. Foot, J. K. Frost, E. H. Freeland, J. S. Robertson, N. H. Forbes; Physiology, A. F. Stace, J. S. Robertson, A. Y. Rely, E. H. Freeland; Chemistry, J. Petherbridge, C. J. Tabor, H. Baldwin; Midwifery, J. S. Robertson, A. Kirby, A. Y. Rely, E. G. Foot; Materia Medica, Ifor Davis, W. J. Spoor, C. J. Tabor, R. Trood, B. Lawson, A. B. Hinde; Practical Chemistry, Ifor Davis, G. S. Ware, C. J. Tabor, W. J. Spoor, A. E. Brackenbury, C. E. Thomas, B. Lawson, A. B. Hinde, E. Nicholson, R. Roberts; Botany, B. Lawson, R. Trood; Practical Physiology, M. Bates, S. Nicholson, F. M. Cealy, C. J. Tabor, G. S. Ware, E. L. Buckland, B. Lawson, A. Thomas; Comparative Anatomy, E. T. Collins; Psychological Medicine, H. G. Nicholson, A. W. Ogle, J. S. Robertson, E. H. Freeland, E. G. Foot; Dissection, C. L. Hudson, W. E. Newey; Prosectors, R. S. Bowker, W. H. Livermore; H. G. Nicholson, J. R. Roberts.

DURHAM, Newcastle-upon-Tyne.—Summer Session, 1891: Botany, medal and first certificate, William Jaques; Practical Chemistry, medal and first certificate, W. Jaques. Practical Physiology, medal and first certificate, W. H. Wigham; Materia Medica, medal and first certificate, William Jaques. Midwifery, medal and first certificate, not awarded. Medical Jurisprudence, medal and first certificate, A. Hepworth. Therapeutics, medal and first certificate, A. Hepworth. Pathology, medal and first certificate, Charles S. Blair.—Winter Session, 1891-92: Senior Anatomy, medal and first certificate, J. S. Revely. Junior Anatomy, medal and first certificate, F. Proud. Dissections, medal and first certificate, T. Clifford. Senior Physiology, medal and first certificate, not awarded. Junior Physiology, Medal and first certificate, A. Green. Medicine, medal and first certificate, S. Brookfield. Surgery, medal and first certificate, C. H. Milburn. Public Health, medal and first certificate, S. T. Fruen.

OWENS COLLEGE.—Turner Scholarship, £25, no competition. Dumbley Surgical Prize, £20, John M. Beverley and John S. Withers. Platt Physical Exhibitions, £15 each, second year, no competition; first year, Robert Briggs Wild, and prox. acc., William Gordon Little. Dauntsey Entrance Scholarship, £100, Robert Briggs Wild. Class prizes: Third year—Medicine, £5 5s., W. Thorburn; Midwifery and Diseases of Women and Children, £5 5s., R. Jennings and Ernest Septimus Reynolds, and prox. acc., Gilbert Lacy Barritt and John Hervey Jones; Pathology and Morbid Anatomy, £5 5s., Wm. Thorburn; Medical Jurisprudence, £3 3s., William Jones Black; Hygiene, £3 3s., Wm. Thorburn; Practical Surgery, £3 3s., John Hervey Jones; Ophthalmology, £3 3s., Wm. Thorburn. Second year—Anatomy, £5 5s., Alfred W. H. Walker and Richard Thomas Williamson; Physiology, £5 5s., Otto Jackson Kauffmann; Surgery, £5 5s., Otto Jackson Kauffmann; Materia Medica, £3 3s., Richard Thomas Williamson. First year—Anatomy, £5 5s., George Frederick William Braide; Physiology, £5 5s., Robert Briggs Wild; Practical Physiology, £3 3s., Brian Melland; Practical Chemistry, £3 3s., John William Talent; Botany, Lectures, John Beard; Practical Botany, James Edwin Thompson.

QUEEN'S COLLEGE, BIRMINGHAM.—Winter Session: Medicine, medal and first certificate, S. C. Lawrence. Surgery, medal and first certificate, J. H. North. Pathology, medal and first certificate, S. C. Lawrence. Physiology, medal and first certificate, C. E. Puralow and G. H. Nelson (equal). Practical Physiology, medal and first certificate, G. H. Nelson. Anatomy, medal and first certificate, C. E. Puralow. Junior Anatomy, medal and first certificate, W. B. Featherstone. Practical Anatomy, medal and first certificate, C. E. Puralow. Junior Practical Anatomy, medal and first certificate, W. F. Emery. Chemistry, medal and first certificate, W. Aston.—Summer Session: Midwifery, medal and first certificate, C. E. Oldacres. Forensic Medicine, medal and first certificate, E. D. Vinrace. Practical Chemistry, medal and first certificate, S. Barwise. Materia Medica, medal and first certificate, S. H. Harrison. Botany, medal and first certificate, W. B. Featherstone. (The Sands-Cox prize was not awarded.)

## Medical Appointments.

*Intimations for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning at the latest.*

ANDREWS, ARCHIBALD G., M.R.C.S., has been appointed a House-Physician at the London Hospital.

CASEY, PHILIP FORTH, L.R.C.S.I., L.K.Q.C.P.I., has been appointed Visiting Surgeon to Hay Gaol, N.S.W.

DESHON, FREDERICK PETER, M.R.C.S., L.S.A.Lond., has been appointed Medical Superintendent at the Beechworth Lunatic Asylum, Victoria.

DUNLOP, J. D., M.B. Edin., L.R.C.S.E., has been appointed Senior Medical Officer at the Adelaide Hospital, Australia.

FENTON, GEORGE, M.R.C.S., L.S.A.Lond., has been appointed Honorary Consulting Accoucher to the Western Dispensary, vice T. Chambers, M.D., F.R.C.P., resigned.

HENRY, THOMAS, L.R.C.P. Ed., L.R.C.S. Ed., has been appointed Medical Officer for the Pomeroy Dispensary District, co. Tyrone, vice R. Henry, resigned.

HODGSON, G. G., M.R.C.S., has been appointed Honorary Surgeon to the Bootle Borough Hospital, vice C. Swaby-Smith, M.R.C.S., resigned.

HORMAZDJI, ROBERT M., M.R.C.S., L.R.C.P., L.S.A.Lond., L.M., has been appointed Assistant-Surgeon to the Cape Copper Mining Company (Limited), at their Works at the Cape of Good Hope.

JOHNSON, THOMAS, L.F.P.S.Glas. & L.R.C.P.E., has been appointed Medical Officer to the No. 2 or Knottingley District of the Pontefract Union, vice E. Stone, resigned.

KNIGHT, CHARLES FRED., M.D., M.Ch. Q.U.I., has been appointed Physician to Mercer's Hospital, vice Duffey.

LEE, HENRY BOYNTON, F.R.C.P., late of the Leeds School of Medicine and Infirmary, has been appointed Demonstrator of Anatomy and Physiology at the Sheffield School of Medicine, vice Dr. White.

NEVE, ERNEST F., M.B. & C.M.B., M.R.C.S., has been appointed Resident Physician to Cowgate Dispensary, Edinburgh.

REDWOOD, THOS. HALL, M.D., C.M.Dur., L.R.C.P. Ed., M.R.C.S., has been reappointed Medical Officer of Health for the Rymney Urban Sanitary District.

SYMES, JAMES, L.R.C.P. Ed., L.R.C.S.I., has been reappointed Medical Officer of Health for the Briton Ferry Urban Sanitary District.

VIVIAN, GEORGE E., M.R.C.S., has been appointed Medical Officer for the Tollerton District of the Great Ouseburn Union.

WALLERS, WILLIAM, M.R.C.S., has been appointed House-Surgeon to the Blackburn and East Lancashire Infirmary, vice Firth, resigned.

WANKLYN, JAMES A., F.G.S., has been reappointed Public Analyst for the Borough of Buckingham.

WEBB, HUGH GEORGE, L.K.Q.C.P.I., L.R.C.S.I., has been appointed Medical Officer of Health for the Northleach Rural Sanitary District, vice the Poor-law District Medical Officers, whose appointments have expired.

WEISS, WILLOUGHBY, L.D.R.C.S.E., has been appointed Honorary Dental Surgeon to the Western General Dispensary, Marylebone-road, W.

WILLETT, GEORGE G. D., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer to the No. 2 District of the Bristol Union.

WINDLE, BERTRAM C. A., A.B., M.B., B.Ch., Dip. State Med. Univ. Dub., has been appointed Pathologist and Registrar to the General Hospital, Birmingham.

## Births, Marriages, and Deaths.

### BIRTHS.

BROWNRIGG.—On the 25th inst., at Hill House, Gravesend, the wife of T. Annesley Brownrigg, M.A., M.D., of a son.

DOUGLAS.—On the 26th inst., at Avenue House, Leamington, the wife of W. Douglas, M.D., of a son.

LEFTWICH.—On the 20th inst., at Newcross-road, the wife of Charles Harcourt Leftwich, Surgeon, of a son.

MANSON.—On the 13th inst., at Littlewood-park, Alford, Aberdeenshire, the wife of Dr. P. Manson, of a son.

### MARRIAGES.

BRANFOOT—OGG.—On the 16th ult., at Coonoor, Neilgherry Hills, Madras Presidency, Arthur Mudge Branfoot, Esq., M.B., Surgeon Indian Medical Department, to Alice Stewart, daughter of G. E. W. Ogg, Esq., M.B., Officiating Deputy Surgeon-General to Her Majesty's Forces, Secunderabad.

MEYERS—WOODLEY.—On the 21st inst., at the Parish Church, Lewisham, by the Rev. C. D. Farrar, Herbert Henry Meyers, M.R.C.S., L.R.C.P. Ed., of Battersea, to Jessie Amy, second daughter of John Woodley, of Forest-hill.

PHILLIPPS—ANDERSON.—On the 21st inst., at St. Bartholomew's Church, Sydenham, William Alfred Phillipps, M.D., L.R.C.P. Lond., of Faversham, Kent, eldest son of William Phillipps, Esq., of Plymouth, to Isabella Grace, eldest daughter of William Cuning Anderson, Esq., of Aberdeen House, Sydenham.

SAVILLE—BOOTH.—On the 21st inst., at St. Margaret's Church, Holyrood, Prestwich, Manchester, John George Saville, L.R.C.S., L.R.C.P. Radcliffe, Manchester, to Elizabeth, elder daughter of the late John Booth, Esq., of Radcliffe. No cards.

WILCOX—CROWLEY.—On the 23rd inst., at All Saints' Church, Shooter's-hill, Henry Wilcox, M.B., M.R.C.S., of Dorchester House, Herbert-road, Woolwich, to Edith Mary, eldest daughter of L. A. Crowley, Esq., of Cambridge House, St. John's, S.E.

### DEATHS.

BAIN.—On the 21st inst., at Fulham-park-gardens, London, James Bain, M.D., Surgeon-Major H.M. Bombay Army (retired), second son of the late John Bain, Esq., of Morriston, Lanarkshire, N.B.

BELL.—On the 20th inst., at Baby-place, Bath, Henry Bell, M.D., aged 85.

BIRD.—On the 21st inst., at Kirby House, Heaton Chapel, near Stockport, John Durham Bird, M.B., aged 44.

GREENLEES.—On the 10th ult., at Muskoka, Canada, Alexander Greenlees, M.B. Toronto, aged 39.

HOGG.—On the 21st inst., at Morar, Galloway, after a long period of illness, Francis Roberts Hogg, M.D., Surgeon-Major, eldest son of the late John Hogg, M.D., formerly of Truro, Cornwall, aged 44.

ROGERS.—On the 21st inst., at Seampur, Bedford, Charles James Rogers, Deputy Surgeon-General, Indian Medical Department, 1 his 60th year.

THOMPSON.—On the 22nd inst., William Thompson, M.D., F.R.C.S.I. of Lisburn, aged 76.

*N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

## Notes, Short Comments, and Answers to Correspondents.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.*

*Lectures, original articles, and reports should be written on one side only of the paper.*

*We cannot prescribe, or recommend practitioners.*

*Local papers containing reports or news-paragraphs should be marked.*

*All communications relating to the editorial business of the journal must be addressed "To the Editor."*

*Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."*

### A POETICAL VIEW OF DEATH FROM CONSUMPTION.

WE extract the following passage from a book, the "Life and Letters of Edgar Allan Poe," by John H. Ingram, published by Hogg. All biography, by the way, is a branch of study peculiarly proper to medical men, and not least so the biography of a man like Poe. Poe's constitution was intensely of the poetical cast, with strange, but not uncommon, relation to the abnormal and the morbid. His life and his death, his habits and his opinions, are all worthy of the attention of those who wish to understand man and the bounds of his mental range. Hearing of the death of a friend from consumption, he wrote:—"How could she die of consumption! But it is a path I have prayed to follow. I would wish all I love to perish of that gentle disease. How glorious! To depart in the heyday of the young blood, the heartfull of passion, the imagination all fire, amid the remembrance of happier days." Our object is not to criticise this romantic view of phthisis, which seems to us as false as can well be, but to record it.

*Beta.*—We think the charges mentioned are quite reasonable. We do not like to see separate charges for medicine; but this does not affect the reasonableness of the tariff as a whole.

### A DISAGREEABLE DUTY.

*To the Editor of THE LANCET.*

SIR,—I feel that on professional grounds the unpleasant duty of accompanying an injured person to a hospital should be well represented. A short time ago I took a serious case of accident to the London Hospital. There had been sudden and great loss of blood from an injury to the vessels of the upper part of the forearm, and the man had been insensible, with stertorous breathing, ten or fifteen minutes previous to my arrival. The only notice taken of my request for a chair was by the porter addressing himself to the patient with, "Ere, you can walk all right; catch hold of my arm." I insisted that the semi-unconscious man (whose brachial I still held under my fingers) should be provided with a chair. This was then procured, and he was wheeled into the surgery, where a nurse was ordered to attend on the patient. She approached with scissors, apparently to remove the compress I had applied, and proceeded to take the arm from me, to which I objected, and said I was a medical man, and wished the house-surgeon to take the case out of my hands. He was informed of this by the nurse, whom he ordered to apply an elastic bandage, and ostentatiously proceeded to examine a minor case. Eventually I gave my history of the injury without eliciting either a reply or a look from this official, who turned on his heel.

Now, although I am not one who expects to be treated with deference by a fellow professional, I certainly think that a house-surgeon, if he cannot practise absolute politeness in the consulting-room, should try to attain to the standard of courtesy which usually exists among medical men, and not treat with contempt an outside practitioner whose duty brings him within the precincts of the hospital.

I am, Sir, your obedient servant,  
Shoreditch, Sept. 19th, 1882.

ALFRED WISE, M.D.

### "CHRONIC URETHRAL INFLAMMATION."

*To the Editor of THE LANCET.*

SIR,—In reply to your correspondent, "Young Surgeon," may I suggest that he should satisfy himself as to the absence or presence of a gouty diathesis. If his examination leads him to suspect its possibility, I would suggest the trial of salicylate of lithia in ten-grain doses three times a day.

I am, Sir, yours faithfully,

Kineton, Warwick, Sept. 25th, 1882.

KENNETH W. MILLICAN.

### THE SAMARITAN MOVEMENT IN GERMANY.

THE question of affording instruction to members of the general public as to the first steps necessary to be taken in cases of accidents, &c., has excited a good deal of attention in German medical circles. Fairs have been expressed that the holding of certificates of competency would give those who have passed the examination an exaggerated idea of their medical skill. Dr. Esmarch, of Kiel, the promoter of the movement, has explained that it is not pretended to impart any instruction as to curative measures, but simply to diffuse information as to the steps which should be taken to prevent any aggravation of the injury pending the arrival of medical aid. The fact of the assistance of the Samaritans being in all cases gratuitous, tends, in his opinion, to remove any danger of the abuses which it has been feared might affect the value of the system.

### "MEDICAL OPPOSITION TO IMPROVED REMUNERATION TO MEDICAL MEN."

*To the Editor of THE LANCET.*

SIR,—As you have thought fit on the authority of an anonymous "correspondent" to make an attack upon me, I appeal to your sense of justice to allow me to reply. I assume that your "correspondent" was none other than Dr. Barnes himself, as no one but himself had any interest in the matter, and if he has not suppressed the fact you have, that he commenced the controversy by making a personal attack upon the guardians as a body and upon three of them individually by name. He says he wrote for the "benefit of the public" and also in "justice to himself." I replied in "justice to the guardians," which seems to have astonished you. The vice-chairman had pointed out that if the salary had not been increased Dr. Barnes had supplemented it pretty considerably by sending in a bill for "extras," almost equal in amount to the salary, and therefore the request for an increase was unanimously refused. I was not present myself on that day, being ill at home with erysipelas of the face, but had I been present I should have voted as my colleagues did. In my reply to Dr. Barnes's attack I pointed out that his extra charges in midwifery cases were unheard of, so far as I knew, and out of all proportion to those of the other district officers of the union.

He had recourse to instruments in about one case in five—i.e., in twenty-one out of ninety-nine; but I think one of these was a case of version and not of forceps, but it does not materially alter the percentage. I adduced statistics published by the Royal Maternity Charity, from which it appeared that out of 20,000 cases instruments were resorted to in only 501 cases, or about one in 400; from the Lying-in Charity of Guy's Hospital, where the proportion was one in 132, and from our Workhouse Infirmary, where 117 consecutive cases were delivered without any resort to instruments at all. In face of such facts as these I thought—and still think—that Dr. Barnes's charges were monstrously out of proportion to anything I had ever heard or read of.

You assert that there is nothing "more certain than that professional opinion is in favour of a more frequent use of instruments." I should esteem it a very great favour if you would give me your authority for so astounding a statement, inasmuch as all the teachers I have ever heard and all the books I have ever read—and they have not been few—have most emphatically protested against such a practice, and only to be had recourse to as a *dernier resort*. You also say that it is "greatly to be regretted that a medical guardian should raise such a question in the newspapers." I beg to say that I did not "raise" the question. It was "raised" by Dr. Barnes himself in the newspaper, and but for his attack upon the guardians my pen would have been silent. Your last sentence embodies a most extraordinary code of morality. You say that "most medical guardians, even if they approved of an adverse vote against a medical servant, would be thankful for a reasonable excuse for taking no part in the discussion." As it happens, not being present, I did not "take a part in the discussion." On the same grounds I suppose you would excuse a butcher, grocer, or baker, if such happened to be guardians, from not taking a part against a member of his fraternity. Are medical guardians more than others to sit silent or wink at any unusual charges made by their brethren? As you appear to have seen only one side of the correspondence, I send you the whole, not with any expectation that you will print it, still less read the whole of it, but I would draw your attention to the second paragraph of Dr. Barnes's letter, in which you will perceive that he flatly contradicts himself, admitting in one sentence what he had distinctly denied in the preceding one.

In conclusion, I would ask you if you think that "professional opinion," which you assert is in favour of the more "frequent use of instruments," would justify their use in one case in five, or, for the matter of that, one in fifty-five or a hundred and five? My own experience in a midwifery practice of considerable extent, extending over a period of close upon thirty years, in which I attended several thousand cases, enables me to say that they are really not urgently required oftener than about once in 600 or 700 cases.

I am, Sir, your faithful servant,

J. H. SHORTHOUSE.

Croydon, Sept. 26th, 1882.

\* \* We gladly insert Dr. Shorthouse's letter, which raises certain interesting points, the consideration of which, on account of the lateness of the arrival of the communication, we must reserve till next week.—ED. L.

## "A CASE FOR HELP."

THE following subscriptions, received through Dr. Stewart, in Mr. Gaffney's case (THE LANCET, Sept. 16th, p. 464) were announced to us too late last week for publication:—

Mr. W. H. Rix, Taunbridge Wells ..	£5	0	0
Mr. C. Coates, Bath ..	2	2	0
Dr. F. H. Alderson, Hammer-smith ..	1	1	0
Medicus, Surbiton ..	0	5	0

The following additional subscriptions have been received at THE LANCET Office on behalf of the above:—

Mr. Vacher ..	£2	2	0
Anonymous ..	2	0	0
Dr. de Havilland Hall ..	1	1	0

J. B.—It would serve the gentleman right to be made to pay the fee, and if our correspondent has been materially hindered in his movements or holiday by consideration for this engagement, he would do right to take him into court. If not, we should scarcely advise him to take the trouble to go legally into the matter with such a gentleman. It is surely unusual for a stranger to write and ask a medical man to see after a nurse for his wife. By our correspondent's perhaps too ready compliance with that instruction he certainly "greatly obliged" his correspondent, who proved very unworthy of the kindness.

## A SUGGESTIVE POST-MORTEM.

To the Editor of THE LANCET.

SIR,—I enclose you notes of a post-mortem made a few days ago at the coroner's request.

A young woman, aged twenty-seven, was found dead in her bedroom one morning, having retired in her usual health the previous night at 9 P.M. The brain and other internal organs had a healthy appearance, though the lungs were congested. The stomach contained about eight ounces of a brown-coloured fluid, smelling strongly of chloroform. On being filtered, this yielded half an ounce of pure chloroform, which settled to the bottom of the graduated measure in which it was contained. It answered to the different tests, passing the vapour through a red-hot glass tube, dissolving camphor, &c. The exact amount taken could not be ascertained, but four half-ounce vials labeled chloroform were found between the mattresses empty, and smelling strongly of that substance. I forward this as a matter of interest, so much chloroform unchanged and unabsorbed being found in the stomach twenty hours after it must have been taken: as she retired at 9 P.M., was found dead at 9 A.M. the next day, and the post-mortem was not made till 5 P.M. This case also shows the importance and probable benefit of using the stomach-pump promptly, if called to a similar case before life was extinct. Tanner gives a case where a gentleman swallowed two ounces of pure chloroform; the stomach-pump was used seven hours after, and the patient recovered. I am, Sir, yours faithfully,

Sept. 26th, 1882.

B.

Inquirer.—The name of Samuel Thompson Birchell, who in the local newspapers is described as a physician and surgeon, and who committed suicide at Spennymoor last week, does not appear either in the Medical Register or the Medical Directory.

A Young Practitioner.—Registration is necessary for either purpose.

## QUERY.

To the Editor of THE LANCET.

SIR,—Will you be so good as to inform me in your notices to correspondents in what book or books I should find an account of the Biology of Putrefaction and Allied Processes?

I am, Sir, yours truly,

Newark, Sept. 18th, 1882.

W. B. CLIFFORD.

\*. The question is a somewhat wide one, the subject being practically coextensive with that of the life history and properties of bacteria and the microscopic fungi and algae. The most recent researches are to be found mainly in various scientific journals and reviews, abstracts of which appear from time to time in our columns. For a general outline of our present knowledge our correspondent may consult especially Tyndall's "Floating Matter in the Air," Schutzenberger on "Fermentation," and Pasteur on "Wine." For more detailed and recent investigations, original papers in various foreign scientific and medical journals, such as *Comptes Rendus*, *Virochow's Archiv*, &c. The writings of Cohn, Pasteur, Billroth, Lister, Koch, Bastian, Wernich, and a host of others whose names might be mentioned. Very valuable information is contained in the "Mittheilungen aus dem Kaiserlichen Gesundheitsamte," Berlin, 1881.—ED. L.

## "SUDDEN DEATH THREE WEEKS AFTER DIPHTHERIA."

To the Editor of THE LANCET.

SIR,—Mr. Charlton, at page 515 of last week's LANCET, refers to a case of sudden death after diphtheria, requesting an explanation. A reference to my paper, section 819:6, will greatly aid him. Dr. Cumming's paper enters fully into the subject, and shows how paralysis of the cardiac branches of the vagus explains some cases.

I am, Sir, yours, &c.,

Boundary-road, N., Sept. 26th, 1882.

MEDICAL DIGEST.

## VENESECTION.

THE New York Medical Record states that Dr. Forjyce Barker advocates more frequent resort to this now nearly obsolete measure. "He is convinced that in certain cases it is essential to bleed the patient, and that life may be saved thereby." Surely this conviction has never been altogether absent from the minds of medical practitioners.

Mr. R. F. Woodcock.—The best hospital tents we are acquainted with are those manufactured by Messrs. Piggett Brothers, 66, Bishopsgate Without, E.C. They are provided with raised flooring, and with double walls and roofing. Good wooden tents can be procured from Messrs. Lascoll's, of Bunhill-row, E.C. Iron hospital buildings can be seen already erected on an open site in Victoria-street, S.W. As to the use of temporary hospital buildings, consult the recently issued Tenth Annual Report of the Medical Officer of the Local Government Board, pages 10 and 22.

M. G. E.—The practice is very objectionable.

## TREATMENT OF EPILEPSY.

To the Editor of THE LANCET.

SIR,—Would any of your correspondents kindly advise me, from their experience, as to the treatment most likely to be successful in a case of epilepsy in an adult (male, age twenty-five)? The patient in question has suffered from epilepsy for several years, and at the present time has attacks (petit mal) about once a week. Bromide of potassium in doses of twenty to forty grains has been taken by him daily for years, and latterly valerianate of zinc has been given in addition to the bromide, which he is now taking in about three-grain doses three times a day. After commencing the zinc there was an interval of five weeks without an attack, but since then, although the doses of the zinc have been increased gradually from one grain to two and three-quarters, the attacks recur about once a week. The diet has been throughout most carefully attended to, and the usual conditions which are considered essential to the proper treatment of cases of epilepsy have been thoroughly carried out. The mind is quite unaffected, but I am sorry to say the disease has shown itself in other members of the family, a brother and sister of my patient having both suffered from it, though they are now quite free from attacks.—I am, Sir, yours faithfully,

Sept. 26th, 1882.

ALPHA.

## THE D-TRAP.

To the Editor of THE LANCET.

SIR,—In your answer of last week to "Still an Old Subscriber," you have not noted what, to my mind, is the most objectionable feature of the D trap—viz., the impossibility of ascertaining the condition of the leaden tongue. Should it be injured by accident, or corroded by time, it may be absolutely useless as a trap, and yet present a perfect external appearance. The best trap yet invented is the simple syphon-bend—the quicker in the bend the better.

I enclose a sketch plan of the drainage system I am at present introducing into this asylum. It has been found efficient, economical, and well adapted to our special needs.—I am, Sir, yours obediently,

Murray Royal Asylum, Perth, A. R. URQUHART, M.D.,  
Sept. 1st, 1882. Physician Superintendent.

\*. We fully concur with Dr. Urquhart that the system of house-drainage as shown in the plan he sends us is thoroughly efficient. The essential points indicated are those embodied in the model by-laws of the Local Government Board as to house drainage.—ED. L.

Mr. Thomas Richardson.—The answer depends entirely on the nature of the diploma.

Pyrexia has not enclosed his card.

Melbourne had better write to the Secretary of the College.

## INFECTIOUS DISEASE HOSPITALS AND DIPHTHERIA.

To the Editor of THE LANCET.

SIR,—Our infectious hospital is open (three combined authorities), and the Board have decided to admit diphtheria. I am not aware of any infectious hospital admitting such disease, and shall feel obliged if you will give me your opinion before I protest.—I am, Sir, yours truly,

Sept. 20th, 1882. SANTAS.

\*. Diphtheria is essentially a disease to be dealt with by such rigid isolation as can alone be provided in hospitals such as the one referred to, and unless all the wards are occupied by other diseases, cases of diphtheria should on no account be excluded. In the report on infectious hospitals, recently issued by the medical officer of the Local Government Board, many instances will be found of the isolation of this disease in hospitals provided by sanitary authorities.—ED. L.

## USE OF APOMORPHIA.

To the Editor of THE LANCET.

SIR,—Can you or any of your readers give me any account of the use of apomorphia hypodermically? Is it applicable in such cases of alcoholic coma as one gets in police practice frequently where there is great difficulty in administering an emetic? If so, is one-tenth of a grain sufficient, and should it be repeated? I do not find anything about it in the text-books.

I am, Sir, yours truly,

Sept. 26th, 1882.

ME M.

## THE MORTALITY AT GRANADA.

ATTENTION has recently been called to the fact that Geneva is the most healthy city in Europe, the annual mortality being 17 per 1000. Granada has the reputation of being the most unhealthy, the death-rate being as high as 65 per 1000 according to a continental journal.

## POISONING BY EATING MUTTON.

To the Editor of THE LANCET.

SIR,—In Husband's Forensic Medicine a case is given of a boy being poisoned by eating mutton. As there seem to be very few records of this form of poisoning, I beg to bring the following case to your notice. A family of four persons, with a friend, partook of an apparently sound joint of mutton. The next day, Monday, the whole family suffered from slight diarrhoea. On the Tuesday the youngest daughter, aged twenty, presented all the symptoms of severe peritonitis: pain, persistent vomiting, and pyrexia. On this day the father was also seized with severe vomiting, the two other members of the family still suffering from diarrhoea. I was informed that the friend had also suffered from diarrhoea. The youngest daughter and the father continued to present symptoms until the following Monday, when, after the usual treatment for peritonitis, the symptoms gradually wore off, leaving both patients extremely weak. We often hear of butchers being prosecuted for selling bad meat, but it is not often that we see or hear the result of eating this meat. In the above case the illness was most distinctly traceable to its cause, although the symptoms did not come on until the day following, and the cause of the illness might possibly have been overlooked if the accident had not happened to a highly intelligent family. I remain, Sir, yours faithfully,

Putney, September 26th, 1882.

EDW. F. GRUN.

*Difficulty.*—The case is a hard one. It happens almost by the hundred yearly, and, in the absence of any special circumstances, should not hinder the registrar from accepting certificates.

*Dr. Elder.*—Yes.

## "HABITUAL DRUNKARDS."

To the Editor of THE LANCET.

SIR,—Under the above heading a suggestion appears in THE LANCET of September 16th by "M.D.," in which he proposes to deal with them by sending them for a voyage in a testotal ship, which strikes one as not at all a bad idea; but when he proceeds to recommend the establishment of a retreat in a small island, "one of the Channel or Scilly Islands," it scarcely holds out the same prospect of success.

I would remind "M.D." that the ex-King Cetewayo declared that he had no distilleries in his own country, but he found to his regret that a shop had been opened recently on the confines for the sale of intoxicants, and he feared it would be impossible for him to prevent them being sent to his country from without. It is also matter for the grave consideration of "M.D." whether, in dispensing with the guides during the wanderings of his patients, he may not have eventually to institute an efficient staff of coastguardsmen, also liquor proof, or he may possibly find to his discomfort that, although the much-dreaded public-house is avoided, he has unwittingly opened up a new field to the smuggler, and that his patients have very rapidly developed marvellously aquatic tastes.

I beg "M.D." will pardon me for throwing cold water on his philanthropic project.

Sept. 21st, 1882.

I remain, Sir, yours faithfully,

G. P.

X. M. will oblige by forwarding his name and address, not necessarily for publication.

*Dr. Stanley Murray's* paper is marked for insertion.

*Dr. Dearden (Church).*—Soon.

*Mr. C. S. D. Rabbitt.* It is against our rule.

## "TESTIS IN PERINEO."

To the Editor of THE LANCET.

SIR,—Allow me to place on record another instance of this rare malformation, described in your issue of Sept. 10th. The deformity was observed at birth, and the child is now eleven days old, well-nourished, and healthy-looking. The right half of the scrotum is normal, and contains the corresponding testicle; the left half is slightly smaller, or apparently so, and without testicle. On the left side of the perineum, near the inner edge of the thigh, and encroaching slightly by its upper part on the angle between the scrotum and thigh, is a soft swelling of the size of a marble, covered by normal skin, and containing the left testicle. The latter is movable, but cannot be placed in the scrotum or groin. The spermatic cord is traceable upwards.

I am, Sir, yours obediently,

Oldham, Sept. 21st, 1882.

R. BRYDEN HILL, M.D.

## SEWER GAS.

To the Editor of THE LANCET.

SIR,—As much attention is now being devoted to the generation of syphilitic diseases caused by the leakage of gases from the sewers, it is interesting to know that the South Metropolitan Gas Company have just had the ground opened in several places to see if any leakage arose from the joints of the pipes laid in 1879, and they have found them perfectly tight. The material used for this purpose was Spence's metal.

I am, Sir, your obedient servant,

Lombard-street, London, Sept. 21st, 1882.

J. W. BARTLETT.

## DAY NURSERIES.

In answer to a request for information on this subject, a correspondent desires to direct attention to the "Crèche Annual" (Morgan and Scott), by Mrs. Hilton, who founded and still superintends the largest crèche in England.

*R. Scot Skirving, M.B.*—In an early number.

*Mater.*—The Middlesex Hospital.

## DRAIN-PIPES: A QUERY.

To the Editor of THE LANCET.

SIR,—Perhaps some of your numerous readers may be able to offer a hint or two in explanation of the following phenomenon, which has struck me, and probably many others, as being somewhat remarkable, and not without interest in connexion with the effects exerted by drain-pipes on the contiguous soil and atmosphere. Three feet below the surface of the lawn in front of my residence, which is situated miles away from any town, run three earthenware drain-pipes. Two of them convey the sewage from the house and stables respectively to the intercepting sewer; the third is simply a conduit for carrying off storm water. The point to which I wish to direct attention, and as to the rationale of which I should be glad of a suggestion, is the fact that the course of these drains is distinctly marked by the increased luxuriance in the growth and the deeper tint of the grass immediately over them as compared with the surrounding turf. To what can this variation in the condition of the grass be attributed?

I am, Sir, your obedient servant,

September, 1882.

M.D.

## ODE TO CARBOLIC ACID.

To the Editor of THE LANCET.

SIR,—Impromptu lines on reading a telegram that the wounded in Egypt were treated antiseptically:—

Now war is o'er, and times are placid,  
We'll sing of thee, carbolic acid!  
Thou art the friend I would repair to  
For many ills that flesh is heir to.

Our fathers knew thee not, but tried  
Their remedies with guesses wide;  
None approached to thee at all, some  
Used, however, Friar's balsam.

I proved thee first in '67,  
The wounded bless'd thee as from Heaven;  
They landed thee in grateful terms,  
Yet knew no theory of germs.

Should dreaded fever now appear,  
And friends avoid the place with fear;  
With thee we'll dire contagion meet,  
Confining it with sprinkled sheet.

Against pyæmia, putrescent fever,  
We hold in thee a mighty lever;  
For sarcina and ailments peptic,  
All hail to thee, great antiseptic!

Barcelona, Sept. 21st, 1882.

W.

## SPURIOUS HERMAPHRODITISM.

To the Editor of THE LANCET.

SIR,—It may be of interest to state that I have at present under observation a very similar case of spurious hermaphroditism to that mentioned in your columns as being born at the British Lying-in Hospital last Monday, and that I hope to show the child at our next medical meeting here in November. The child is now five-months-old, and although I attended the mother in her confinement, my attention was not directed to the genitals till six weeks later. The description given by Dr. Fancourt Barnes answers in every way for my patient; but it is possible to pass a bent probe into what seems to be the meatus urinarius, and feel its tip in the perineum, thus suggesting there is a vagina behind the perineum. Can Dr. Barnes pass a probe in a similar manner? If so, the question of an operation laying open the occluded vagina seems natural.

I am, Sir, yours truly,

Canterbury, Sept. 23rd, 1882.

BRIAN RIGDEN.

## "EXTRAORDINARY SURGICAL OPERATION."

To the Editor of THE LANCET.

SIR,—With regard to an article recently published in your journal on the above subject, I beg to state that neither Dr. Hinds, Dr. Cullen, nor myself had, directly or indirectly, anything to do with the production you so justly censure. We were all considerably disgusted when, a week or so after its appearance, our attention was called to it. None of us are subscribers to the paper in which it was published. I have ascertained that the article in question was written by a very young apothecary's assistant and embryo medical student ignorantly, but with the best possible intention. I at once remonstrated with the editor on his having published the article without consulting me, but thought best to let the matter drop there.—I am, Sir, yours truly,

Fermanagh Club, Baniskillen,

Sept. 23rd, 1882.

BAPTIST GAMBLE.

*Chandos.*—The main question is a little delicate, and does not admit of an absolute answer. But the case seems to us one in which the ordinary rule could not be held to apply in permanency and to a second generation. The distance and other facts make it unreasonable. At a convenient opportunity it will be right to come to an understanding. The amount of fee is a question to be determined by a due and combined consideration of the custom of the neighbourhood, and the rule which regulates our correspondent's charges in regard to patients at similar distances and in similar circumstances, with perhaps a little difference in favour of the family in view of its medical relations.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. Miller, London; Mr. Richardson; Mr. F. Treves, London; Mr. Hawkins; Messrs. Talbot, Gloucester; Dr. Murray, Edinburgh; Mr. Barker, London; Dr. Drummond, Newcastle-on-Tyne; Dr. Gabbett, London; Dr. Neill, New Zealand; Dr. Shorthouse, London; Mr. Wingrave, London; Dr. Evtat, London; Mr. Molyneux; Dr. McVall, Glasgow; Mr. F. Churchill, London; Messrs. Evans, Sons, and Co.; Mr. Dolan, Halifax; Herr Gustav Fischer, Jena; Dr. C. S. W. Cobbold, Earlswood; Dr. Megarry, London; Mr. Rabbitt, London; Mr. Millican, Kington; Dr. G. A. Rogers, London; Mr. W. E. Williams, Dwyland; Dr. Barr, Glasgow; Mr. C. Bischof, London; Mr. Bartlett, London; Dr. West, London; Mr. Moore, Plymouth; Dr. R. B. Hill, Oldham; Mr. Fenton, London; Dr. Armstrong, Newcastle-on-Tyne; Brigade-Surgeon Oughton; Dr. Thomson; Mr. H. Weekes; Mr. R. Rawlinson, London; Dr. Watney, London; Mr. Bernard; Dr. Dearden, Church; Mr. Van Buren, Aylesbury; Mr. Gamble, Enniskillen; Mr. Skirving, Dublin; Mr. Stanley Murray, Richmond; Dr. C. J. Williams, London; Mr. Quinlan, Bombay; Mr. Wheeler, Wokingham; Mr. Hodgson, London; Mr. Grinling, Burton-on-Trent; Mr. Smith, Chipping Ogar; Dr. Nicoll, New-cross; Mr. Dreschfeld; Messrs. Krohne and Sese-mann; Dr. Jacob, Dublin; Dr. Collingridge; Mr. Marcus Beck, London; A Friend of the I.M.D.; Workhouse Medical Officer; S. W., Lancaster; Y. Z., Truro; Sanitas; Difficulty; B.; Alpha; Mater; Agathos; X. M.; S. J. C.; Trocar; D. S.; B. A. F.; Matron, Leicester; J. P.; F.R.O.P.; &c., &c.

LETTERS, each with enclosure, are also acknowledged from—Mr. Powell, Liverpool; Mr. Vacher, Birkenhead; Mr. Smith, Halifax; Mr. Lever, Stratford-on-Avon; Messrs. Harvey and Reynolds; Messrs. Smith and Sons, Norwich; Dr. Thompson; Mr. Graham, Malcolm; Mr. Palmer, Victoria-park; Messrs. Lee and Martin, Birmingham; Mr. W. ## SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year ..... £1 12 6 | Six Months ..... £0 12 6

TO CHINA AND INDIA ..... One Year, 1 12 10

TO THE COLONIES AND UNITED STATES ..... Ditto, 1 12 8

Post Office Orders should be addressed to JOHN CROFT, THE LANCET Office, 422, Strand, London, and made payable at the Post Office, Charing-cross.

Notices of Births, Marriages, and Deaths are charged five shillings.

Cheques to be crossed "London and Westminster Bank."

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on page 2, which not only affords ready means of finding any notice, but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Sons' Railway Bookstalls throughout the United Kingdom, and all other Advertising Agents.

Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher.

Agent for the Advertising Department in France—J. ASTIER, 67, Rue Caumartin, Paris.

# Introductory Address

DELIVERED AT

UNIVERSITY COLLEGE, LONDON,

*On the Opening of the Winter Session of 1882.*

By MARCUS BECK, M.S., F.R.C.S.

GENTLEMEN,—It having fallen to my lot to deliver the customary Address at the commencement of the present session, I have thought I could not better employ the time than in pointing out to you some of the theoretical principles upon which modern medical education is supposed to be conducted, and the reasons why the practice does not as yet, for all students, quite correspond with the theory.

Medical education, as we understand it now, is of comparatively recent origin. At the beginning of this century the profession was divided into distinct grades. There were, first, the physicians who had, as a rule, received such scientific education as was to be obtained at that time. They had mostly attended lectures at one of the English or Scotch Universities, and spent some time in practical study in a hospital. Then there were the surgeons, licensed by the College of Surgeons, then just founded in its present form. These also had received some education in anatomy and surgery. Lastly, there were the apothecaries, and to them fell the larger share of medical practice of the time. It was not uncommon, however, for these two last to be joined together in the person of one man, forming the surgeon-apothecary, who was the precursor of the modern general practitioner. The practice of the apothecaries differed from anything we have within the limits of the legitimate medical profession in the present day. They were essentially prescribing druggists, and could legally charge only for the medicine they prescribed. Thus they could receive no remuneration unless they ordered some medicine, and the more they ordered the more they got; a style of practice calculated to inspire a firm belief in the efficacy of drugs. It was not necessary for the apothecary to receive any medical education beyond being apprenticed to some one already in the trade, and the jurisdiction of the Society of Apothecaries, which necessitated even this amount of training, only extended to a distance of seven miles round London.

That the greater part of the practice of the country should have been in the hands of men like these seems to us now rather surprising; but we must not forget that even as late as the end of the last century science had not reached such a point of advancement as to make it a trustworthy guide to practice. The study of human anatomy was doubtless more advanced than other branches of medical knowledge, but even this was very far short of the perfection it has now reached. In chemistry oxygen had only been discovered for some twenty years, and the atomic theory had not as yet been established. The work of John Hunter and Billie had raised morbid anatomy to the rank of a science; but, from want of proper instruments, investigation into the finer processes of disease was almost impossible. In medical practice almost all the means of physical examination now in constant use, and without which we should feel it impossible in a great proportion of cases to make a diagnosis, were unknown. Auscultation, percussion, the use of the thermometer, the accurate chemical examination of the secretions, had yet to be invented, and the medical man had therefore little to do but to feel the pulse, look at the tongue, and listen to what the patient had to tell him. Surgery, being to a great extent dependent on anatomy, was, in some respects, more advanced than medicine; moreover, wounds and injuries require no special means of observation for their diagnosis.

At this time, therefore, science being of but little assistance, the apothecary was chiefly guided in his practice by empirical knowledge, handed down from generation to generation, and it was but natural that a long period of apprenticeship was considered the best means of acquiring such knowledge. The pupil was, as a rule, apprenticed at a very early age, and his term of service lasted seven years. His master during this time initiated him into

No. 3084

the art and mystery of healing, taught him to bleed and compound medicines; and from an early period it was his duty to attend to such patients as were willing to trust themselves to him. Being necessarily at first very ignorant, he thus learnt one thing, at any rate, to perfection, and that was the invaluable art of concealing his want of knowledge from the patient; and he probably learnt it much better than he would have done had he been troubled, as the young practitioner now is, with sufficient knowledge to raise in his mind any doubt as to whether he really knew what was the matter with the patient or not. Education by apprenticeship was, perhaps, fairly adapted to the knowledge of the time. It was useless for a student to spend years in the study of sciences which were not sufficiently advanced to be of any real practical service to him in his profession, and the mental training he would have derived from such a course of study would have been of but little use to him, when, from the insufficiency of the means of observation at his command, it could seldom have been possible for him to arrive at a conclusion as to the nature of a case by any logical process of reasoning. Perhaps his experience while an apprentice enabled him to jump to a conclusion as to what drug would best suit a given case as well as all the science of the time could have done. The instruction communicated to him by his master included a great deal that was true and useful, for much as science has done for us since that time, we are still as yet very far from being independent of traditional and empirical knowledge. The want of scientific training to instil a wholesome spirit of disbelief enabled the pupil to receive what his master taught him in faith, and to believe it with an earnestness rare in the present day. It was this that made him afterwards honestly believe that he knew a great deal in spite of what we should now consider his lamentable ignorance, and prevented his becoming the mere impostor that he is sometimes accused of having been. Under such a system of training it was, however, impossible for any but men of great original genius to break away from the trammels of tradition, and to take any part in the advancement of knowledge.

Yet the advance of medical knowledge at the beginning of this century was not without its influence on the lower branches of the profession, and many of the surgeon-apothecaries began to feel it a disgrace that so large a number of their branch of the profession had never received any proper medical training, and consequently a society was formed called the Association of Surgeon-Apothecaries of England and Wales, the object of which was in their own words "to improve the education of, and render more respectable, their own body." The effect of this agitation was the extension of the jurisdiction of the Society of Apothecaries to the whole of England and Wales, and after that no person was able to start in practice as an apothecary without having undergone a proper examination. From this time the old system of education gradually underwent a transformation. At first the period of apprenticeship was fixed at five years, the whole of which might be spent by the pupil in the service of his master. About ten years later it became the custom for every student to spend at least one year in a regular medical school. In 1826 this College, then called London University, was founded, and for the first time a systematic scientific education was given in London on essentially the same lines as are followed to the present day. Influenced by the example of this College, other schools quickly improved their arrangements for conducting the education of every student upon scientific principles. As the amount of scientific knowledge expected from the student increased, so it became necessary to prolong the time spent in the medical school at the expense of the period of apprenticeship. Twenty years ago it was the custom for the majority of students to spend one year, or sometimes two, as apprentices, and three years in the medical school. Now the change is almost complete, and it is rare for any student to be bound apprentice. The real cause which has been at the bottom of this change is that science has now so far advanced as to become an actual guide to practice, and consequently medicine and surgery can no longer be properly taught on the old empirical principles, but must be studied as sciences.

The change, however, from the old system to the new having been the result of a series of compromises, has succeeded in producing for the ordinary student a course of study which corresponds but imperfectly with the laws of scientific education. The amount of knowledge in every branch of medicine, and in each of the allied subjects, has

o

enormously increased, and every student now has to learn a great deal more than was expected from his predecessors of twenty years ago; while at the same time there is no reason to believe that the human intellect is increasing in capacity. How, therefore, to enable the student to acquire such a proportion of the increased sum of knowledge as to justify him in considering himself even decently educated has become a problem of no little difficulty. At present the examining boards require from the student a standard of knowledge which, unfortunately, many find it difficult to attain to; but it is not because it is too high that they cannot attain unto it. The standard has only been raised proportionally to the increase of knowledge, and the student will doubtless feel inclined to say with Solomon, "He that increaseth knowledge increaseth sorrow," for it is a serious fact that the proportion of students rejected at their examinations has correspondingly increased as the standard has been raised; and it is not now only the hopelessly lazy, or those who have some natural difficulty in acquiring knowledge who are rejected, but the industrious student of fair abilities sometimes meets with the same fate. Since in an evil hour the Royal College of Surgeons commenced the publication of the numbers passed and rejected from each school, it has become the custom in some places to submit the student to a test examination of equal severity to that of the College before signing the necessary schedule. By this means an apparent improvement has been obtained in the work of some schools, but it seems to me to matter but little to the student whether he is plucked by his teachers or by the examiners. This test examination, it is needless to say, has been devised for the benefit of the school and not of the student, ignoring the fact that the school is made for the student, not the student for the school. It has never been instituted in this College, and I hope it never will. The real effort to meet the higher standard must not be by such tricks as these, but by adopting the best possible course of training to enable the student to think well and correctly, and so more easily to acquire the necessary amount of knowledge; and in this we must be guided by the laws of scientific education. These laws are founded on certain principles now more or less generally recognised as true. The first of these is, that those manifestations of the functions of the brain which we call the mind are as capable of being improved in quality and order by training as are our muscular movements, and that just as those wonderful coördinated movements involved in playing a complicated musical instrument can only be acquired by commencing with the simpler exercises and gradually increasing their complexity and variety, so in training the mind the course of education must proceed from the simple to the more complex subjects. Thus, in a scientific education, the study of the exact sciences must precede that of the inexact. Another principle of equal importance is that in estimating the value of a given subject we must take into account its influence in mental training, as well as its direct practical utility in the business of life. The material with which the teacher has to deal no doubt varies greatly. There are some few happy individuals possessed of true genius who can acquire knowledge even under great disadvantages, and whose minds are by nature accurate and logical, and for these systems of education are of but little importance. Of this class, perhaps, John Hunter formed the most conspicuous example. With the vast majority, however, a correct mode of observation and thought is only acquired by proper training. A man of ordinary intelligence but devoid of mental training possesses a mind liable to lead him into error in many ways. He is unable to observe any but the simplest facts correctly, and supposing facts of any complexity are placed before him he is unable to draw correct conclusions from them. Should he attempt to generalise he is almost certain to fall into the error of drawing general conclusions from insufficient data, and premature generalisation is worse than none at all. In the history of medicine innumerable instances of this fallacy in reasoning are to be met with, but I am afraid we need not go back to history to find examples. From the want of sound generalisation to consolidate his knowledge, the learning of such a man is composed to a great extent of isolated facts, and, consequently, unless he is blessed with an exceptionally good memory, it must be somewhat limited in extent. Undue credulity, especially under the influence of educational or emotional bias, is another natural failing only to be corrected by proper mental training. The spirit of disbelief thus cultivated by scientific education is not perhaps an unmixed source of satisfaction, as it often leads us to

demand evidence and to find it wanting, when we would gladly for our peace of mind be allowed to exercise a little faith. In reading the works of many of the writers of the last century, it is difficult not to envy their simple faith in the useless drugs with which they drenched their patients. Perhaps nothing, however, marks the difference between the trained and untrained mind more than the instinctive way in which the former turns immediately from an effect to think of and search for its cause, and as our only hope of ever raising medicine to a true science lies in our fully understanding the causes of the various diseases we are called upon to treat, the value of this effect of proper mental training can hardly be overrated. Lastly, in any proper system of education some attention must be paid to classification, so that the knowledge acquired may be methodically arranged and immediately ready for use when wanted. In no branch of knowledge is a mental training more needed than in medicine. In no science are the facts to be observed more numerous or more difficult of observation; in none is the plurality of causes and the intermixture of effects more marked, and upon the correctness of the conclusions we draw from our observation, depends frequently the health or even the life of a fellow creature.

The practical application of these principles is perhaps best exemplified by the course of education prescribed by the University of London for its medical degrees. This has remained practically unchanged for twenty-two years, and the influence of its example on other examining bodies has been productive of great improvements in medical education. The essential feature of the system is that, before commencing medical study proper, the student shall receive a thorough training in the allied sciences. Each of the subjects comprised in the preliminary scientific examination is supposed to possess some special influence in cultivating a correct habit of thought and observation, in addition to its direct value in the practice of medicine. Chemistry and physics illustrate in their simplest form the mode of arriving at truth by observation and experiment; they show the precautions necessary to avoid error, the mode of arriving at general laws, and the dangers of premature generalisation. They impress upon the mind the necessary relations of cause and effect, dealing as they do to a great extent with conditions in which the causes are few and their effects clearly defined.

Botany and zoology teach the student the art of observing details accurately, and train the mind in methodical arrangement and classification of facts; and, as Bain says, "to learn to classify is in itself an education." Zoology and comparative anatomy also form an excellent introduction to, and give broader views of, human anatomy, and the study of the simpler structures and functions of plants prepares the student for the more complex subjects of human histology and physiology. The direct practical utility of these subjects varies considerably. Without some knowledge of physics and chemistry it is impossible for any man to study or practise medicine intelligently. Botany, including as it does the study of the lowest forms of vegetable life, which take so prominent a place in the pathological theories of the present day, has some direct influence on medical practice; but its value in other respects is not what it was, when "every green thing from the cedar to the hyssop" was supposed to possess some medicinal virtue, and when the apothecary in remote country places frequently gathered and prepared for himself the herbs that formed the chief part of his *materia medica*.

For zoology and comparative anatomy it is, I am afraid, almost impossible to claim any great practical utility. The exact knowledge of the anatomy and life history of the various parasites that infest the human body has done something to enable us to prevent their attacks, but even in this respect it is far behind botany. If any subject had to be omitted from this part of a medical education, zoology and comparative anatomy would probably be generally considered the one. As a training in observation and classification it is not superior to botany. To teach it properly a museum and dissecting room are necessary, while botany can be taught very sufficiently without any such means. The time required for botany is less than that for comparative anatomy; the dissection of a plant takes only a few minutes, that of the simplest animal can scarcely take less than one hour, and often many hours of patient labour. It is not likely, therefore, that zoology could ever be made a compulsory subject in an ordinary medical education, at the same time it would be a

most grievous error to exclude it from the subjects required for the higher qualifications.

A student who has been thus prepared by a short preliminary course of science, commences the study of the more special subjects of the medical curriculum with a mind trained to a proper habit of thought, and prepared to follow the inductive reasoning upon which medicine is founded. He is sufficiently trained in habits of observation to commence without difficulty the study of anatomy and histology, and his knowledge of chemistry and physics is sufficient to enable him to understand those parts of physiology to which these sciences are essential.

I need not follow further in detail the course of education according to this plan; the same system is followed to the end. The student does not commence to study the diseases of the body till he is familiar with its structure and functions in a state of health; and in studying disease he is encouraged to apply himself to medicine and surgery simultaneously, in order that he may learn that the same general principles apply to both, and that they are in fact merely branches of the same science. The fault of this system of education a few years ago was that it was too theoretical, and contained nothing in it to take the place of the practical instruction given so abundantly in the old system of apprenticeship. This has, however, of late years been corrected by the institution of practical classes and compulsory hospital appointments, and by teaching in the out-patients' room, until, at the present time, I am inclined to believe that the student gets quite as much practical instruction in every branch of his profession, except pharmacy, as he did under the old system.

Although the University of London, being unfettered by any previous system of education, was able thus to establish a scientific course of training according to the best theoretical principles, it has been otherwise with the corporations, and the consequence is that the education of the student whose object it is merely to obtain a licence is now conducted on principles which do not agree accurately either with the old empirical or the new scientific system, and consequently, he does not get the full advantage of either. The great majority of students in the present day begin medical study immediately after they leave school, having first passed one of the preliminary examinations conducted by one of the corporations or the College of Preceptors. This examination includes no science as a compulsory subject, except the rudiments of mathematics, which, although of course a useful training in methodical thought, is, as a purely deductive science, of comparatively little value as a preliminary training for medical study. A student, therefore, who has passed only the compulsory subjects, arrives at his medical school without any preliminary training in natural science. He finds then that he is expected to attend three classes during his first winter session—anatomy, physiology, and chemistry. One of the first things he will learn also is that, if he follows the course perhaps most commonly adopted, the first examination for which he will have to present himself is the primary at the College of Surgeons, and that this includes two subjects only—anatomy and physiology—and will not take place for two years. Upon these two subjects, therefore, he concentrates his attention, in but too many cases neglecting chemistry more or less completely; for I fear it may be said of but too many that the fear of examinations is the beginning of wisdom. In anatomy, with a mind totally untrained in accurate and minute observation, he begins by trying to learn the infinitude of details concerning the bones; and it is not to be wondered at if he finds it not only a difficult but a distasteful task. The study of descriptive anatomy, however, makes no demand upon any of the higher faculties of the mind, and, consequently, preliminary mental training is, as far as it is concerned, of comparatively little importance; and if the student will only give time and attention to it, he will almost certainly succeed in reaching the required standard of knowledge; although, perhaps, he will not master the subject as quickly and easily as if he had had some preliminary training in biological science.

Physiology being a subject full of fascination and interest, should naturally be very attractive to any student who takes real pleasure in his work; but, unfortunately, it consists in great part of the application of chemistry and physics to the study of life, and the ordinary student is at first ignorant of both these subjects; it is therefore impossible that he should gain more than a confused notion of what he tries to learn. From this point of view of mental training physiology,

valuable as it is in its proper place, is perhaps the very worst of all subjects with which to commence a scientific education. It is not an independent and self-contained subject, nor has it as yet acquired, or is ever likely to acquire, a place amongst the exact sciences; and it is a rule of scientific education that some training in the exact sciences should precede the study of the inexact.

(To be concluded.)

## Introductory Address

DELIVERED AT

### ST. THOMAS'S HOSPITAL,

On the Opening of the Winter Session, October 2nd, 1882.

By SEYMOUR J. SHARKEY, M.A., M.B. OXON.,  
ASSISTANT-PHYSICIAN, JOINT LECTURER ON PATHOLOGY, AND DEMONSTRATOR OF MORBID ANATOMY AT THE HOSPITAL.

GENTLEMEN,—When I was requested by my colleagues to deliver the Introductory Address at the opening of the Winter Session of 1882, I had no little trouble in arriving at a conclusion as to the most appropriate subject for the occasion. It did not appear to me that anyone occupying the position which I do to-day, and filling the office of teacher in one department only of medical science, was peculiarly fitted to advise students in detail as to the best method for them to pursue in all the branches of their future study. Far more valuable advice would come from each teacher in his own department. Nor did I think that the social and moral difficulties which students are likely to encounter in their career would be lightened most effectually by counsel given *ex cathedra*. Such subjects are better adapted for private conference among friends, as occasion may arise. Questions of great public interest, such as the anti-vaccination and anti-vivisection movements, would have afforded fitting topics for consideration, had they not already been so thoroughly threshed out and their absurdities exposed by men of far greater ability and holding far more prominent positions in the profession than I. But it did appear to me that an attempt to point out some of the most striking characteristics of modern medicine might be of service not only to those who are on the point of commencing their medical education, but to those also who have already accomplished a portion of it. For it must not be supposed that the science and practice of medicine at the present time, with all their imperfections, are such as they were in the student days of many a man now living; or that the knowledge in some subjects which the merest tyro now possesses was within the reach of even the greatest masters of our art so lately as half a century ago. No, medicine, like other sciences, though a plant of gradual growth, has passed through the greatest vicissitudes. From time to time it has burst into bloom, warmed by the glow of some enthusiastic genius, and then again it has languished almost to extinction under the withering influences of unscientific culture or neglect. Age after age passed away before it entered upon its present period of uninterrupted growth.

In the earliest times of which we have any record, when the priests were the repositories of all knowledge, real or pretended, medicine also, such as it was, formed a portion of their craft. The gods were supposed to be the originators of all good and evil among men, to reward them with health and to plague them with disease; and the priests were the intermediators. Left in their hands, the practice of medicine grew rank with ignorance, superstition, and imposture. So absurd a position did the art occupy in ancient times, that among the therapeutic agents quoted by a writer are "an hexameter from the 'Iliad' to allay the gout, and a verse of 'Lamentations' to cure the rheumatism."

The medicine of those early days was productive of but little which could materially assist in its future development, except the votive tablets which were hung by grateful patients in the temples of the deities, and which contained

a rough record of symptoms, and of the means adopted for their cure. But amid this utter darkness there appeared a man whose genius shed the dawning light of truth upon the science of medicine—a light which has ever been, and ever will be, the guiding star to new discoveries, but which for generations shone only with fitful gleams through the haze of ever-changing theories. Accurate observation of facts, and correct generalisations from them, form, as Hippocrates asserted, the only rational basis of medicine. And although this principle is so universally accepted at the present day that it may appear almost unnecessary to refer to it, still to discover it for the first time amid the mysteries and superstitions of early days required the keen penetration of a genius. Wherever in the history of medicine the Hippocratic method has been pursued, there true knowledge has increased; and where it has been laid aside and other methods substituted, stagnation or untruths have invariably prevailed.

But Hippocrates was too philosophical to reject all theory and to rely only upon the results of experience, as did the pure empirics. His guiding principle was a rational empiricism, which meant the results of experience accompanied by theories which rested on a basis of carefully observed facts. These tenets of the "father of medicine" must ever remain the keystone of all true advances in science. Theories have, however, often proved the will-o'-the-wisps of medicine, leading those who followed them into bogs and quagmires without end. But such delusive theories have not been those formed upon legitimate data, but mere products of the imagination, to suit which facts have been warped in the most ingenious ways. Founded upon a reasonable basis, they are the most potent aids in the advancement of knowledge. They lead to accurate observation, classification, and comparison of facts, and they open up fresh and fruitful paths of inquiry. In theories we embody our ideas of causation and of the links which bind phenomena together, and we challenge our fellow-workers to test their reliability by the constantly increasing weight of experience.

But even if the successors of Hippocrates had rigidly followed his scientific method, they must still have made but tardy advances in medicine. For the progress of science demands not only the application of proper methods, but their application in the right direction. How would chemistry have fared if only the compound substances had been studied and no attempt had been made to analyse them into their elements? And so long as anatomy was neglected, as it was in the time of Hippocrates, and medicine consisted merely in the study of the complex symptoms of disease, so long had our art to wait for any great development.

Accurate and admirable observations were accumulated on the natural history of many diseases and on some methods of treatment by able practical men; but medicine cannot be considered to have entered upon its career as a science until men's minds became keenly alive to the importance of the study of anatomy, and until the superstitions and restraints which prevented them from pursuing it were finally removed. Although human anatomy had been worked at now and again before the sixteenth century, it was not till then that it received that constant attention which has ever since been directed to it. The mere mention of such names as Fallopius, Vesalius, Sylvius, Eustachius, and many others, will touch a chord, I hope, not yet altogether lost to most of us, and will indicate the strides which must then have been made in that branch of knowledge which is the foundation of our science.

The next step in development was one which might naturally have been expected to follow close upon the study of structure, and that was the study of function, or physiology. We may almost consider the latter science to have had its brilliant commencement in the discovery by William Harvey of the most vital and all-pervading function of the economy—the circulation. But although the anatomy and physiology of the healthy body made considerable progress, their necessary application to the study of disease was by no means so quickly perceived. For a long time the grossest absurdities disgraced the practice of medicine. As an instance of them may be given the "Sympathetic Powder" of Sir Kenelm Digby, Kt., of Montpellier, which even in the sixteenth century had a great reputation. If anyone had received a dangerous wound this potent remedy was applied, not to the wound, but to the weapon which had inflicted it, and the weapon was dressed with ointment two

or three times a day. Sir Walter Scott thus refers to this practice in the "Lay of the Last Minstrel."

"She drew the splinter from the wound,  
And with a charm she stanch'd the blood;  
She bade the gash be cleansed and bound;  
No longer by his couch she stood:  
But she has ta'en the broken lance,  
And washed it from the clotted gore,  
And salv'd the splinter o'er and o'er.  
William of Deloraine, in trance,  
When'er she turned it round and round,  
Twisted as if she galled his wound.  
Then to her maidens she did say,  
That he should be whole man and sound."

Discovery followed discovery in anatomy and physiology owing to the interest in them which now prevailed, and the unflinching energy with which they were studied. Nor did the grosser changes of structure, which occur in the various organs in disease, elude the observers of those days. And when it was recognised that the specific functions of individual organs depended on their structure, and that both function and structure were altered in disease, the foundation of modern pathology and of the classification of diseases according to their anatomical characters was firmly laid. But the discovery, which of all others has contributed the most magnificent results to anatomy, physiology, and pathology, and which gave birth to modern histology, was the discovery of the cell by Schwann. For it was subsequently found that the ovum itself was a cell, and that all the organs and tissues of the body were formed by aggregations of these microscopical structures, which assumed a variety of shapes, and were the direct descendants of the original germ-cell. Here, then, one had suddenly discovered the anatomical unit of the organism. It was seen, too, that the physiological changes which constitute the functions of each organ must of necessity be due to the sum of the changes going on in the cellular units of which it is composed. And more than this, it was found that the gross naked-eye changes which are discoverable in the organs after death, and which are accompanied during life by the altered functions of disease, are attributable to certain definite changes in the structure of the individual cells. This gave rise to the cellular pathology of Virchow. Thus, owing to one simple discovery, the whole aspect of medical science was completely altered. Not only were the realms of physiology and pathology suddenly extended into the untrodden regions of the microscope, and the accurate descriptions of morbid processes which we now possess rendered possible; but it likewise became evident that the phenomena which occur in health and disease could no longer be considered as separate. The physiological changes characteristic of normal and the pathological changes which produced abnormal function occurred alike within the circumference of the cell, and the alterations were so gradual that there was no clearly defined limit between health and disease. Physiology and pathology must henceforth be one.

Meanwhile the sciences of chemistry and physics have made enormous strides, and have necessitated great modifications in our views of physiology. Their application under the terms vital chemistry and vital physics to the phenomena of living beings has rendered it probable that all physiological processes consist of physical and chemical changes which will have to be expressed in terms of these sciences.

And now, gentlemen, if I were asked what is the great characteristic of modern medicine, I should say that it consisted in the union of anatomy, physiology, chemistry, physics, and pathology to form the compound science of medicine, and in the clear appreciation of their necessary interdependence.

There was a time, and that not so long ago, when most of these subjects were thought to have but little to do with the actual practice of our art; when physiology and pathology were talked of rather as subjects to be mastered by a few learned professors, to be more or less familiar to a certain number of leading practitioners, and to be all but ignored by the great mass of the profession. But things are so no longer. A knowledge of disease can only be acquired after one has become familiar with the phenomena of health. Take as an instance the diseases of the spinal cord. It is only within the last few years that we have arrived at anything like precise knowledge of the affections of the central nervous system. But now a great variety of diseases are known, which affect certain definite regions, are accompanied by well-defined characteristic symptoms, last different periods of time, end some in recovery, some in death, some in a slowly but surely increasing incapacity. It would be quite

impossible for anyone to examine a series of patients affected with these diseases, to diagnose the nature and site of the lesion, to give the probabilities as to its course, and appropriate advice and treatment, unless he were familiar not only with the pathology, but also with the anatomy and physiology of the spinal cord.

Disease is not, as was once supposed, something quite apart from and having no connexion with the body in a state of health. It is simply a modification, at first slight, then perhaps increasing in the structural units of the healthy organism, accompanied by a temporary or permanent alteration of their function. And with this structure and function, both in health and in disease, it is necessary for the medical man to be acquainted.

But, it may be asked, is it a well-ascertained law that the brains of medical students increase in direct proportion to the increase of medical knowledge? My own personal experience would lead me to have the gravest doubts about the truth of this proposition. And if no such law exists, what limit is to be put to the demand for increasing knowledge at examinations? For it is beyond dispute that medical students are required now-a-days to cover a far larger field than formerly, and there is every probability that the field will grow still larger. This would not be so serious a question if the knowledge, however small, which becomes the permanent possession of the student, were really as sound as the trouble he has spent in acquiring it gives him a right to expect that it shall be. He may perhaps forgive those who control his education for the necessity they put him under of erecting temporary fortifications of unreal knowledge against the assaults of examiners. But he may be excused for complaining if, after he is safely through, his possessions prove as flimsy as his defences. And yet this is frequently the case. The student's energy has been spent in cramming the largest possible amount of information into his unwilling brain; and the latter hurriedly rejects it as soon as the pressure is removed. And what of the remnant that is left? It is too often a mass of undigested and disconnected facts.

Instead of constantly using his knowledge of anatomy and physiology to elucidate the phenomena of disease, the student enters upon his clinical studies as if he were commencing something entirely new, something upon which his previous training has but little bearing. The reason of this anomaly is, that throughout his career he is working at so high a pressure with a view to cover sufficient ground and accumulate the requisite number of facts, that he has no time to think quietly of the dependence of one part of his education upon the knowledge which he has acquired during another. In short, from the period at which students enter upon the practical clinical portion of their studies, they drop, in a large percentage of cases, their anatomy and physiology. It seems to me that the time will shortly come when an attempt must be made to rectify this error, and when the amount of detailed knowledge required at examinations must be lessened. Some method of selection of the more fixed and certain facts in science will have to be adopted, and the student will then have a chance of mastering these in a thoughtful and intelligent way; and, appreciating their importance in the practical work of his profession, he will have a wish to extend his scientific knowledge gradually in future years.

But to return from this digression to the immediate subject of the address—the characteristics of modern medicine. What has been the effect of the rapid progress of scientific knowledge on the actual practice of our art? The increasing accuracy of our knowledge of the normal tissues, and of the structure of the various organs into the composition of which they enter, has led to a more minute comparison of them in health and in disease. As a result of this, we have been able to differentiate with greater and greater clearness morbid conditions which are confined either to some tissues extending over considerable tracts of the body, or to some particular organ. Hence one of the most striking characteristics of modern medicine is the localisation of disease. Nor have we contented ourselves merely with post-mortem localisation of pathological changes, but unremitting efforts have been made to recognise their exact position during life. Hence the wonderful improvements which have been effected in the physical examination of patients. What a flood of light Laennec threw upon the obscure regions of the chest; so that diseases which we either had no conception of before his time, or which at any rate we were utterly incapable of detecting by the bedside, now

come within the grasp of physical examination. Invention after invention has followed. The ophthalmoscope, the laryngoscope, the thermometer, and a number of other instruments, by their application to the detection during life of conditions which had previously been observed only in the post-mortem room, or by the suggestions which they have offered for further pathological researches, have been of incalculable service to medicine.

The medical man now-a-days is expected to ascertain definitely in what organs of his patient disease is situated. Nor is it even thought a very satisfactory, or scientific, diagnosis to state broadly that a person is suffering from disease of the heart, lungs, kidneys, &c. He must explain what the nature of the morbid changes is, and what the position which they occupy; and being clear on this matter, he is more likely to be able to say what the cause of the malady is, and to predict its future course. This predicting the future course of disease, or prognosis, which depends partly upon an accurate diagnosis, partly upon an intimate knowledge of the natural history of disease, and partly upon a certain shrewd estimation of individual peculiarities and conditions, and of their probable modifying influence in each case, is one of the most searching tests of a man's ability and of that kind of skill which, except in rare instances, results only from ripe experience. To the public, who are our patients, it is evidently of vast importance, as it not only enables us to estimate within certain limits the longevity of our clients, but also to warn them against baneful influences, and to give them sound advice in many important domestic and social matters.

But however essential prognosis may be for the welfare of patients, the great test of the efficacy of our art naturally lies in the results of treatment. What can be said of this? Have improvements in the treatment of disease kept pace with the advances in pathology and in diagnosis? This is a question often asked and often answered most decidedly in the negative. It seems to me, however, that this is hardly a fair conclusion, and that it depends upon an erroneous view of the matter. For a long time in the history of medicine, treatment other than dietetic and hygienic consisted in giving drugs with a view to removing certain morbid symptoms, the results of diseases not then discovered; and as disease was looked upon as an entity superadded to the economy, it was natural to search for something which would counteract this hidden enemy. Consequently the chief anxiety was to discover so-called "specifics," and this went so far that the greatest activity was shown in searching for the "elixir vitæ," or something which would stave off even death. But as pathology advanced, and the diseases which caused the symptoms were found to be localised in certain organs and tissues, producing in a large number of instances their irreparable destruction or alteration, and very often a slow substitution of some morbid product in their place, it became evident that the hope of finding specifics for such affections must be chimerical. What specific, for instance, can we ever expect to find for granular kidney, for valvular disease of the heart, for degeneration of arteries, for advanced cirrhosis of the liver, and for many other conditions too numerous to mention? But the discovery that there can be no specific cures for such diseases is not a retrogression in medicine, but a most distinct advance, and has led to far more effectual methods of treatment than existed in former times. It may be convenient for the moment to divide diseases into—

1. Acute specific diseases, many of which follow a more or less definite course when left to themselves.
2. Acute and chronic non-specific diseases, which are accompanied by definite structural changes in organs.
3. So-called "functional" diseases, which produce much suffering, and indicate their presence by the most varied symptoms, but which do not depend on changes of structure, which reveal themselves to our present methods of investigation.

As regards the acute specific diseases, there is not at the present time, nor has there ever been, any method of curing them. Left to themselves, by far the greater number of patients recover; and this fact, together with their varying intensity in different individuals, as well as in different epidemics, has given ample opportunities to discoverers of supposed specifics. If these maladies depend upon the introduction into the body of certain poisons or lower organisms, there is no reason why antidotes may not some day be discovered. It seems more probable, however, from recent investigations, that our hopes must lie rather in some

method of vaccination as a preventive, than in the administration of drugs as antidotes. That we must not, however, despair of the latter possibility is shown by the effects of quinine in ague, and of salicylic acid in rheumatism. But even in our present comparatively helpless condition in the face of most of the acute diseases, the plan of simply dieting the patients, and placing them in favourable hygienic conditions, and only interfering with reluctance to relieve some distressing symptoms, or to counteract some disastrous complication, is far more effectual for good than the heroic bleedings and antiphlogistic treatment of former days.

For the second class of affections—those, namely, which consist of definite structural changes in organs,—we cannot expect to find specific remedies. It was only the ignorance that such morbid changes existed, and were the origin of the symptoms which presented themselves, that led men to harbour such groundless hopes. But are we in a worse condition now than we were then? Quite the contrary. Our present knowledge of physiology teaches us that health consists in a certain equilibrium, more or less stable in different individuals, which depends upon the regular, unobtrusive, and coördinated working of all our organs. The activity of the latter varies constantly within certain limits. The heart, for instance, beats more rapidly and energetically, and respirations are more frequent, during physical exertion than during repose. The kidneys act more vigorously in a cold atmosphere; the skin in a warm. If one of these organs is diseased, the guide to treatment is mainly a consideration of the physiological or healthy state, and our object in chronic affections should be to re-establish an equilibrium, as far as is possible, even though it be necessarily less stable than the normal one. Take, for example, a case of dropsy dependent upon an incompetence of the mitral valve. Here the slowing and obstruction in the circulation, and the consequent exudation of serum, are due to the heart's failure from the extra work thrown upon it and the wrong direction which is given to the blood. Now we know that in health the heart's work is diminished by a good many beats in the minute, and the circulation made easier, by assuming the recumbent position; we know too that digitalis is a drug which increases the force and regularity of the cardiac beat, and diminishes the number of pulsations, and consequently acts beneficially where the heart is beating rapidly, feebly, and irregularly. The patient is therefore ordered to bed and given digitalis. He loses his dropsy and appears to be cured. The physician, however, knows well that the disease remains as before, and that the extra work thrown upon the heart by the same amount of exercise which would be harmless to a healthy man, would again bring on dropsy in his patient. But the latter may often lead for a long time a comfortable existence, if he recognises the fact that his condition of health is less stable than it used to be, and if he acts upon the advice of his medical attendant. And so it is with a great many chronic diseases. We have no specifics which will cure them, but we have a knowledge of physiology and pathology which is far better than drugs, and which may enable our patients to live more at ease, though on a lower level of health, so to say, than they could possibly do if we substituted drugs for physiological rules of life. The two should be combined, but less prominence must be given than of old to the contents of the Pharmacopœia. We have then, it seems to me, made great strides in the treatment of chronic diseases in modern times, though our methods do not always appeal to the feelings of the public in the same way as if we dosed them with medicines.

In the third category of diseases referred to above—viz., those which are accompanied by no tangible structural alterations—physiological rules of life, especially as regards dietetics and hygiene, are still more efficacious than in the class of maladies we have just been considering; and we can often do much by drugs and other means as well.

(To be concluded.)

ON the 28th ult. the Rodgett Infirmary, in connexion with the Royal Albert Asylum at Lancaster, was opened by Lord Lathom, and was accepted by the Earl of Bective on behalf of the central committee. The building, which has been erected in the grounds of the institution, at a cost of £4000, is the gift of Mr. Edward Rodgett, of Darwen's Bank, Preston. Mrs. Rodgett furnished one half of the building.

## THE CUTANEOUS DISEASES OF CHILDREN.<sup>1</sup>

By DR. ROBERT J. LEE, F.R.C.P.

IN looking over the records of cases of cutaneous disease in children which have come under my observation during the past ten years, it seemed possible to analyse and condense them into such a form as to make the results of interest and value to the members of this Society. The total number I have seen of such cases in the course of each year has been on the average two hundred, sometimes more and sometimes less. I doubt so much whether we should gain any very practical knowledge from a statistical analysis of them that I have determined to present only very general conclusions of this kind to consideration, and to reserve a full statement for another occasion. For a somewhat similar reason it appeared to me well not to dwell on those rarer forms of disease which from time to time have come under notice, for I have seldom found that what are termed "unique cases" in this class of disease leave much matter for thought or prompt to new inquiry. They stand alone like curious specimens in a museum, peculiar and attractive on account of their rarity. Perhaps one of the most interesting subjects which can engage attention in the study of the diseases of children in all their forms is the extent to which age and age alone appears to exert an influence in determining the characters of morbid action, that is to say, in producing a distinct difference between typical characters as they appear in early and adult life.

The questions, then, which we may endeavour to answer are these: In what respects do the usual forms of cutaneous disease present peculiar characters in infants and children? The second question: In what ratio do certain forms occur more or less frequently in children than in adults? The third: What explanation can reasonably be offered for these differences? And fourthly: In what way must our treatment be altered to suit them? Now, there are certain forms of cutaneous disease peculiar to children. There is one form extremely common, but it is not a very definite one. It is that which we see so frequently affecting the head, forehead, and face of infants, the back of the ears, and generally the tissues of the head, face, and neck. We must not attempt to name it by any of the ordinary names, for this reason, that its characters are too general to answer to the accurate definitions of dermatology. It shows a feeble apprehension of the true spirit in which we should regard the subject of skin diseases to try to find a name for every case we see. It is difficult, I know, to liberate our minds from the force of habit, at the same time we must not fancy that to find a name and a place for a disease is really of much importance towards the scientific knowledge of its nature and treatment. We may take a single term to include all the varieties of this common disorder of the skin—the term dermatitis; that is a term analogous to those we use in the case of inflammation of other organs and parts of the body, as, for example, bronchitis, peritonitis, &c. Dermatitis of the head, the face, and the body is the commonest cutaneous disease of children. In the year 1879, in a total of all forms of skin disease in my hospital practice, of 197 there were 129 cases of dermatitis of the kind referred to. Last year, in a total of 200 cases, there were also 129 cases of dermatitis, or rather more than 63 per cent.; and so in other years I find much the same ratio obtaining. Dermatitis of the scalp in the child includes eczema and impetigo in all their forms and combinations. We may define any particular case if we please by some pathological addition—such as serous or purulent, scaly or epithelial, tubercular, and so on. No one can object to this, because it is an accurate mode of description. It is clear that the cutaneous diseases of children do not resemble those of adults in regard to the 63 per cent. of cases of ordinary dermatitis. If, however, we analyse the 37 per cent. remaining, we find that these include forms more or less common to all periods of life.

It may be urged that this dermatitis occurs in grown-up persons; at least that we cannot tell the difference between it in children and adults. This is not the case, whatever may be said to the contrary. Adults are not liable to the same tendency to inflammation of the scalp and neighbouring parts as young children. In the ordinary practice of a

<sup>1</sup> Read at the Medical Society of London, Nov. 17th, 1881.

hospital for children, more than 10 per cent. of the total number of cases are suffering from some form of cutaneous disease. This alone shows how commonly the skin is affected in early life. It is clear, then, that one of the first points to which attention would naturally be directed is the causes of dermatitis—its nature, course, and treatment. The 37 per cent. of other cases would be found to contain examples of *tinea tonsurans*, herpes in different parts of the body, congenital diseases of the skin—which, by-the-by, have a singular relation to the condition of maternal health during pregnancy,—a large number of cases of syphilis, a few of scabies, of scrofulous or tubercular disease, and some very rare forms which I shall purposely exclude. Lately the relation of dermatitis to vaccination has been receiving some attention.

A few years ago I ventured to suggest what appeared to be the probable connexion between vaccination and the skin disease which so often follows it. Dermatitis of the head or face may follow any local sore, whether on the head, face, or any other part. I mean to say we may take it as a fact that if the skin of a young child is inflamed at any point—as, for example, by the application of caustic in the treatment of *nævus*, by an injury or fall, but most commonly by vaccination—if the skin at that point and around becomes inflamed, from want of care, cleanliness, or other cause, then some other part, generally the head and face, may become affected. The same thing happens often after chicken-pox, herpes, measles, and some other maladies.

Now, I could well occupy an hour in discussing the question what is the connexion between the first local sore and the secondary disorder. It would not be right to infer that every case of dermatitis must have arisen from a local cause, at least there is no evidence that such is the case, but it is quite true that when a woman asserts that the skin complaint followed vaccination we are wrong if we deny the connexion. The question of difficulty to decide is this, Does the dermatitis of the scalp or face arise from a nervous irritation of the skin, or is it due to the absorption of some morbid material developed in the primary seat of inflammation, and arrested in the tissues of the skin, which are affected much in the same way that joints are affected in gout or pyæmia? I am quite certain that the dermatitis is not due in these cases to an external cause—that is to say, not to infection by contact, not to the transference of matter from the local sore to the head or face. Lately Mr. Hutchinson has given some attention to this subject, but I do not feel satisfied with the explanation he offers. He is speaking of dermatitis when it follows varicella, variola, or any exanthem as measles, "which," he says, "possesses the power in exceptional cases of making the skin irritable, and thus laying the foundation for long-continued and most troublesome conditions of prurigo." You perceive that we want either a physiological or a pathological explanation, which is not provided by saying that the skin is made irritable unless the reason for such irritation be given. I am inclined, after most careful consideration, to the view that dermatitis, when secondary, is due to absorption of some product of inflammation as yet unknown. I would even go further than this, and express the belief that all cases of dermatitis are due to a similar cause—that is to say, that strophulus, ecthyma, eczema, and impetigo, all occurring in the same child, as they do, in different parts of the body, are due to the presence of particles in the blood which excite cutaneous inflammation. I advance this view very much for the sake of discussion, though I may say it is the result of the observation of many hundred cases and careful thought. It has certainly had the effect of making the study of cutaneous diseases more interesting than otherwise they would be; and not only this, but it has led to very satisfactory results in the best test of its value—that is, in the practical treatment of this important class of disease in children.

Let me say here that the subject of cutaneous diseases had a great interest for me when in Paris, fifteen years ago, from the fact that it was the opinion of Professor Hardy, the distinguished dermatologist and physician, that English physicians were in darkness as to skin diseases. I certainly formed the impression, when acquainted with Professor Hardy's views, and the scientific method which he pursued in his observations, that he was not far wrong. He makes, however, the statement in his published lecture that eczema, psoriasis and others of the same class, are diathetic, much as gout, rheumatism, and some other diseases are hereditary, or at least to some extent dependent on hereditary influences. So far as children are concerned this statement is not

correct, though it is a curious fact that a certain number of children, not many, have dermatitis in a somewhat different form when there is hereditary tendency—that is to say, in about 2 per cent. of cases of dermatitis of the head and face, the disease is more obstinate, more irritable, and more severe; and then we find there is a history of family tendency to cutaneous disease. It is not necessary to point out the practical use of this knowledge in the treatment of such cases beyond saying that to these the ordinary rules of treatment of eczema and others of the class may be applied, whereas in ordinary dermatitis no such treatment is required. Dermatitis in its common form in children is not the eczema of dermatologists, nor impetigo, nor any offspring of theirs, but a simple inflammation of the skin of a more or less transitory nature, variety of degree, and frequently of uncertain origin.

It will be asked, Are we to regard strophulus, ecthyma, eczema, and impetigo, the four common names given to dermatitis in its various forms, as due generally to a local cause where a morbid product has been absorbed—that is to say, for example, whether in the process of dentition, in derangement of the digestive organs, as well as in some spot in the skin itself, are we to look for the local origin of the dermatitis which so frequently affects children? I would ask that this view may be considered impartially, and tested by past and future experience. It may be proper to be prepared with some reason for the fact that adults do not suffer in the same way as children in respect to the frequency with which the skin is affected. This is a difficult question, and may be submitted to dermatologists for an explanation. It is sufficient for me to observe simply the frequent connexion between dermatitis and some previous disturbance of the system of a young child, and so to look beyond the local treatment of the skin, although that is of the utmost importance, and endeavour to ascertain the primary cause of the dermatitis. This view indicates a very different system of treatment of dermatitis in young children from that which is required for the eczema of adults.

Let me now make a few remarks on the 37 per cent. of cases I have mentioned. We might take every form of cutaneous disease, and we should find that in the child or infant it is somewhat different from what we see in adults. For example, this is observed of herpes zoster, which occurs in from 3 to 3½ per cent. of all cases of cutaneous disease in children. Herpes does not so frequently affect the abdomino-dorsal region in children as in adults. We meet with it in relation with most of the important nerves of the face, head, trunk, and the humeral and femoral regions. Herpes is not so serious an affection in children, and often produces a little, if any, constitutional disturbance, or apparently much local pain. It has occurred to me to think that sometimes herpes is suppressed, and certainly I have seen instances where the vesicles were apparently arrested, and only faint indications seen of a change in the skin where the pain was located. Probably the same thing has been observed in adults, though I do not recall any special notice of it. During the five years from 1875 to 1880 inclusive thirty-three cases of herpes passed under my observation in hospital practice, of which only six were cases of herpes zoster—that is to say, were abdomino-dorsal in the seat of eruption. In the other cases, the face, forehead, arm, coccyx, or thigh was the part affected. We hardly find an explanation of this liability to herpes occurring in various parts in the supposition that the nervous system of young children is more sensitive than that of adults; and as I see no satisfactory reason for this difference, it will be better not to hazard any theories upon it.

The syphilitic cutaneous cases occur in the ratio of about 5 per cent. of all cutaneous cases, and the chief point of interest seems to me to be the relation which exists between the particular form of eruption and the history of the case. By proper management, I was enabled to obtain from both parents in many cases a succinct account of their history previous and subsequent to marriage, and thus to determine how far the condition of the child depended upon that of the parents. For instance, the form of eruption on the child, when marriage had occurred within twelve months of infection in the father, was very different from that where two or more years had elapsed between infection and marriage. I am speaking now, of course, of the first child. Within certain limits it seems possible to predict from the state of the child what was the history of the parents. That, at least, is the impression produced on my mind by the careful study of this subject, and after having

obtained the history of more than twenty families, the number of whose children born dead and alive was above sixty. Very many interesting and important details I am obliged to refrain from mentioning on this occasion, in regard to the subject of family syphilis, as they do not bear directly on the subject of the cutaneous diseases of children. At one time this subject seemed a hopeless one, for syphilis is not like variola, scarlatina, and that class of maladies, so that analogy rather misleads than assists. To take an example: The second child is brought for treatment; its age is between two months and six months. The first child, we are told, died soon after birth, and had symptoms of well-marked syphilis. In the second child we notice that the surface and deeper tissues of the skin are affected, the nasal and oral orifices are cracked, the skin of the nates is sore or ulcerated, and we are inclined to dismiss the case without a question. Compare this with a case of condyloma in a child over twelve months old; or one of softened gummata which have become furuncles, bluish, painless, soft boils, generally on the thighs or buttocks, and full of thick creamy pus. The family history of these two cases will be quite different. In the first the infection of the father is almost certain to be recent, and the mother will have suffered. In the latter, years will probably have elapsed since the father's infection, and the mother will be free from any trace of disease. These are typical cases. Between these cases, however, such varieties are met with as to make artificial classification of but little assistance in the study of this class of disease. The treatment of syphilitic dermatitis, as I have been accustomed to call the common form of infantile syphilis first described, as well as of the softened gummata and furuncles, is so simple and well known that it requires no remark.

Of the cases which remain there were about 6 per cent. of tinea tonsurans; sixty-four of these, which occurred during the years 1875 to 1880, were treated on the principles advanced in a short communication to the *British Medical Journal* (1877, p. 74). The principle rested on the ordinary laws which preside over the development of spores like the trichophyton, which may be destroyed by many agents when fully developed, but in the early stage resist their action. Further, that the value of the agents employed depends on their specific action as germicides, and not on their irritant properties, which inflame the cutaneous tissues. So that the method and frequency of application are the chief points to attend to, particularly in hospital practice, where cases are seen only once a week. The cases now remaining of any interest are too few to be considered in classes, and on account of their special peculiarity of character need not be referred to at the present time.

## SEVERE INJURY TO PELVIS AND RIGHT KIDNEY, AND SUPRA-RENAL CAPSULE.

By HARRY LUPTON, L.R.C.P. LOND., &c.,  
SURGEON TO THE STRATFORD-ON-AVON INFIRMARY.

THOMAS W—, aged sixty-nine, was admitted into the Stratford-on-Avon Infirmary on the 4th of August last, about 6 P.M. He stated that when in charge of a timber waggon, loaded to some three tons, he was overtaken by the front wheel which caught his boot, threw him down on his back, and passing between his legs went over his pelvis, and passed over his body above the left ilium. The accident had occurred some three hours prior to admission, about five miles out of town.

On admission he was suffering severely from shock; pulse was small and weak, extremities cold, and he was bathed in a cold sweat. Chief pain referred to ramus of left pubic bone. He was put to bed, hot bottles applied to the feet, and hot blankets to the abdomen. A little brandy and milk was given him, which was shortly rejected, together with some fragments of bacon and blood-stained fluid. The sickness persisted till about 5 A.M. on the 5th. The vomit consisted of dark bloody fluid, in quantities of a tablespoonful or so each time. The patient stated that he had passed urine about an hour before the accident. He had had no desire to pass urine since. An attempt to pass a catheter failed, the instrument being palpably deflected to the left on reaching the membranous portion. No history of prior

stricture or urinary trouble. Ordered small pieces of ice to suck. At 8.30 P.M. my colleague, Mr. Nason (senior surgeon to the infirmary), kindly saw him in consultation with me. There had been no effort or desire to pass urine. An endeavour to pass a catheter was made both by Mr. Nason and myself, with a similar result to the former attempt. The instrument passed no farther than the membranous portion, when it was palpably deflected to the left. To continue treatment with small quantities of brandy and milk and beef-tea. The patient had rallied considerably since admission.

On the 5th he was seen again at 10 A.M. by Dr. Kingsley (physician to the infirmary), Mr. Nason, and myself. Condition much the same; no attempt or desire to pass urine; no evidence of distended bladder or of extravasation of urine; but considerable distension of scrotum from effused blood, evidently the result of the bruising. At 3 P.M. seen again by Dr. Kingsley and myself. Some increase of scrotal effusion; no evidence of distended bladder. With the concurrence of Dr. Kingsley I aspirated above the arch of the pubic area of dulness limited to some two inches above this bone; no result. At 8.30 P.M. again visited by Dr. Kingsley, Mr. Nason, and myself. Symptoms, area of dulness, &c., unchanged. Scrotal swelling increased; but evidently no urinary infiltration. Total absence of red, brawny, inflammatory swelling, &c. Query—Had he total suppression of urine? But the characteristic symptoms of this grave condition were wanting. No odour of breath; no coma, &c.

No alteration of symptoms took place till August 6th, at 8.30 P.M., when the scrotal swelling having much increased, it was punctured in a number of places with a flat double-edged needle. A considerable amount of blood-stained serum drained from these punctures, but which was markedly free from the slightest urinary odour; though there was no increase of supra-pubic dulness. It was considered advisable to again aspirate down the pubes, as it was now some eight-and-forty hours since any urine had been voided, and all attempts to pass any instrument into the bladder failed as formerly. A small quantity of blood-stained serum was obtained as the needle passed into the subcutaneous cellular tissue, and again from the abdominal cavity, but this fluid was also markedly free from any odour of urine. General condition worse; pulse small, rapid, and weak; skin cold; temperature slightly below normal; perfectly conscious; no urinary odour of breath; no coma; no abdominal tenderness or evidence of peritonitis manifested all through, but hiccup at intervals since 6.30 P.M.

On Aug. 7th, about 3.30 A.M., sickness recommenced, and at 5 A.M. he died.

I had omitted to state that faeces passed involuntarily and without the patient's knowledge on the 4th, 5th, and 6th. Examination per rectum merely revealed the fact that there was no distended bladder beyond the prostate. It was thought by Mr. Nason and myself that the pubic arch was incomplete, but on this point we were not certain.

An examination of the body was made on Aug. 9th at 11 A.M., fifty-four hours after death, in which I was kindly assisted by Dr. Kingsley and my partner Mr. Gairdner, Mr. Nason being unavoidably absent. On opening the abdomen it was seen that there was absolutely no trace of peritonitis. The peritoneum was healthy, saving a little staining and bruising of some coils of small intestine in the left iliac region. Below the vesical fold of peritoneum was a collection of serous fluid, perhaps six ounces, distinctly not urine, and free from the slightest urinary odour. The pubic bones were separated (not fractured) at the symphysis, and gaped something like two and half inches apart. The only portion of the wall of the bladder remaining was a portion of the posterior wall, before and above the prostate, about two inches and a half square. The whole of the fundus and anterior wall of the bladder had simply "gone." It was destroyed, disintegrated. The very prostate itself had evidently undergone crushing, yet the peritoneal fold was uninjured and healthy. A sound introduced per urethram passed, somewhat to my discomfiture, with ease into the space where was once the bladder, and there was no rupture of the urethra. The left kidney was uninjured and normal, but the right kidney was deeply bruised at its upper end, and its supra-renal body crushed and torn. Evidently the man must have been mistaken as to the direction taken by the wheel.

Remarks.—The case appears to me to be one full of interest. The gravity of the injuries sustained, and the absence of such symptoms as one would anticipate, I take to

be very unusual. Separation of the pubic bones without fracture at the patient's age, sixty-nine, must be rare. I think I may take it that the patient had total suppression of urine. But the usual symptoms were absent. Absence of peritonitis in such a case must be unusual. Whether the shock, combined with the injury to one kidney and suprarenal body, be sufficient to account for total suppression of urine, I must leave for abler pathologists to determine. I should state that the right kidney, in addition to the injuries, contained on its lower aspect an ancient cyst lined with an old inflammatory membrane, of about the capacity of a middle-sized walnut.

Stratford-on-Avon.

### A SUCCESSFUL CASE OF NEPHROTOMY AND NEPHRECTOMY FOR SCROFULOUS PYELITIS.

By GEORGE ELDER, M.D.,  
SURGEON TO THE HOSPITAL FOR WOMEN, NOTTINGHAM.

MRS. W—, aged thirty-six years, was admitted into the hospital under my care on April 29th, 1882, with a large fluctuating abdominal tumour. There was no family history of phthisis, and the patient, who was a multipara, had enjoyed fairly good health till two years and a half back, when she first experienced severe pains down the left side and leg, aggravated by exertion and accompanied with painful micturition of scanty and turbid urine. At no time was there hæmaturia. To these symptoms were superadded rigors, fever, night sweats, occasional sickness, anorexia and progressive emaciation, and loss of strength. Latterly she had a troublesome cough with purulent expectoration and dyspnoea. On admission the urine was strongly ammoniacal, muco-purulent, and containing triple phosphates in abundance. The amount passed was small; not more than sixteen ounces in twenty-four hours. Lithia water *ad lib.*, speedily increased the flow. During the first few days, owing to the exhaustion induced by the journey from her home, a considerable distance, to Nottingham, and the extreme tenderness of the abdominal superficies, I confined myself to treatment of a sedative and restorative character. Her condition having somewhat improved, on May 10th, whilst under the influence of an anæsthetic, I examined the swelling, with the result of finding dulness to extend from the anterior superior iliac spine up to and continuous with the cardiac area, and in the transverse direction from an inch to the left of the umbilicus round to the spinal column. The tumour was most prominent in front, and the wave of fluctuation was so distinct that it gave me the impression of the kidney having been converted into one large abscess. A chest examination revealed distinct evidence of tuberculous disease, particularly in the right apex.

The nature of the case having been pretty clearly made out, nephrotomy was performed by the usual lumbar incision. A large quantity of curdy pus was given vent to from two large abscess sacs, into which the kidney had been converted, a friable partition dividing them, which in the course of the operation I broke down with my fingers. A considerable quantity of similar tissue was removed in the same manner. The kidney was found to reach down to below the level of the iliac crest, and its adhesions to surrounding tissues were firm and extensive. Its interior bled freely, which, after washing out with carbolic water (1 in 80), I controlled by plugs of lint saturated with carbolic oil. The usual antiseptic precautions were observed during the operation. There was little shock, and on the evening of the operation it was noted that the patient was quite free from pain and that the temperature had fallen one degree. For some few days the urine was freer from pus than formerly, and the general condition of the patient was somewhat improved. The wound discharged freely. For over three weeks matters were pretty much as above. The urine was never free from pus. The temperature fluctuated between 99° and 103°, and night sweats only ceased when pilocarpine was administered. It is an interesting fact in the case that the temperature in both axillæ was never the same; usually higher on the right; the variation occasionally amounting to nearly two degrees. The sweating was most marked on the right side of the body; both

symptoms pointing to morbid innervation of the cervical sympathetic. An attack of septic pleuro-pneumonia of the right base, which all but ended the record of the case, coupled with the want of benefit following the nephrotomy, strengthened my resolve to extirpate the kidney as soon as the patient's condition warranted it. This I did on June 20th by enlarging the former incision and supplementing it by a crucial. There was very great difficulty in enucleating the kidney from its capsule, mostly experienced at the point of insertion of the vessels. The friability of its structure also contributed to this, and at the same time gave rise to copious bleeding, which pressure by means of sponges checked. I tied the bloodvessels and ureter *en masse* with strong carbolic Chinese silk, and then cut away the kidney. Under the strain of the ligature, the friable tissue of which the pedicle was composed gave way, and for a time the hæmorrhage was appalling. A second and then a third were applied higher up, with the effect of stopping all bleeding, except from a few small arteries which were separately ligated. A few loosely applied metallic sutures, simply used to approximate the edges of the wound, after it had been washed out with carbolic water and tamponed, finished a very tedious operation. Through failure of the spray producer it was not done antiseptically.

The shock after the operation was extreme, so much so that for several hours it was doubtful whether the patient would rally. Frequently-repeated rectal injections of paucetrised beef-tea, and brandy, stood her in good stead. For the first forty-eight hours the scantiness of the renal secretion assisted in making the outlook more gloomy, but at the end of this time the quantity became natural in amount. After the operation its quality became normal, and has remained so ever since. With the above exceptions the patient made an uninterrupted good recovery, and when she was discharged from hospital on account of the annual cleaning she had got quite plump, and there remained of the wound only a small sore.

*Remarks.*—This was a very unpromising case upon which to perform such a grave operation, not only on account of the prostration induced by the condition for which relief was sought, but also because of the state of the chest and the drinking habits of the patient. I regret that the major operation was not at first performed, as by it time would have been saved and the intercurrent attack of pleuro-pneumonia averted. The variations in temperature before alluded to ceased with the nephrectomy, as also the hemihyperidrosis, and before her discharge there was an improvement in the chest symptoms.

Nottingham.

### ON FATTY EMBOLA OCCURRING AFTER FRACTURES.

By R. SCOT SKIRVING, M.B.,  
LATE RESIDENT SURGEON TO THE ROYAL INFIRMARY, EDINBURGH.

THE following case, which I venture to think worthy of record, occurred last winter under the care of the late Professor Spence.

The patient, a temperate and healthy man of forty, was admitted into the Edinburgh Royal Infirmary on Feb. 18th, suffering from a compound fracture of both bones of the leg. The external opening was a very small one; indeed the injury was the minimum of a compound fracture. The wound was dressed antiseptically, and the leg laid on a wire splint. At night, as there was considerable oozing, the wound was again dressed and a compress applied. The next day, after an easy night, the pad was removed and the leg again dressed. In the afternoon of the same day, the patient, having been in conversation with a man in the next bed, ceased to speak; he was supposed to have fallen asleep, but it was soon noticed that something was amiss. His condition then was as follows:—Pulse 130 per minute, full and soft; respiration 24 per minute, regular, and not stertorous; temperature 100° F. On auscultation, a few crepitations might be heard at the bases of the lungs. The face was somewhat dusky; lips pale; pupils contracted, and sluggish in response to light. He was unconscious, and peripheral stimulation was but slowly responded to. The patient yawned at intervals. During the night the respiration was

occasionally of the sighing character described by Cheyne-Stokes. The urine being voided in bed, some was drawn off with a catheter, introduced purposely without oil; this, on examination, contained neither sugar, albumen, nor acetone. Microscopically, a few granular tube-casts and a good many oil-globules were seen. Throughout the following day (the 20th) the patient remained much in the condition just described; but towards night the respiration became markedly quickened, the pulse rose to 156 per minute, and the temperature to 104° F. His face was extremely dusky, and bathed in a copious perspiration. The respiration was now over 60 per minute, and he gradually sank, dying at 1.30 A.M. on the 21st. After death the temperature rose to 105.8°.

On post-mortem examination the following conditions were found:—The pericardial sac contained half an ounce of blood-stained serum. The cardiac cavities were nearly empty. There were numbers of punctiform hæmorrhages on the endocardium of the left ventricle. The lungs showed likewise numerous punctiform hæmorrhages on their pleural aspects; they were slightly oedematous, and congested at their bases. The pleural cavities contained a little blood-stained serum. Microscopically, it was found that the whole of the small vessels of the lungs were plugged with oil emboli, some of them filling several branches of the vessels. The liver and spleen were normal. The medullary portions of the kidneys were congested, and many of the straight tubes contained some yellow oily-looking deposit. Microscopically, the vasa recta were found to be plugged with large oil emboli. In the afferent vessels of the glomeruli well-marked staining of the fat contained in them could be demonstrated with osmic acid; the presence of the fatty matter in the vascular loops of the glomeruli themselves could similarly be made out. Unfortunately a microscopic examination of the brain was not made.

About the same time two other cases presenting almost exactly similar symptoms came under my notice, but in neither could the diagnosis be proved, as no autopsy was permitted. These two cases, both elderly women, had sustained respectively simple fractures of the femur and humerus. The accident had, in both instances, happened in the country about six or eight days previous to my seeing them. Their friends, finding it difficult to treat them at home, had sent them into town in country carts, where no doubt they received a good deal of jolting, as the parts required readjustment on their arrival. About three days after their admission coma came on, culminating, as in the previous case, in dyspnoea and death.

**Remarks.**—In most accounts of this complication of fractures it is almost invariably stated that dyspnoea is the prominent early symptom. In the above cases dyspnoea did not occur till near the close, the cerebral functions being plainly the first involved. I regret that a fuller microscopic examination of the brain was not made, as the presence of oil emboli in that situation, as noted in Professor Czernay's case, would explain to a considerable extent the sequence of the symptoms. On looking over the cases on record, specially those quoted in Drs. Saundby and Barling's paper on this subject in the *Journal of Anatomy and Physiology* for July, 1882, it would seem to be almost invariably within the first three days after the accident that fatal cases of fatty emboli occur—that is, when, from laceration of the tissues, the veins and lymphatics are most liable to take up the oily material. In my last two cases coma did not come on till about a week after the fracture had occurred, but I am inclined to attribute the accident to the disturbance sustained by the parts incident to the transit of the patients to hospital. So far as these three cases go, they seem to show that no great injury or comminution of the parts is necessary to lead to this untoward event, and that its onset is sudden and unexpected. Treatment in cases sufficiently severe to be diagnosed as that of fatty emboli is at present of little avail; whilst prophylaxis in the way of as little handling of the injured parts as possible appears our best indication.

Edinburgh.

**ST. BARTHOLOMEW'S HOSPITAL MEDICAL COLLEGE.**—The open scholarships in science, of the value of £130 each, tenable for one year, have been awarded to Mr. F. W. Andrewes, B.A., Christ Church, Oxford, and Mr. W. S. Whitcombe; and the Jeaffreson Exhibition, of the value of £50, has been awarded to Mr. C. S. Pethick.

## CASE OF CARIES OF THE ATLAS AND AXIS.

By JOHN DEARDEN, M.D., F.R.C.S.E.

THE following case appears to present some features of interest, which I have thought worthy to place before the readers of THE LANCET.

On Dec. 26th, 1881, I was called to attend B. H—, aged forty-two. He is of medium height, tolerably well-developed, pulse and temperature normal, lungs and digestive organs apparently healthy, and of temperate habits. He complained of acute, darting pains up the left side of the neck, extending to the head, taking the course of the trapezius muscle of that side; he also complained of a dull, aching pain on the top of the head, about the junction of the occipital and parietal bones. The pain in the neck was aggravated on the slightest movement of the head. There was enlargement of two of the cervical glands to about the size of a walnut, also considerable rigidity of the muscles of the neck. No difficulty was complained of either in swallowing solid or liquid food, of which he took a fair quantity. The head was drawn slightly forwards and towards the right side; the intellect was quite clear, and there was no impairment of muscular movements in any part of the body. His only complaint was the "excruciating" pain already referred to, and which rendered it difficult to raise himself from the recumbent to the sitting posture, the head having to be steadied by both hands.

The patient stated that he lived in Australia eleven years ago, and had frequently "camped" out on the open ground; also that he had a severe fall from a considerable height

(fifteen feet), alighting upon his back, but "thought he got completely over the effects." He first noticed "the pain" about three and a half years ago, but had been able to attend his business, that of a grocer, up to the time of my first visit. He stated that he never had syphilis. On the date first mentioned he was not confined to bed, but was able to be up and about, taking short walks. In March, 1882, as there had been no improvement he expressed a wish for change of air, so he went to Blackpool. After a short stay he went to Buxton, and placed himself under hydropathic treatment. Finding himself getting weaker and the pains considerably increased, he returned home, arriving on May 23rd. From that date he was not able to sit up more than a few minutes at a time, and that at intervals of nearly a week. On June 23rd the voice became squeaky, and diminished in resonance daily until the termination. Bilious vomiting occurred at intervals; increased secretion of mucus about the fauces and pharynx, which was got rid of with some difficulty; dribbling of saliva from the right angle of the mouth; the above symptoms indicating that the pneumogastric and recurrent laryngeal nerves were implicated in the disease. On June 30th he was seized with violent muscular contraction, raising himself suddenly to the sitting posture, the legs being shot off the bed quite rigidly. He immediately expired.

By his special request the head was examined (Dr. Ruttle of Accrington kindly assisting). On removing the calvaria extensive adhesions were found existing between the dura and pia maters, chiefly situate at the apex; the brain appeared healthy throughout. On looking into the foramen magnum the bare and roughened surface of the top of the odontoid process was visible. An opening was then made

along the posterior border of the sterno-mastoid muscle. A large collection of pus was found on the anterior surface of the spinal canal, but not opening into it, the theca spinalis being whole. The left lateral half of the atlas was extensively necrosed and completely separated from the other portion (the dotted line in the diagram showing the separation), and could be easily removed by the fingers. The right half was represented by only small pieces of necrosed bone, both articulating facets of the occipital bone, and all those of the atlas, were also found to be necrosed; the transverse ligament of the atlas was absent.

It does not need any lengthy description or vivid portraiture to see what the effect of violent and sudden contraction of the sterno-mastoid muscles must be. The head would be drawn forwards, the transverse ligament being absent allows the odontoid process with the axis to slip backwards, crushing the medulla oblongata against the posterior part of the foramen magnum in this case, as there was little of the atlas left—ergo, instant death.

The treatment had been various, chiefly iodide of potassium at one time, quinine at another, now counter-irritation to the nape of the neck, again sedative applications. The only medicine I gave him was quinine with gelseminum and a liniment composed of equal parts of chloroform, tincture of opium, belladonna, and aconite, which he used freely, and expressed himself relieved by it, at least for a short time.

He had been seen and attended by several gentlemen, but the (apparently hidden) nature of the disease was, I think I am right in saying, never discovered during life. I thought the symptoms pointed either to aneurism of a basilar artery or abscess at the base of the brain.

Church, near Accrington.

## REPORT OF A CASE OF SEPTICÆMIA.

By G. STANLEY MURRAY, M.D.

SEEING some peculiar cases of septic poisoning recently reported in THE LANCET, I submit the following, which occurred in my own practice, as being of special interest.

On the morning of the 30th of March a gentleman called at my house to see me, complaining of feeling unwell, though unable to point to any special ailment; describing his state as a general malaise, accompanied by weakness and debility. He was of rather a slight build, aged about twenty-seven, his complexion being dark and much tanned by exposure to the weather. He said he had recently returned from South America, where he had been living several years. His pulse was weak, and he seemed languid and somewhat depressed; complained of feeling drowsy and indisposed for exertion. He had a slight cough, but on examining his chest I could detect nothing wrong. I put him on a mixture of ammonia, strychnia, and digitalis, desiring him to come and see me again in a day or two. On the 2nd of April I was requested to visit him at his house. I found him in pretty much the same state, but complaining of headache, and saying his cough was becoming much more troublesome. His relatives, with whom he was staying, mentioned that he was restless, and they seemed to think he was really worse than he wished them to believe. Again examining his chest, I found slight crepitation in both lungs, accompanied by a hot dry skin. Fearing he was threatened with pneumonia I altered his medicine, and directed him to remain in bed, ordering hot fomentations and poultices to be constantly applied to the chest. On seeing him the following day, I found him decidedly worse, and learned that he had passed a restless night, that his cough had been very troublesome, the pain in the head more intense, and also that he had a slight attack of rigors during the night. On examination I found the chest symptoms now very marked. Making inquiries about his preceding history, I learned for the first time that some years ago he had gone to live in South America for the good of his health in consequence of a tendency to lung affection, where he seems to have led a very rough life, his principal occupation being cattle herding. His food largely consisted of dried beef, as hard and tough as boot leather, which he was obliged to grease and roll up in small quantities and swallow whole in consequence of his teeth being too bad to allow of his being able to masticate it. Indeed, his return to England was solely in order, I

believe, to have his teeth seen to, and the state of his mouth rectified before continuing his life in South America. I then learned that about three weeks before the time I first saw him he was taken up to one of the London hospitals by his brother (a student), and there put under ether, when eighteen stumps were removed by one of the house-surgeons. The next day he went again and had three more taken out, and the following day one, making in all twenty-two teeth removed within three days. His mother told me that afterwards the state of his mouth was dreadful, and for days it was impossible to stay long in the room owing to the smell of his breath. This completely altered the aspect of the case, and left no doubt in my mind that I was dealing with a case of septic pneumonia.

I need not go into minute particulars, but only add that from day to day the patient gradually grew worse, signs of exhaustion setting in. Beef-tea, wine, raw eggs and milk were administered, and ammonia and bark prescribed, but without avail. On the 7th heavy sweating was manifested, and on the 9th his sleep began to leave him. After this the patient became dull and apathetic, only complaining of intense headache and thirst. On the 13th he fell into a state of low delirium, and on the 15th he died.

I cite the case as being one of interest, and as showing the effects of what may be considered a severe operation acting upon an enfeebled constitution.

Putney, S.W.

## A NEW CRADLE,

SPECIALLY ADAPTED TO FIX EITHER TO A BACK-SPLINT OR TO THE LIMB, AS REQUIRED.

By WM. THOMAS JACKMAN, M.R.C.S., &c.

THESE small cradles will be found of great service to surgeons where it is desired to keep the bedclothes raised from an inflamed joint, either to avoid pressure or to increase the efficacy of evaporating lotions, by allowing above the limb a space into which evaporation can take place. They can be fixed securely to a back-splint, or to the limb if no splint is being used, by means of a broad strap of webbing;

The cradle packed for carrying.

the space between the limb and the hoops of the cradle can be regulated as required. The cradles for the knee and ankle are made of wood, and consist of four movable cane hoops three inches and a half apart, capable of being fixed at any desired height over the limb into side bars of wood sixteen inches long. The cradle is further secured by means

The cradle for the knee, adjusted.

of two sliding laths which pass under the limb and are fixed by pegs; these being adjusted, assist in the regulation of the height of the hoops. The whole apparatus is very portable, light, cleanly, and of easy adjustment. The length of the cradle is such that only the inflamed joint is

protected from the clothes, thus avoiding discomfort to the patient, which the large cradles resting on the bed, as at present used, necessarily cause. The cradles, being really one with the splint or limb, can be conveniently used in cases where the limb is slung. The small space the cradle takes up in the bed is a great convenience. For the elbow-joint light angular cradles of stout iron-wire are more suitable; these are fixed to the splint or limb in the same manner as the wooden cradles. Messrs. Ferguson and Co., of Smithfield, are the makers.

Coggeshall, Essex.

### ST. THOMAS'S HOSPITAL.

OBSTRUCTION OF THE BOWELS; UMBILICAL HERNIA;  
PREGNANCY; RECOVERY.

(Under the care of Mr. SYDNEY JONES.)

M. A. S—, female, aged thirty-six, married, was admitted on March 2nd, 1882, suffering from symptoms of obstruction of the bowels. The following history was obtained. She was about seven months gone in pregnancy, and during the whole of that time had suffered from sickness and anorexia; but on the evening of Feb. 26th she was attacked with violent diarrhoea and constant vomiting; she vomited about every ten minutes, and was unable to keep anything down. The diarrhoea ceased next morning, and from that time until her admission on March 2nd nothing had passed, although she had taken several doses of castor oil. She became very weak and prostrate, and the continued retching caused her much pain; the vomit was at first dark green, but on the day before admission became brownish in colour and very offensive. For the last five years she had had a swelling over the umbilicus, which she stated had never been reducible, but varied in size; it had not become larger of late, nor had it been more painful.

She was a very stout, florid woman, in a weak condition, with a temperature of 98° 8' and an extremely feeble pulse, and suffering from constant vomiting, the vomited matter consisting of a dark-brown, very offensive fluid. The abdomen was very large; there was a small umbilical hernia, but this did not present any evidence of strangulation beyond tenderness at the neck, and this was not more marked than the abdominal tenderness, which was generally diffused. There was a swelling in the lower part of the abdomen, evidently the pregnant uterus, the foetal heart being distinctly heard. Pulse 120, almost imperceptible at the wrist; tongue moist, furred. The patient suffered much from thirst. She was ordered one grain of opium pill at once, to be repeated every four hours; the vomiting stopped shortly after the first pill; she was able to keep down a little brandy and milk. About three o'clock she had a good deal of diarrhoea, the bowels acting five times before next morning.

On March 3rd she had not slept at all, but was feeling much relieved, and her pulse was much stronger, and there had been no further vomiting. On the 4th she vomited some greenish fluid in the evening. On the 6th it was stated that she had had diarrhoea for the last twenty-four hours; no vomiting, but continual slight pain in epigastric region, worse before action of bowels; tongue moist, cleaning; pulse 86, fair strength. Up to this date she had an occasional pill, none afterwards. On the 9th she left the hospital quite well, free from pain; no further vomiting or diarrhoea.

### WOLVERHAMPTON AND SOUTH STAFFORDSHIRE HOSPITAL.

SOME CASES OF EXCISION OF JOINTS.

(Under the care of Mr. VINCENT JACKSON.)

CASE 1. *Excision of Hip; Recovery.*—Henry T—, aged three, admitted May 10th, 1882, with hip disease. The joint was disorganised, and a large abscess had formed. On

June 1st the hip-joint was excised. The joint was exposed by a T-shaped incision. The head of the femur was found eroded, and the ligaments had ulcerated through in the front of the joint; the acetabulum was healthy. The wound was washed out with chloride of zinc solution, and brought together by silk sutures, a drainage-tube being put in the most dependent part. Carbolic oil and absorbent wool-dressing were used, and the limb was fixed on an interrupted long splint. On the first evening after the operation the temperature was 102°, and up to the sixth day the evening temperature was close on 100°; after that it was normal. The wound took three months and a half to heal. The patient was discharged on Sept. 16th with an insignificant sinus; his general health was much improved by the operation.

CASE 2. *Excision of Hip; Recovery.*—William C—, aged five, admitted on June 28th, 1882, had suffered from hip disease for a year. On July 13th the hip was excised in the same manner as in the previous case. The bone and cartilage of the head of the femur were carious, and the ligaments pulpy. The wound healed well in two months. The temperature rose to 102° on the third and fourth evenings, and kept a few points above normal for the first fortnight. Health continued good throughout.

CASE 3. *Excision of Shoulder; Recovery.*—James W—, aged thirty-six, was admitted on Nov. 23rd, with disease of the right shoulder. The joint had been diseased for over four months. An abscess had formed, and there were sinuses connected with the joint. On Jan. 18th the shoulder was excised. The joint was exposed by making a semi-circular flap from the deltoid, and the head of the humerus removed below the trochanters. There was pretty sharp hæmorrhage, which was controlled by Spencer Wells' forceps. A sequestrum as big as half-a-crown lay in the interior of the joint. The dead bone corresponded with a cavity at the back of the head of the humerus. The wound-edges were brought together with harelip pins, and a carbolic oil and wool dressing was used. On Feb. 26th the patient was discharged. There were then insignificant ulcerations in the cicatrix and a small sinus. A few weeks later the cicatrix was quite sound, and the patient was able to lift his hand to the back of his head. The patient being nervous in using his limb, it was some time before its motions were strong and vigorous. The temperature went up to 102° 8' on the third evening; normal after the fourth day.

CASE 4. *Excision of Shoulder; Recovery.*—Alfred F—, aged eighteen. In January, 1881, the patient had rheumatic fever, and from that period he dated the disease of his shoulder-joint. He was admitted on March 1st, 1882. He was then suffering from sinuses opening on the posterior margin of the deltoid. On March 23rd the shoulder was excised in the same manner as in the preceding case. The head of the humerus was carious. The wound healed well, and on April 20th the patient was discharged cured. Owing to the perseverance of the patient in moving his arm the limb soon became strong and useful.

CASE 5. *Excision of Elbow; Recovery.*—Francis N—, aged fifteen, had a compound backward dislocation of the elbow on July 21st, 1881. The dislocation was reduced under ether and dressed antiseptically. In August the joint was not doing well. It was soft and pulpy, and a sinus remained which communicated with dead bone. On August 18th Mr. Jackson excised the joint. The epiphyses of the humerus, radius, and ulna were necrosed. The limb was put on a splint for a week and then passive motion was used. The wound healed in a month and the patient was discharged on September 9th, 1881, with good movement at the elbow.

CASE 6. *Excision of Elbow; Recovery.*—Thomas F—, aged ten, was admitted on May 31st, 1882. He was a pale weakly little boy, badly nourished and poorly clad, but possessing excellent spirits. A trivial injury, his mother said, would cause an abscess. In February, 1879, he had knocked his right elbow. The joint became disorganised, and was excised by Mr. Jackson at that time. He now attended the hospital with disease of the left elbow, the result of injury. His health being improved by a good diet and a little wine Mr. Jackson excised the elbow on June 29th. The bones entering into the composition of the joint were carious, and the soft structures friable and pulpy. After the bones had been removed the diseased tissues were cut away with scissors or scraped with a Volkmann's spoon. The limb was put on a splint and kept wet with a spirit

lotion. On Sept. 13th the child was sent to a convalescent home. The wound had healed, and the motion at the elbow was good, considering what flabby muscles there were to work it. The case is almost unique from both elbows having been removed.

### NEWCASTLE-ON-TYNE INFIRMARY.

LOCOMOTOR ATAXIA; NERVE-STRETCHING; NO IMPROVEMENT.

(Under the care of Dr. OLIVER and Mr. PAGE.)

EDWARD C—, aged forty-four, married, a farm labourer, was admitted on March 2nd, 1882, complaining of difficulties of walking and standing, and also of a tendency to fall. Patient had always been a temperate man, never had venereal disease, and had enjoyed good health up to a year ago, when he noticed a pricking and numbness in both his feet. At times the floor felt soft and spongy; his gait was markedly ataxic; he fell when his eyes were closed; had never experienced pains in his joints till his illness began; had never had the girdle pain, but had felt a weakness. Sensation in both legs was somewhat imperfect; patellar tendon-reflex was entirely absent. There was well-marked internal strabismus of the left eye, which, he stated, came on a month or six weeks before. The vision of the right eye was somewhat impaired.

On March 8th Mr. Page cut down upon the left sciatic nerve, and exposed and stretched it, allowing the whole weight of the limb to be supported by it. No ill effects followed the operation. On the 9th the patient's temperature rose to 103.4° F., and he complained of burning pain and thirst. Pulse 128. He recovered from the operation perfectly, and on the 27th was out of bed for the first time; but the difficulty of walking and his attitude were found to be more marked. He remained in the hospital some little time longer, but went out without any improvement having taken place in his symptoms.

## Reviews and Notices of Books.

*Clinical Lectures on Diseases of the Nervous System.* By THOMAS BUZZARD, M.D. Lond., F.R.C.P., Hon. Fellow of King's College, London; Physician to the National Hospital for the Paralysed and Epileptic. London: J. & A. Churchill. 1882.

### [FIRST NOTICE.]

THIS book has two kinds of value. The author throughout it shows a minute and precise acquaintance with that now complex department of medicine—neurology—in its most recent developments. For this very reason he does not dwell with exaggeration on nervous symptoms; he knows them too well for that. It is valuable also because, as the clinically minded reader will easily see, there is displayed in every lecture, without undue prominence over the particular topics of each, a wide knowledge of general medicine. Although comparatively few diseases of the nervous system are expressly considered under their names, the reader from each lecture will not only learn much that is new of the nervous disease there particularly treated of, but will also find that what he may already know of neurology is put in new relations, scientific and clinical; what the reader knows is made more available for use at the bedside. The author deals largely in cases; the narrations and descriptive comments are often so vivid that we might say he places patients before us. The first lecture is a good example of his method. He begins by narrating two cases so as to compel the reader to realise clearly the different diagnostic values of the exaggeration, and of the absence of the knee jerk. Here and elsewhere many highly technical questions are considered. It could not be otherwise. The author deals faithfully with the reader; he does not exhibit the intellectual vulgarity of varnishing over difficulties by popular explanations. The busy man has some natural impatience with details about single symptoms when he has all day long to

treat patients; he very properly expects guidance in his investigation and treatment of individual cases. He will find it here, but he will not find that the complexities of the problems stated are ignored. Much technical knowledge is necessary for bedside work. The experienced man occasionally fails to make a correct diagnosis of a case for want of a little easily learned technical knowledge, when a correct diagnosis of it may readily be made by one of narrower experience and of much less clinical acumen who has that little technical knowledge. He who wishes to become an accomplished musical performer must practise scales, and he who wishes to be a good diagnostician must study symptoms. We should not only study groups of cases, but should also analyse the group into its factors, and see what each means by itself. It is an error to suppose that we can make fruitful generalisations without previous careful analysis of the things to be generalised about. On the other hand, the possession of technical knowledge without clinical acumen derived from close personal experience is somewhat ludicrous, or would be did it not occasionally lead to painful results. To locate the changes answering to a group of symptoms, granting that it were done with absolute accuracy, is of little clinical account if the condition of the patient as to syphilis, Bright's disease, &c., be underrated. But there is no reason why both methods, technical and clinical, should not be harmonised. This harmonisation is indeed very often done after a fashion. We do not call that a good kind of clinical work which consists in merely noting, for example, slight transitory paralysis of some part of the body, and also that the patient is gouty, and then hastily "combining the two" after the manner of the celebrated article on Chinese metaphysics. The author's double method is not after this superficial fashion. For example, in showing the several different clinical circumstances in which the knee jerk is lost or those in which it is exaggerated, he, in an admirable manner, *pari passu* states the several corresponding local pathological conditions; he does this in such a way that the symptoms are easily seen to be dependent on particular flaws here and there in the nervous system. Moreover, he never loses sight of the fact that the spinal cord is but one part of the patient who has to be treated. As an example of a methodical harmonisation of pathology, clinical medicine, and physiology, the exposition deserves high praise; it is not a mere juxtaposition of the clinical and the technical; the dry bones of technicalities in his pages become clinically clothed and live. The organisation is so thorough that it is difficult, with justice to him, to give quotations; only quotations too large for our space would show the orderly continuity which is so characteristic of his exposition of the very complex subjects he deals with. The method by which he conveys wholes of knowledge, technical and clinical, in his narrations of and comments on cases, is so smooth that the reader may easily "read over" very many valuable practical hints for the investigation and management of patients.

In the first of his twenty-five lectures Dr. Buzzard considers Westphal's symptom. In his judgment, to quote from a later lecture, "Westphal's test, the absence of the knee phenomenon, provided that this is associated with fair voluntary power and idio-muscular contraction of the vastus internus muscle (a provision which Erb, as well as myself, has insisted upon) is the most constant and important symptom of tabes dorsalis." He, however, adds a caution regarding the possibility of diphtheritic paralysis, for, as he says, some cases of this kind superficially resemble tabes dorsalis, in some of them there is no patellar tendon-reflex. Two things are to be noted. There may be tabes dorsalis—there may be posterior sclerosis—without ataxy. Again, the knee jerk is lost in other kinds of cases, as the author illustrates profusely in several lectures. After speaking of the absence of the knee jerk in cases of tabes dorsalis, he

points out a source of fallacy. "When the blow is allowed to fall where the plump of muscle somewhat projects above and to the inner side of the patella (the vastus internus), there is a very slight upward movement of the foot. It is important to distinguish this action from the patellar tendon-reflex proper, which is present in health but is lost in locomotor ataxy. Examining the movement, we see that it is slow as well as slight, and is occasioned by the contraction of a very limited number of the muscular fibres of the vastus internus. That this contraction is confined to the muscular bundles of the part struck is shown by the very palpable wave which appears at the spot. The wave is deep, slow in movement, and its direction is obliquely downwards and outwards, corresponding with the direction of the bundles of muscular fibres. It contrasts as strongly as may well be with the sudden and rapid thrill of contraction which may be felt or seen to occur in various and distant parts of the quadriceps in response to a blow upon the patellar tendon in a healthy person." In this lecture he discusses the "deep reflexes" in general, foot clonus among them. In the next lecture the nature of the knee phenomenon and of other so-called tendon-reflexes is considered, and, again, important cases are related in illustration of the questions which arise. Dr. Buzzard thinks the phenomena are really reflex. By means of diagrams he shows how in different diseases the reflex is lost by "fault" seated at different points of the reflex nervous arc—sensory nerve, posterior column, anterior horn, and motor nerves. By this means he simplifies his subject without in the least ignoring its difficulties. He believes that there is ankle clonus in some cases of hysteria; this is a thing of great moment in diagnosis. Were his opinions as to the nature of the knee phenomenon disproved, the lecture embodying his researches would lose little, if any, clinical value, since as symptoms the absence and the exaggeration of the knee jerk are grouped with other symptoms in a methodical manner for diagnosis of the positions of the diseases in different kinds of cases. At the close of this lecture he gives a brief but very excellent account by Dr. De Watteville of the observations and opinions of those who do not consider the knee jerk to be a reflex phenomenon.

In Lecture III. he takes up the subject of acute anterior polio-myelitis, a convenient kind of nomenclature, which tells us that the pathological lesion treated of is inflammation of the anterior spinal horns. Under this name come cases of "infantile paralysis," which disease is now known to have the pathology indicated, and, if we may be pardoned the expression, to occur occasionally in adults. Numerous cases are related. Great stress is laid on the diagnostic uses of electrical currents. In other lectures he does the same, stating clearly his views and describing very carefully this important method of research in particular cases. He points out that in this disease voluntary power may return before the nerves show excitability to electrical currents. Since, in this class of cases, the anterior spinal horns are diseased, he thinks the explanation of the seeming anomaly is that some fibres passing down the lateral column gain the anterior roots without direct connexion with the ganglion cells of the anterior horns. After remarking on the commoner types of acute anterior polio-myelitis, he suggests that facial paralysis is rarely seen from such a pathology on account of the vital surroundings of the facial nucleus; that nucleus may be involved, but rapid death would, he rightly concludes, occur from anterior polio-myelitis of the medulla oblongata. Later on, as we shall see, he considers morbid affections of still higher motor nuclei, which are no doubt homologous with the spinal anterior horns.

Next comes a lecture on the differential diagnosis between certain hysterical conditions and myelitis. Some important

cases are related. The reader will find that the occasional serious difficulties in diagnosis are fairly faced. It is in such cases that shrewd men are sometimes too shrewd. No one should trust solely to emotional temperament, to shock, and the like, in diagnosis. These are valuable aids to diagnosis no doubt; but it is by the application of technical knowledge that the real condition of things in difficult cases may be ascertained with greatest certainty. The man who has a practical knowledge of electrical testing, who has studied the condition of "reflexes" in a large number of different cases, is the one who is least liable to fall into the error of mistaking organic disease of the spinal cord for hysteria, or into the reverse error. Very many cases of disseminated sclerosis in their early, and even in very late stages, are mistakingly put down as being cases of hysteria. It must be admitted that not unfrequently the diagnosis betwixt hysteria and organic spinal cord disease is exceedingly difficult. This lecture certainly, however, makes it less difficult than it was, and may be especially commended to the "busy practitioner."

Locomotor ataxy, or, as the author prefers to call it, *tabes dorsalis*, is considered at great length. Whilst not under-rating the most striking symptom, the ataxy, he shows clearly that *tabes dorsalis* often enough exists without ataxy. There are numerous other tabetic symptoms which can be trusted for the diagnosis of posterior sclerosis when the gait is perfect. We strongly commend the following: we have no doubt of its accuracy. It is what an able and original-minded physician of large experience has concluded, from hard and steady work, on a matter of direct practical importance. By carefully pondering this one short paragraph, many practitioners will save themselves from the regret of having misinterpreted cases of *tabes* before time made the correct diagnosis of *tabes* for them. In a word, we say to them, Do not wait until the supervention of ataxy makes the diagnosis of the real condition of a patient for you.

"It appears to me that, in the present condition of the question of *tabes dorsalis*, we are not quite warranted in saying of a case which does not show any ataxy that it has not yet arrived at a certain 'stage.' Our grounds for dividing the course of this disease into different stages, appear to become less and less secure as we observe that various parts of the sensory nervous system may be involved in degrees of intensity which bear no fixed relation to any chronological order. Although the point can only be determined after a considerable lapse of time, it seems most probable that ataxy of gait is no more a necessary symptom than optic atrophy, although it is a much more frequent one. Whilst allowing, then, this highly characteristic symptom when present to retain all its former value for diagnostic purposes, it is well to recognise the fact that not only may the incoördination of movement be entirely wanting, but some other symptom which may not ordinarily be at all a striking one may come to occupy the most prominent place. In these circumstances it is apt to absorb the attention of the observer to such a degree that, without some considerable care, the general disorder, of which it is only a symptom, is masked, and the symptom itself is liable to be referred to some entirely different pathological condition."

THE parishioners of Marylebone appear resolved to remedy a defect in their parish which has long caused complaint—viz., the want of a proper public mortuary. A communication from the Local Government Board has been received by the vestry, in which objections are pointed out to the mortuary in Paddington-street, chiefly on account of the absence of accommodation for conducting post-mortem examinations or provision for the holding of coroners' inquests. The matter has accordingly been removed from the charge of the select committee, who seem to have done nothing in it, and referred to the Sanitary Committee, from whom it is to be hoped it will receive more prompt attention.

**Abstracts**  
OF  
**INTRODUCTORY LECTURES**  
DELIVERED AT THE  
**MEDICAL SCHOOLS OF LONDON**  
AT THE  
**Opening of the Session 1882-83.**

**ST. GEORGE'S HOSPITAL.**

INTRODUCTORY ADDRESS BY DR. HERBERT WATNEY.

AFTER referring to the loss sustained by the medical school through the resignation of Dr. Barclay, the lecturer spoke of the new examination instituted by the Royal College of Surgeons to be held by the teachers of anatomy and physiology. He considered that it will be only a guide and help to the ordinary hardworking student, and will be so easy as not to discourage any, but will prevent the first year of student life being partially wasted, as has sometimes been the case. A short account was then given of some of the sciences bearing on medicine. He said anatomy, the foundation of the medical sciences, can now be satisfactorily studied by all who enter our profession; but this has only been the case during the last hundred years. It is, however, a question whether the pendulum has not now swung a little too far; whether the examination in the minor details of anatomy, and, consequently, the teaching of these details, have not gone further than there is any need; whether the oldest science does not engross too much of the student's powers, not as regards its essential principles, but for its minutiae. And the very strong opinion of William Hunter was quoted to the same effect. Dr. Watney then dwelt on the importance of physiology and its fascination as a study, bringing us face to face as it does with the problems of life and death, and leading us to "the borderland of the material and the immaterial"; but he pointed out that the same evil of overrating the importance of minutiae is sometimes met with in this study, saying that there is a physiology whose devotees seem to think more of the instruments or the specimens, soon to be set aside for newer and better ones, than of the valuable observations obtainable by such means. Pathology was described as being at present divided into two great branches—one, which may be fairly classed as belonging to the two sciences of anatomy and physiology, dealing with the anatomical or physiological changes wrought in the body; the other quite different in its character, aiming at much deeper knowledge, seeking to discover the causes of certain diseases, even, it is said, cultivating these causes, and so controlling them that they become innocuous. It is probable that vaccination is a remarkable instance of this method of rendering a virulent poison harmless by means of a series of cultivations in the bodies of the lower animals. The great necessity for the study of pharmacology was next referred to, and the study of *materia medica* was alluded to as being only a "survival." The value of hygiene was then spoken of, and the change in the death-rate of the population during a number of years was considered a clear indication that hygiene is giving us most valuable aid in our struggle with disease. The lecturer remarked that during the time that the sciences bearing on the healing art have been developing, much work which may truly be called scientific has been accomplished in medicine and surgery; but we are still obliged in great measure to act from the basis of experience and from a knowledge which, though it has the authority of time, has never had a scientific foundation.

He then attempted to answer the question, What should be the due relationship between the scientific and the practical in the training of the student, and in his after-life as a medical man? After showing that there is generally an intimate union of these two apparently opposite principles in those whom we regard with the greatest respect, he proceeded: "A scientific education implies study with a view to the acquisition of knowledge apart from any ulterior object—that is, seeking to know what has been accomplished in any subject, and to be so placed that future progress is possible, supposing that the patience and abilities of the individual are equal to such

advance. It should, however, also include the acquisition of the scientific method. Practical education implies the study of any subject in such a manner that we can bring our knowledge to bear at the present or at a future time. The scientific worker is remarkable for his dissatisfaction with the present state of our attainments and his desire to know more; further, he is noted for the accuracy of his knowledge, it may be only in a very limited field, but in that field he is not only aware of what has been discovered, but of the manner in which the discoveries were arrived at and the extremely unsatisfactory basis on which much of our supposed knowledge rests. On the other hand, the sympathies of the practical worker are with that portion of mankind which exists near and about him, and his energies and abilities are concentrated to produce, with the present fund of knowledge, the greatest results and the utmost benefit. He said it cannot be too strongly insisted on that the study of the sciences bearing on medicine will not alone enable you to become a safe guide in surgery or medicine; these last have to be studied, they have their methods and instruments of precision, some of which, such as chemical reagents, are well known to the chemist, others, as the thermometer, to the physicist, yet it is impossible for any physicist or chemist, or even for those who have studied the sciences more nearly allied to our profession, to understand the value of certain phenomena taken in conjunction with others, unless they have studied medicine itself. "Therefore, in answer to the question, What is to be the relationship between the scientific and the practical in your course of study? I would say, If you wish to follow the practice of medicine do not devote too much time to the study of the sciences. They are to be only portions of your education; they are the sources of much knowledge, but they are not the knowledge itself."

Dr. Watney then continued: "Science is not liked by some because it makes so little of the individual opinion, and treats so lightly that power which some men have of enforcing their views and persuading their fellow men. In politics and in art we see the immense influence of the individual—how his word is taken almost as law. Yet the habit of accepting without question what is told us has been the most fatal stumbling-block to the advance of medicine. The reputation of Galen helped to retard for centuries the advance of anatomy; and the deference paid to authority during the Middle Ages did incalculable injury to the large body of practitioners of that time, who learned to work in a mechanical, self-satisfied manner, impatient of any advance, unobservant, allowing centuries of time to pass and millions of sick folk to be under their hands, without attempting anything further than to struggle with one another as to who should be the greatest, 'seeking rather to conquer their opponents in argument than to penetrate the secrets of nature.'"

"It is, however, easy, standing on the platform of our present knowledge, to point out the failures of the past generation, but the question which every thoughtful man will put to himself is, not what were their absurdities, their mistakes, but what can we learn from their failures? It is clear that ability will not prevent mistakes, and even absurdities; for many of the older practitioners were men of great genius, and we have no proof at all that there is more ability now than formerly, nor can anyone imagine that we take more pains than formerly were taken. Must we, then, assume that we have a better method? And yet who can say that he has a better method than Harvey? At last we are driven to the conclusion that medicine is a progressive science, and that we are profiting by the information obtained by others, reaping the fruit sown by them at great expense, after many failures and much disappointment."

"Now, with regard to the question, What is to be the relationship between the scientific and the practical in your future life? I would urge that everyone who practises the medical profession should, besides his ordinary avocations, work in a scientific manner at some subject, and aid in the advance of knowledge. It is very necessary that you start with one humbling thought, that you cannot finish your studies, and that you must go into practice to a certain extent incompletely prepared. It is impossible that you should be a good anatomist, or physiologist, or pathologist, or a good practitioner, when you leave this or any other school of medicine. It has lately been debated whether four years are enough for study, and whether the curriculum ought not to extend over five years. Surely ten years would not be enough to master anatomy and physiology alone, and by the end of that time so many advances would have been made that you would

hardly be able to keep your knowledge current with the times; thus physiology is being split up into various departments, and few are skilled alike in physiological chemistry, in experimental physiology, and in the use of the microscope. If you grieve at the thought that your knowledge must necessarily be imperfect, console yourselves with the fact that it is found, in planting trees in exposed and windy situations, that it is necessary to take quite young and small ones, for that the older and taller trees, which have had the advantage of good surroundings and have been accustomed for a long time to cling to their supports, do not grow so well in such situations as shorter trees, which, though smaller when first put in, eventually become more vigorous. So the well-taught but not too fully-taught student, though at first he may seem behind the artificially-forced stripling, will send his roots down deeper, and obtain a firmer hold in any new undertaking he may choose. And you are sure of true success. Your aim will be to allay pain, to prevent the effects of wrong-doing, and to combat death. It is true your patients will suffer for their follies, will at times be wrong by pain, and will, at length, all die; yet you will be successful, because you will not set before yourselves, or others, the false chimera that you can finally resist death, or prevent its painful accompaniments. You will accomplish what you hoped to do—alleviate pain, in a great measure prevent the effects of evil, and delay the advent of death himself. Yes, you will succeed; but let not that be our only success, great as it may be. We may look forward to the time when we shall meet Him and be with Him who alone has conquered pain and sin and death, and who has won a complete success for us.

#### LONDON HOSPITAL.

ADDRESS BY MR. JONATHAN HUTCHINSON.

THE address of Mr. Hutchinson was given at the conversation, and was devoted almost entirely to a sketch of the life of Thomas Carlyle, with a critical survey of his work.

"About a year ago there appeared," said the lecturer, "immediately after the death of one who was perhaps, take him for all in all, the greatest man of the present generation, two volumes of *Reminiscences*. In these we found amongst much that we valued much also that needed excuse, and some things that it was hard to forgive. Those, however, who were most pained by certain passages in that work will, I cannot but think, have been greatly relieved by the reading of the two volumes of biography which Mr. Froude has just given us. In these latter we have, full and complete, the story of Carlyle's life, his struggle, and his victory; and the hero now again claims, if I mistake not, that lofty position in our estimation from which he had been almost threatened with dethronement. Here we are permitted to see, in full disclosure, the sources alike of his weakness and his strength, and our marvel at the work which he did, and at the uses to which he put his troubled life rises higher than ever. The unconquerable independence, the industry, the faith in the future, unclouded in the main by the deep-rooted melancholy of his nature, the sense of duty in his work, are features in which the character of Carlyle attains sublimity. His letters to his wife and to his mother, and perhaps above all those to his brother John, claim our admiration in the very highest degree. Especially to all young men, and to all young medical men, for they were addressed to a struggling young physician, I would commend his letters to his brother. .... Over and over again, in his letters to his brother and in his entries in his own diary, Carlyle enforces the paramount duty of keeping clear of the 'gig-man' spirit. In one of his most pathetic letters to his wife, when their prospects were at the lowest, and he is endeavouring to incite her fortitude to further effort, he reminds her with pride that her soul was never that of a 'gig-maness.' .... The words in question are designed to denote merit and respectability as indicated by externals alone and without regard to the inner character of the man. To be above the gig-man spirit is to be capable of maintaining our proper position in the forum of our own feelings irrespective of success in life, and to be in the habit of according such position to others quite irrespective of theirs. It is to take measure of the soul rather than of the body's trappings. There is yet another word frequently occurring in these letters which it may be necessary to explain. It is the German word *entsagen*. Carlyle repeatedly congratulates his brother on having learnt the meaning of

this word, and in one place he writes 'My main comfort about you is to see the grand practical lesson of *Entsagen* impressing itself in ineffaceable devoutness on your heart.' He regards *entsagen*, he says, as the first lesson in all true life. With Mr. Froude's help we may interpret his meaning to be that we should in the first place learn the doctrine of renunciation of worldly gains and become able to say firmly that we can do without any and all of the various pleasant things with which the world usually rewards those who render services to it. It is, in fact, to learn, as we find it expressed in 'Sartor Resartus' 'to do without happiness and to find in its stead blessedness.' .... Were we to attempt to sum up in brief the secret of Carlyle's strength, I think we should have to say that it consisted in his perception of the reality of things. This was a feeling which was ever present with him. Men were real to him, spirit-possessing beings, never wholly without the capability of affection, never even in the degraded condition of part-ridge-shooters or gig-men, losing all share in the divine element of life. Their differences, too, were real and must be taken carefully into account. The world was real, the universe real, the past had really been, and the future would most certainly come. In truth, this sort of perception is the secret of strength in us all, and its absence is the cause of all weakness. It is the very basis of all motive and of all effort. It measures our devotion to truth and our belief in its value, upon it is rooted the distrust of all shams, the hatred of all forms of lying. The gospel of duty, self-restraint, and devotion to work, was one which Carlyle had well learned, perhaps no man ever better. But there was a great failing in his attainments, one which marred the happiness of his life, and which not only robbed him of the reward which was his due, but considerably diminished the usefulness of his teaching. He had not learned what we may, I think, without irreverence style the Religion of Patience. By patience I mean not the mere passive virtue of endurance, which indeed is not unfrequently no virtue; I mean rather the ability, when we have done our best, under all possible circumstances to rest undesperingly and trustfully for the result. Dare I venture for one moment to assume the prophet's mantle myself, I would foretell that the worship of patience in this exalted sense is one upon which the present age is about to enter. If we glance back over the great mythologies of the past and note their hidden meanings, we shall observe the worship under various types, of various forms of power, of beauty, and of virtue. In the earliest ages the gods were symbols of force; they did, and not always beneficently, the great deeds which controlled the destinies of men. Next, as in such types as that of Hercules, we see force combined with human-heartedness, but still force, gross and almost purely physical in its efforts. Side by side with this sprang up the worship of beauty, especially in human and female forms, and the shrines of Juno, Minerva, and Venus, under various names in different climes, claimed their countless votaries. As the moral sense grew and human sympathy expanded, the unsatisfying nature of these Religions of the external became felt and the world witnessed events such as the self-renunciation of Buddha and the advent of what has been well termed the Worship of Sorrow. In these sublimely loving creeds there were, however, elements of weakness and of unfitness for the everyday work of the world, and the pendulum of human sentiment, as it was sure to do, swung back again towards an exaggerated estimate of physical force and natural beauty. In truth, the worship of these was far too deeply rooted in our very being for it to have ever been put aside. The other had been added, but these had not been dethroned. Nor will the introduction of a new goddess effect the displacement of any one of her predecessors. We may pay vows at the altar of patience without ceasing also to render due homage to courage, energy, and physical vigour, and without bating one jot of our admiration for the charms of external beauty, or of our reverence for that glory of soul which can find the happiness of life in pouring blessings on others. .... Part of Carlyle's impatience was creditable, being due to the greatness of his nature in other directions, his keen appreciation of the true making him correspondingly intolerant of what seemed to him false. This topic of life-patience is one which concerns us as medical men, perhaps, more directly than some of the others which I have mentioned. To a large extent impatience of life in its various forms—acute, chronic, and paroxysmal—is undoubtedly a

result of inherited organisation or of derangement of health. Its cure, if cure there can be, must be sought from physical means, and not from any new development of opinion or fresh insight into the order of the universe. That, however, the influence of opinion and of creed upon the mental health is often very great, no one knows better than the medical observer. .... I have said that Carlyle was impatient, and that he formed, under the influence of prejudice, very unjust opinions on some topics. Amongst others, he spoke of the doctrines of Darwin as too contemptible to be worth a moment's consideration. In putting them thus scornfully aside, I think he missed a main source of comfort in life. The truth is that what Carlyle himself was proclaiming in the language of the mystic, Charles Darwin was explaining in the language of science. Carlyle was asserting that there is a spiritual power in nature, was bidding us reverence that power as supernatural, and as working through rough and mysterious ways towards certain and definite good. Darwin, looking at the same facts from a biologist's standpoint, explained how this result did indeed come about, and that, too, through the simplest and most unmythical ways. It has been thought by many, by believers as well as sceptics, that Darwin's explanations are melancholy ones, and that they would in short land us again in regions of mere brute force. I cannot think that this view is correct. Darwin did not impose any new 'law,' he simply interpreted the facts of nature, and nature, whether his explanations be true or false, will go on in the future as it has done in the past. .... Many ages have had their prophets and their seers, those who in the uttermost earnest have set themselves to deliver the messages with which they have been entrusted. If I am not mistaken, however, no age and no country has been more favoured in this respect than our own. I will name to you four, not that they are the only ones, but rather that they stand foremost, and because, also, I think they may be fitly held to represent the four divisions of social religion to which I have referred. To Carlyle, of course, we give the chief place, and to him we assign the priesthood of the worship of Strength. .... There can be not the slightest doubt as to whom I ought to name as our Seer of the Beautiful. What Carlyle has done for the worship of Strength, his pupil, John Ruskin, has done for that of Beauty. .... To Wordsworth must, I think, be assigned the office of latter-day priest at the shrine of self-renunciation and human sympathy. .... If we go to Wordsworth to learn sympathy we must, I think, turn to another poet for initiation into the cultus of Life-patience. In this noble worship, if I mistake not, Robert Browning stands as chief priest."

His reasons for the above selections having been set forth, Mr. Hutchinson concluded as follows:—"Now, gentlemen, students of our college, in conclusion, I can but hope that none of you will consider that I have unduly neglected an opportunity of speaking to you on subjects directly pertaining to your education. I hope to have other opportunities for doing that. It has seemed best this evening to address you on topics which concern us all as men. I might have devoted the hour to eulogy of the profession which you have chosen, but surely it needs no praise. So, also, I might have praised the school which you have selected, and paid compliments which would have been very sincere, however blunt, to those at present concerned in its management and to my colleagues. But here, again, facts speak for themselves, and you are familiar with them. I have preferred to try to find you motives for work and to give you strength and confidence in study. If now I were to sum up in one sentence what I have been enforcing it would be this: the secret of all noble life lies in belief, and the characteristic of all noble minds is the vigour with which they believe that which is true. Try to attain belief in the reality of all things, so shall you never want for motives, so shall you be able to live and work without hurry and without sloth. Finally, permit me to commend to you this formula: prize strength, love the beautiful, practise self-denial, and be patient."

##### INTRODUCTORY LECTURE BY DR. CAYLEY.

DR. CAYLEY commenced by alluding to the great calamity which had just occurred, and said: "A blow has fallen upon us so suddenly in the death of Dr. Lyell, who was to have delivered the address to-day, that we are unable as yet to estimate the extent of our loss. When we remember his

great abilities, his untiring industry, and his blameless and pure life, we feel the bereavement great indeed. We are, however, in the position of soldiers on the field of battle, where if one is struck down there is no time to indulge in lamentations, and like them we must close up the ranks; and although we must feel the proceedings of to-day to be indeed clouded with gloom, we must endeavour as far as we can to go through the necessary business and not allow the occasion to pass without a few words of advice to students from their teachers."

After referring to the object of the meeting, and wishing "God-speed" to the neophytes in medicine, the lecturer went on to notice the various points of view from which medicine may be regarded; first, as a science, in which they investigated the growth, structure, and functions of the human body, and the various causes by which it was disturbed; next, as a practical art in relation to the cure of disease and all the means for its prevention; and, lastly, as a profession in which those who entered it might hope to pass an honourable career. Of all these objects the one most liable to misapprehension, especially on the part of the outside world, was the scientific one. The pursuit of knowledge in a scientific spirit aimed at the investigation of natural laws rather than any immediate practical advantage. Medicine was now threatened with a new danger, the arrest of experimental research, and it behoved the profession to meet the arguments of their opponents and to defend the cause which they believed to be so essential to the welfare of mankind. The objections raised to experimental research were based upon a misconception of the whole system of nature. We see through the whole domain of life an inter-necine struggle for existence, and man himself extirpates without scruple those animals he finds injurious to his predominance. He kills them for clothing and food, makes slaves of them, and slaughters them by thousands for mere amusement. If Harvey had lived in the time of Victoria (instead of that of Charles the First), under the present restrictions he would never have discovered the circulation of the blood, whilst the deer upon which he would have experimented would probably have been hunted to death by the royal stag hounds. Turning to the practical side of medicine, the lecturer impressed on the students the fact, that their profession required all their energies in the study of its various branches, and in the ordeal of examinations. He counselled them to let this pursuit be foremost in their thoughts, so that they might not devote too much time to mere amusement. Many people thought the medical profession was overlooked in the distribution of honours, but they were cut off from the main source of honour—e.g., high office in the State—which was beyond their sphere of activity. Neither were they in a position to acquire wealth, but must be satisfied with obtaining a competency. On the other hand, into whatever house they entered they went for the benefit of the sick, and they would win not only the respect, but the esteem and love of their fellow citizens. If so fortunate as to acquire this, they might well let the rest go, and they should so spend their time as to be worthy of the hospital in which they had been trained, and of the country of which they were citizens.

#### ST. MARY'S HOSPITAL.

##### INTRODUCTORY ADDRESS BY DR. THOMAS KING CHAMBERS.

THE lecturer began by saying that an "introductory" is usually delivered by some active junior member of the staff, who has at his fingers' ends all the special advantages which a new pupil at St. Mary's inherits. He, however, had not that personal experience now, and, in fact, was saying the farewell to his old chair, which illness prevented him saying a few years ago. He had, therefore, selected as his subject "The Relation of the Medical Student to the General Medical Council." He was the junior member of that mysterious body, and therefore supposed to be a proper person to introduce it. The Medical Council's most important duty is to watch over the student, to see that he gets justly that education for which he gives his time and money, to show him the path by which he may become a useful and honoured Englishman, and to make that path as easy and direct as possible. That the Council is performing this duty is graphically shown by contrasting the medical student as described—and truly described—by Charles Dickens, and the medical student of to-day. "I will take this opportunity of

giving you a few words of warning. Do not on any consideration make the mistake of accepting places as assistants before you have passed the qualifying examinations. By so doing you will be mixing yourselves up with a set of men who have lost all ambition of being legitimate practitioners, who have degenerated into mere drudges, whose manners and morals and education unfit them to be your companions. You run great risk of becoming like them and being equally despised; and by delaying your fitness for going up to your final examination, you are making your education more tedious, and therefore more expensive in the end. But when you have cleared examining boards off your minds, then, indeed, I do not know a more valuable part of education than that which can be got by a good assistantship. For having learnt systematically and thoroughly how to learn, you will understand quickly the details of the application of your knowledge and profit in direct proportion as you have not muddled your brains with those details beforehand. They are selfish and cruel persons who tempt you to be unqualified assistants. They do it for their own dirty profit, and it is a very bad bargain for you." Dr. Chambers then pointed out that a very great portion of this improvement of the *status* and comfort of the medical student was due to the action of the Medical Council in forcing upon parents and guardians the duty of giving a sound preliminary education to those destined for the profession. "When a student feels the satisfaction of ease in acquiring technical knowledge and a fitness for belonging to the cultured classes which early education bestows, he should not forget his indebtedness for it to the Medical Council. To the influence of the Medical Council is also due another great comfort to the student—the substitution of several examinations for that one which used to hang like a sword of Damocles over his whole career. Perhaps some may exclaim that this is worse and worse—it is the hanging up of several swords instead of one. But that is a superficial view of the matter. It is in reality a 'dilution' of the single examination, which spread over several years ceases to be a legitimate object of fear altogether. If an old man's pupilage could come over again he would certainly choose that body to examine him which most divided its examinations; for he knows that he would eat, drink, and sleep the better for his choice. Then, the curricula of the different licensing boards have been the subject of serious thought and arrangements by the Council. They are made as harmonious and as equal as possible. The student may rest assured that by following them strictly and honestly he will be making the best use of his time to ensure success in the examinations; and success in the examinations is a pledge to you that you have those qualities which lead to success in after life. Do not, my dear fellow teachers, take umbrage at what I have said as to the need of keeping examinations constantly in view. Observe the signs of the times; examination, as an engine of education, is becoming more and more powerful, and, wisely or unwisely, all orders of men are agreed in reposing their confidence in it. Trust has begotten a resolve to deserve trust; and I feel sure that the schemes of instruction suggested by the medical examining boards and approved by the Council are the best guides we can have. Your responsibility is very great; yet it is not too great to be borne by the exercise of the simple commercial virtues of (1) sobriety, (2) punctuality and (3) attention to business. Let your 'sobriety' be known unto all men in deed, in thought, and in speech. Words, as Homer tells us, have wings, and they fly to the ends of the earth. You can hardly fail to have been startled, if not awestruck, by the quotation of some chance sentence of yours out of a lecture or conversation in the mouth of an old pupil or pupil's pupil; it may reappear in the colonies or come back from America. Take care, then, that is a true message which thus travels forth. Avoid all paradox, exaggeration, or inexact illustration, however brilliant. Be assured it will haunt you, and start up when you least desire. 'Punctuality' is the homeliest of virtues, but the neglect of it by teachers is visited with very public loss of reputation. Pray remember that every minute students are kept in waiting is most likely occupied in criticising you, and in commenting, not favourably, sometimes not quite fairly, upon your person, your manners, and your teaching. I will leave you to judge if that conduces to your influence for good. 'Attention to business' is an expression which seems to demand an opinion as to what your chief business is. You will, of

course, say it is to make pupils into the best and safest practitioners that the time afforded us allows of their being made. Yet teachers differ somewhat as to the surest mode of attaining this end, and, possibly, some of you may dissent from my concluding sentences. A frank submission to the mastery of the inevitable examiner is, I am sure, the wisest course, and I expect this will lead in the end to changes in our method of communicating instruction. It must gradually become less professorial and more catechetical or tutorial. I mean that a considerable part of the time devoted to each study should be occupied in question and answer on matter previously prepared by the class. The subject should be explained and enforced from the chair; not, as of old, given out fresh from the chair and learnt up by notes afterwards. The catechetical method gives a shrewdness in catching the point of a question and a facility in answering it which contribute greatly to success in examinations and to readiness in the emergencies of future life, and by bringing their two minds into more immediate contact it gives the teacher a power of measuring the progress and declaring when sufficient advance has been made to sanction the issue of a certificate of sufficient attendance. To try to gain this early would be a sharp spur to early diligence, and would ensure the presence of minds as well as bodies on the benches of our theatre. Students complain, not entirely without reason, of the number of lectures they have to sit out and of the days broken up into fragments and consumed. If you adopted this plan the remedy would be in the complainer's own hands, for he would only have to show a mastery of his subject to be free for the rest of the session and give his time to reading and ward-study. I am satisfied, by observation not limited to medical schools, that the catechetical is, of all methods, the most sure and effectual for teaching Englishmen. I should not have dared to say so much had I not observed tentative efforts made here to introduce the principle I have advocated. To succeed, the efforts must be combined, and, my new young friends, they must be co-operative: assistance on your part, hearty and forbearing, must be given or the experiment will not be a fair one." The lecturer then took leave of the theatre, where, he said, he had begun to lecture before the plaster was quite dry upon its walls, and where he left one of his first pupils as his successor.

#### WESTMINSTER HOSPITAL.

##### INTRODUCTORY ADDRESS BY DR. DE HAVILLAND HALL.

AFTER expressing his approval of the custom of opening the session by addressing a few words of advice to the students who are commencing their medical studies, of encouragement to those already known, and of farewell to those about to take flight from their alma mater, Dr. Hall pointed out some of the advantages of a small school. He thought that Westminster had deserved well of several of its larger rivals, and cited the names of men formerly on its staff who had migrated to other hospitals carrying with them the experience they had acquired at Westminster. It should not be forgotten that, in the language of one of the old reports, Westminster is "the parent of all the medical and surgical charities of these kingdoms that are supported by voluntary contribution." Then, addressing the students who had just entered, Dr. Hall pointed out the necessity of settling down to work steadily if they would avoid the temptations incidental to the life of a medical student. The lecturer regarded the examination at the end of the first year, recently instituted by the Royal College of Surgeons, as likely to be a useful check to the lazy student, and serve as a beneficial stimulus to all. In insisting upon the mental discipline of a thorough course of anatomy, and the habit of exactitude fostered thereby, he said that it was the anatomy learnt by actual dissection which was required, and not the counterfeited obtained by the aid of cram-books and tips. He therefore advised that every opportunity of dissecting should be seized, so as to get a practical knowledge of the subject as well as to acquire the manual dexterity, which he stated to be almost as important to the physician as to the surgeon. Dr. Hall discountenanced attendance in the out-patient rooms and wards before the primary examinations had been passed. "If you begin to go round the wards before you are capable of understanding and taking an intelligent interest in what you see and hear, you will in all probability

acquire the habit of doing things in a casual manner, which is destructive to anything like thoroughness." He therefore advised that only the minimum amount of attention required by the regulations of the College of Surgeons should be devoted to surgery until the primary examinations had been passed. He urged all students to make an effort to pass the first examination of the Royal Colleges of Physicians and Surgeons within the first two years, so as to leave two whole years for the practical part of their studies. He also insisted upon the importance of students having a clear understanding as to what degrees or diplomas they intend taking. "Much time is lost and inconvenience caused by the student discovering, after he has started on his career, that he requires a degree in medicine, or that the Fellowship of the College of Surgeons will be necessary. When you are once launched into practice it will be almost impossible for you to obtain a British medical degree (unless you be over forty), as all the universities except the London require residence, and the curriculum of the latter puts that out of the question." Dr. Hall was distinctly in favour of enforcing attendance at lectures; he considered that lectures could lay stress on the more important points, and that in such a progressive science as medicine attendance at lectures was the only feasible way for students to keep abreast with the daily increase of knowledge. He advocated the plan of taking short notes at lectures, to be amplified at night. In speaking of the necessity of thoroughness, he said: "If you begin your medical career with an inaccurate knowledge of the sciences on which medicine is based be sure that you will never practise your profession with anything like satisfaction to yourself or advantage to your patients. At the best you will be little better than empirics."

"Of equal importance with the mental training is the necessity of seeing that the physical needs of the body receive their due share of attention." In speaking on this subject Dr. Hall drew attention to the demands upon a medical man's energy and decision, and to the importance of good health, unless the doctor is himself to fall a victim to the very disease he was called upon to treat. As a means of preserving health regular exercise was highly praised, and students were advised as much as possible to make their recreations such as would take them into the open air, and to avoid the billiard-room. In speaking of purity of life, Dr. Hall said: "If your purview is limited to this world only it is worth your while to lead a moral life. Infringements of the moral law are frequently visited, as, alas! you will too often have an opportunity of seeing, by immediate punishment, and by what I consider as more awful a punishment, which in certain cases is shared by innocent victims. Ruined health, early death, or premature old age, to say nothing of the misery and wretchedness communicated or transmitted to those nearest and dearest, have been in many instances the lot of youth who commenced life with bright prospects; so true is the apostolic saying, 'The wages of sin is death.'"

After a few words of caution as to the choice of friends and on the means of keeping out of the way of temptation by being always busy, Dr. Hall proceeded to discuss the different openings possible to the medical man. He assumed that the majority of his hearers were destined for general practice, and he told them that with fair education, good health, and tact, they might rest content that they would earn for themselves a living, and in many cases a very comfortable one. He strongly advised those who were intended for general practice to go as assistants for a time before starting on their own account, so as to learn something of the requirements of general practice. He then spoke of different modes of starting in practice. Those who were anxious to see something of the world before settling down had a wide field of choice—i.e., there were travelling appointments to be had or surgeoncies in the mercantile or emigration services. For those who wished for work of a still more permanent character, the three branches of Her Majesty's service were open—viz., the Army Medical Department, the Indian Medical and the Naval Services. "Ten years ago and less the Indian Medical Service was the only one which attracted good men; the two other services were literally starved. But of late years, owing to the increased pay and improved regulations, there has been a keen competition for all these services. For instance, at the last examination, held in August, there were ten vacancies for the army and thirty candidates, the same number of vacancies for the navy and twenty candidates, whereas for the eight vacancies in the Indian Medical

Service there were forty candidates." Dr. Hall then discussed the respective advantages of the different services, and pointed out that there was ample scope for scientific workers in the department of public health. After reading the Hippocratic oath *in extenso*, he concluded his address as follows:—"The enlightened morality of the oath, and the admirable rules laid down in it for the conduct of the medical man towards his patient, leave little to be desired, and if you only act up to the spirit of this document, over two thousand years old, you will attain, if not wealth, at all events the respect and esteem of all with whom you come in contact, and a happy hereafter."

## THE PROTECTIVE POWER OF VACCINATION.

To the Editor of THE LANCET.

SIR,—In your last issue, under the above heading, you refer to the importance of inoculating vaccinated persons with variolous virus to furnish undeniable evidence of the protection afforded by vaccinia against variola. This has been done, as you know, over and over again, especially during the earlier years of this century; and if such a test would convince "anti-vaccinationists," or would inspire confidence in vaccination among those hesitating as to its efficacy, I would refer them to the literature on vaccination and small-pox issued in Dr. Jenner's time, in which they will find scores of experiments recorded like those suggested by Dr. Cory and Dr. Mitchell. Those opposed to vaccination who will not listen to reason need no further notice; but others, who have perhaps thought and read more on the subject—who at all events are amenable to conviction—will say, inoculated variola is a very different disease from contagious small-pox, and is indeed, so mild a form that it was employed for many years as a prophylactic against contagious variola. This brings me to record an instance which occurred to me some years ago, and no doubt many such experiences have to other general practitioners, though they have not published them. A few years since, when small-pox was raging here, I was notified of a certain case in a house in Birkenhead; and, as public vaccinator there, I visited the house to offer its inmates the advantages of vaccination and revaccination, and thus to stamp out what might have initiated an epidemic. I found the subject of small-pox to be a tramp's child, living with its mother in the attics. With this patient I had nothing to do; but on inquiry I learned there lived in this house two other families, consisting each of a father, a mother, and half a dozen children. Of the children only one was under six months old, and accordingly the only subject for compulsory vaccination. The mother readily agreed to its being vaccinated. The other children bore marks of successful vaccination during infancy. Of subjects suitable for revaccination (that is, persons over twelve years old who had not been successfully revaccinated previously) there were only the parents. Therefore I arranged to visit the house again when the men would be at home, and on offering both husbands and wives revaccination, warning them that if they did not accept revaccination they would be attacked by variola, the women agreed and were revaccinated, the men "trusted to Providence." Father, mother, and children of each family slept in the same room, several of them together in the same bed. On that day week, as predicted, the mothers and the infant showed vaccinia, the fathers showed variola. They continued to sleep together but no more cases of small-pox occurred in this house. The original source of variola was removed to hospital. Here is an undeniable instance of contagious variola being prevented by vaccination from attacking children of various ages and adults, while it found victims sleeping in the same bed.

I am, Sir, yours truly,

P. M. BRAIDWOOD.

Liverpool, Oct. 2nd, 1882.

THE THIRLMERE WATER SCHEME.—The hearing of this case has at last terminated, and the arbitrator will, it is expected, make his award on the 30th inst. The owner of the property required by the Corporation of Manchester demands a sum variously assessed at £75,000, and £93,000, whereas the Corporation consider £20,000 a sufficient equivalent for the property.

# THE LANCET.

LONDON: SATURDAY, OCTOBER 7, 1882.

THE medical students who came up to their winter's work on Monday last will have no reason to blame the Introductory Addresses if they begin work in an unintelligent mood, or prosecute it with low motives and on wrong principles. It is true that the range of topics discarded on by the lecturers was very great, embracing everything, from the biography of CARLYLE to the peculiarities of Englishmen which explain the success of the expedition to Egypt. But even this fact does not detract, in our judgment, from the general excellence of the addresses. It is not to the point to complain of the occurrence of commonplaces and platitudes in them. Such things are not such to the young minds who are hearing them for the first time, or even, as in the case of the fourth-year student, for the fourth time. They belong to that class of truths which never pall on serious minds, and, as Dr. T. KING CHAMBERS said in his address at St. Mary's, the medical student of the present day realises that he is engaging in a serious undertaking, and is prepared to give a hearing to any respected teacher who sets forth in fairly clear terms the nature of the duties immediately or distantly before him. In no previous session that we recall has there been a better exposition of the principles of medical education than that contained in the address of Mr. MARCUS BECK, which, though delivered with singular quietness, was listened to from beginning to end with unbroken attention, or attention only broken by the appreciative laughter which was called forth by sundry very happy pieces of humour. Mr. BECK was unsanguine enough to say, in the presence of a Royal Commissioner, that we are no nearer a better examining system than we were before the investigation of the Royal Commission. We do not agree with him here; but *nous verrons*. We heartily agree with him in his suggestion that the time has come when the Apothecaries' Company might be allowed to retire from examining work, while fully admitting also with him its usefulness in times when more pretentious corporations were above their business. Not less able and complete was the address at St. Thomas's by Dr. SHARKEY, in which the foundations of medicine in anatomy and physiology were well laid, and the claim of physiology to be considered an exact science was shown to be bound up with the careful practice and use of vivisection. Dr. SHARKEY dealt iconoclastically with homœopathy, and showed that in a scientific conception of medicine the doctrine of specifics had no place. Both Mr. BECK and Dr. SHARKEY found occasion in their addresses to note the remarkable advance of surgical medicine, and to pay a well-merited tribute to PASTEUR and LISTER. Dr. HERBERT WATNEY, at St. George's, was most happy in describing the respective claims of the scientific and the practical in the studies of the medical student. Dr. CHAMBERS spoke, as he always does, in admirable English, and with equal sense. He might have had a better subject than that which he took for his

principal thesis—the eulogy of the Medical Council. But as the youngest member of that “mysterious body,” it was at least gallant in him to undertake its defence. His audience would be apt to think that he had caught some of the “mysteriousness” of the Council when he spoke of the obligation of the student to that body for the “great comfort of several examinations instead of one,” and the simplification of the curricula. This is rather bold, when we consider that there are still nineteen existing Bodies, scarcely two curricula alike, and that each Body has about three examinations. His advice to unqualified students not to put themselves into the relation of assistants to practitioners is very good as applied to those practitioners whom Dr. CHAMBERS doubtless had in his mind, who conduct a number of sham practices. The best part of his address was that in which he advocated less lecturing and more close contact between teacher and pupil. Dr. HAVILLAND HALL, after vindicating the institution of introductory lectures, enjoined thoroughness, commended attention to physical health, and summed up the duties and responsibilities of medical men by reading *in extenso* the oath of HIPPOCRATES, which is still unsurpassed after some two thousand years. The school of King's was honoured by the presence of Mr. W. H. SMITH, who described the interest he used to feel in the administration of the hospital in the days of TODD, BOWMAN, and FERGUSON, and the value of hospitals as places of education, both to the pupil and the public.

Students are thus introduced by one man or another, by one argument or another, to the great work of learning medicine, and then they are thrown on their own responsibilities, with the terrible option to be idle or industrious, to be hinderers of others or helpers, to lay the foundations of respect and reputation or otherwise. Let them count the cost. Their life now will be private, their work done in secret. Let them see to it that it is well done, so that when the examination time comes round, as it will with rapidity, the high morality of the opening lectures may be realised.

It is a remarkable fact that until quite recently our knowledge of the changes occurring in the bloodvessels of a limb after amputation has been most scanty, and the subject has been dismissed in our text-books by a bare statement that the bloodvessels of a stump are obliterated up to the next collateral branch, with in some cases a reference to the cases of aneurismal varix recorded by CADGE and AGNEW. M. VERNEUIL has studied the vessels carefully and has greatly enlarged our knowledge, and in two recent numbers of the *Revue de Chirurgie* M. SEGOND has brought forward more evidence of the same nature in a paper in which the facts upon which a judgment is to be founded are clearly stated and ably discussed. The observations have been made on limbs at very varying periods of time after amputation, and they have mainly consisted of a careful comparison of the vessels of the two limbs, which has been simplified by the previous injection of tallow through either the arch of the aorta or the abdominal aorta. The chief result obtained has been to show a marked diminution of the calibre of all the vessels in a member after amputation as a constant and early effect of the mutilation. One of the most striking cases quoted by M. SEGOND is one of amputation of the forearm, in which this mode of comparative research showed that

all the bloodvessels of the mutilated limb, even as high up as the subclavian arteries, were markedly reduced in size. In another case of old amputation of the leg the arteries were found considerably diminished in size from the end of the stump quite up to the bifurcation of the aorta. Accurate measurements showed that the loss of calibre in the arteries varied between four-fifths to one-fourth of the primitive calibre, being greatest at the extremity of the stump. Precisely similar changes have been demonstrated in the veins of these limbs, and in a case of amputation through the lower third of the thigh, the femoral vein was found to have lost three-fourths, and the external iliac vein three-fifths, of their primitive calibre. As a result of these changes in the bloodvessels there is a smaller supply of blood to these parts, and it is a familiar fact that stumps are colder than the rest of the body, though it is not so generally known that this is true of the whole of the shortened limb, and that the pulse is less strong than on the sound side, while, if re-amputation is subsequently demanded, there is less hæmorrhage than on the occasion of the primary amputation. The dissections which showed this diminished calibre of the vessels demonstrated also a wasting of the nerves, muscles, and bones of the same parts. The bones were lighter than their fellows, and were found to have undergone concentric atrophy, with in some cases marked thinning of the compact tissue. Thus, in the case of a man who had submitted to amputation through the lower third of the left forearm, the clavicle and scapula were respectively four and twelve grammes lighter on the left than the right side, and between the two arm-bones there was a similar difference of fifteen grammes in weight and seven millimetres in length. This same case illustrated well the changes in the muscles, for while the right deltoid weighed 300 grammes, the left weighed but 220 grammes; and similar differences were found in all the scapular muscles as well as those of the arm and forearm.

Several interesting questions arise in connexion with these facts. Is there any causal relation between the atrophy of the limb and the shrinking of the bloodvessels, and the attendant lessened blood-supply? Are the two events coincident? Are they both effects of one common cause? When does the shrinking of the bloodvessels commence? What is the actual force causing it? What changes are to be observed in the coats of the vessels? To some of these questions no answer can at present be given with confidence. But it appears that in no case has atrophy of the soft parts been observed without attendant lessening of the size of the bloodvessels where this has been looked for, while in a case of amputation of the leg examined after ten days by M. PONCET the femoral artery was already noticed to be smaller than its fellow of the opposite side; and although the muscles were not accurately compared, it is hardly likely that in so short a time they would have materially wasted. As the result of direct experiment upon a dog, M. SEGOND found in one case that two months after amputation of the right thigh the gluteal muscles of the two sides were of equal weight, while the right iliac and femoral arteries were visibly smaller than were the left. We may thus infer that the shrinking of the bloodvessels does not follow, but may precede, the wasting of the other tissues, and that it is a very early change in amputated

limbs. If this be so, we may with great probability ascribe the wasting of the soft parts to the lessened supply of blood received by them. The cause of this lessening of the supply of blood is not very apparent. M. SEGOND states that from experiments he has made he can affirm that when a ligature is placed on an artery in its continuity the blood-pressure on its cardiac side at once falls to a considerable extent, and he is disposed to attribute the shrinking of the bloodvessels to this fall in the local blood-pressure. The question then remains by what mechanism this fall in blood-pressure is brought about, and why does the blood-pressure fall in the iliac arteries after amputation of the leg. Again, by what histological change is a temporary contraction of the wall of a vessel converted into a permanent diminution of its calibre? At present there are no facts at hand to show the actual condition of the tissues of these shrunken vessels. M. SEGOND mentions a case of a dilated subclavian artery with very hypertrophied walls which he found in a man who had lost his arm at the shoulder. MAURICE RAYNAUD, CHAUVEL, and PIHET describe thinning of the walls of the vessels after amputation, but M. SEGOND did not observe this in any of his cases, so that we must consider this as a question awaiting solution. Much light will be thrown upon this inquiry by similar precise observations of the bloodvessels under other somewhat analogous circumstances, such, for example, as paralysed limbs, limbs with one or more stiff or useless joints, and limbs after excision of joints.

THERE may be a difficulty or an impossibility of obtaining actual uniformity in the minimum examinations of England, Ireland, and Scotland. But there should neither be difficulty nor impossibility in roughly equalising the examinations which in the three divisions of the kingdom respectively correspond to each other, and which confer the same imperial privileges. It is easy to believe, what a study of the evidence taken by the Parliamentary Committee before the Legislation of 1858 will show, that there was an understanding among the licensing authorities in the different parts of the kingdom that in sweeping away territorial limits of qualification there was to be an honourable attempt to make qualification mean the same amount of knowledge and skill. Such an understanding was of the very essence of that legislation. Practically this question has reference almost exclusively to the medical corporations of England, Ireland, and Scotland. It is not pretended that any university in the kingdom now so far forgets its own dignity as to confer its degrees on really unworthy candidates, at any rate on any large scale. The important question is this, Are the corporations in each division of the kingdom holding up the minimum examination, by which the bulk of the profession is admitted to practice. Differences in the curriculum are not so important, though this subject deserves much more attention than it has yet received, as does also the question of differences in the fees for diplomas. The difference between twenty pounds and thirty for a diploma is very much the same in London as it is in Edinburgh, and there is no good and substantial reason for any difference. The care of the Hunterian Museum involves the College in an annual expenditure, according to the accounts of the College given in the Appendix of the Blue-book, of £2360. But this

work of the College is done for the nation, and should not be paid out of the fees of candidates for the diploma. But, we repeat, questions of difference in either the fees or the curriculum, though important, are infinitely less serious than questions of difference in the substantial severity of the examinations.

The testimony of the witnesses before the committee is almost unanimous to this effect—that the examinations are not equal, that one examination is defective in one thing and another in another, and that men who are unable to pass in one place pass with considerable certainty in another. As regards the London corporations, the general impression conveyed is that the examination of the Apothecaries is less severe than that of either of the Royal Colleges. The examination of the Royal College of Physicians is very generally approved and escapes criticism the most. That of the Royal College of Surgeons of England, according to some witnesses, is objectionable in that it is uncertain, and that the candidate is too much hurried. Sir JAMES PAGET and Mr. HEATH seem to think that it is pitched fully high enough. The uncertainty of this examination and the haste of it were remarked on by the visitors of the General Medical Council. The uncertainty of it is so generally admitted by teachers and students that the College itself should make the complaint a matter of inquiry. It is only fair to the examinations of the Scotch Corporations to note that one witness at least, Mr. COOKE, said with regard to them that “they are conducted in a more uniform and reliable way as regards the results—that is, the results of the pass and pluck. I could feel much more sure that a man fairly up in his work would pass at the Scotch examinations than that the same man or even a more brilliant man would pass the English examinations.”

Nearly all the witnesses were unanimous in saying that there is a great tendency in students to go from the examinations of the English and Irish corporations to those of the Scotch corporations, and that many who failed in the English and Irish examinations came back with flying colours and a double diploma from Scotland. One explanation of English and Irish students taking the double diploma in Scotland was scarcely mentioned—namely, a vague notion that the licence of the College of Physicians entitles the holder to use the title of “Dr.” In all the history “of inform basis,” as Artemus Ward would say, there is none more shaky than this basis for an academic title. But it counts for something in the explanation of an undoubted fact. But the most serious thing is the evidence of such men as Sir JAMES PAGET, Mr. HEATH, Mr. SAMPSON GAMGEE, Dr. JACOB, and others, to the effect that men rejected at one examination pass easily at another, and that the easy examination, where everything is made pleasant, is that of the Scotch corporations. Sir JAMES PAGET says, “I have to admit reports which I am bound to believe that in the Scotch corporations they are admitted too low.” We all know Sir JAMES’S carefulness and his mastery of language. But even when pressed by Professor TURNER to mollify this conclusion, he stuck to his point, and said, “I cannot give you names, and I cannot give you numbers. If it were to be denied and disproved by numbers, I should be surprised; I cannot say more than that.” This is grave testimony. The evidence of Mr. HEATH as an examiner in the English College

of Surgeons was more direct. Mr. HEATH said distinctly that he had known many men who fail here go to Glasgow or Edinburgh and return with the double licence. Mr. GAMGEE’S evidence was equally founded on personal knowledge. He says he has several times addressed his class in confidence and said, “How is it that A. B.— went to Edinburgh or Glasgow? Can you tell me anything about what is the feeling of students on the choice of examination?” They have said, “We know very well that the Scotch colleges give the easiest examination. If a man is plucked here he can go there, and,” to use a student’s expression, “bring his ticket back.” Another serious evil brought out in the evidence before the Royal Commission is the fact that men can take part of their examination in one place and part in another, picking and choosing according to their estimate of the chance of passing. This too is an evil chiefly affecting the Scotch corporations and the Apothecaries’ Society of London. Dr. SEMPLE, asked to explain how so large a number of young men came to the Apothecaries’ Hall for their final examination who get their earlier examination elsewhere, said, “They consider our earlier examination too severe. They go to the College of Physicians of Edinburgh and get over the Chemistry somehow or other, or to the Faculty of Physicians and Surgeons of Glasgow. At any rate, they get over it somehow, and then they come back.”

It would thus seem that the Scotch corporations look as compassionately on those who dread the examinations of the Society of Apothecaries as on those who break their heads against the rocks of Lincoln’s-inn. The general impression left on the mind of the reader is that there is a complete absence of that fair approach to equality which the equal privileges enjoyed by the corporations should imply. Such aspersions on the insufficiency of the examinations of the Scotch corporations constitute a great hardship to those who hold the diplomas of these bodies, the majority of whom doubtless wish for no favour, but for a fair examination. Unless they can be refuted—and we are bound to say we see nothing in the evidence of the Scotch witnesses that does so—these diplomas must suffer seriously in public estimation, and the corporations which grant them will incur a heavy responsibility in opposing legislation which has for its object to secure that bodies professing to apply the same tests shall really do so.

THE present is essentially an age of observation and experiment. In science generally, whether we consider the pure scientist like DARWIN, or he who, like Dr. SIEMENS or Sir W. THOMSON, seems to strike the happy mean between the purely speculative and the rough-and-ready application of scientific truths to practical matters, we find that it is by experiment chiefly that advance is made, and that whatever cannot subject itself to this test must expect but scant courtesy or consideration. The remarkable success which the method has met with during this century, and more especially during the past few years, would at first sight indicate the present year of grace as a most unfitting time to question whether the rigid restriction now put upon the imagination in science is likely to help or hinder the progress of the latter. The exceeding exactness of every test seems not only to have left no room for the

poetic faculty, but has to a large extent, in the minds of many, deprived the accurate logical method of much of its value. To the deductive logician at least there is little of hope left; and if MACAULAY'S views of the Baconian method be correct, a formal adoption and study of its laws of thought can little help the man of science. Judging entirely by experience, and giving due credit to the patient toiler, it would appear that many of the most brilliant discoveries were made by some grand intuitive process which we call genius, and some of these, though most firmly believed in and accepted by all, may not even now be capable of demonstration. It was not by experiment that BLACK was enabled to declare the theory of latent heat; NEWTON could not demonstrate satisfactorily his theory of gravitation; GROVE or FARADAY could not perhaps by the modern method satisfy his hearers as to the truth of the far-reaching ideas of the conservation of force and matter; nor could Dr. TYNDALL, practical though he is, get gathered together that wonderful waistcoat-pocketful of etherial particles of which he speaks so eloquently. Such flights of fancy are now left to the poet, poetry and science being considered almost as repellant forces. In medicine we go on assiduously gathering cases as representing facts; but the observers are few who from these can boldly and correctly generalise, and timidity is felt in giving expression to views which cannot be fully proved. In the past, especially when theories were put forward by men of standing in their respective professions, there was some chance that, if incorrect, they might lead to dangerous practices; but now that criticism is so keen and tests are so rigid, there is little risk that harmful results will follow the enunciation of views that may be somewhat wild. The wings of fancy have been clipped, with doubtful advantage to science, and we might do well to more fully appreciate "the instinctive grasp which," according to Mr. RUSKIN, "the healthy imagination has of possible truth." When Sir J. PAGET says to the student, "There are such things as green roses: show the analogies between a green rose and a rickety child?" he but asks that breadth of view may be given to our studies, and exemplifies the grace which imagination has so often lent to his own discourses. While desiderating the due exercise of the higher mental powers of generalisation, and foreseeing that, without these, accumulated experience may often be little better than a rubbish heap, it would be absurd to depreciate the immense advantages to medical as well as all other science arising from the patient and profound observations of workers who have less fully developed the imaginative faculty. RUSKIN has said, "I believe there has been no true discoverer, from GALILEO and KEPLER, to DAVY, OWEN, and our own GOODSIR—the Nimrods of possible truth,—without wings"; and in this connexion SCOTT'S delighted expression on seeing the process of *singeing* muslin, by passing it rapidly over a rolling bar of red-hot iron, may be quoted: "The man that imagined this was the SHAKESPEARE of *Wabsters*."

IN consequence of the death of Dr. Silver and domestic affliction in the families of various members of the staff of the Charing-cross Hospital, no introductory ceremonies or festivities were engaged in at the opening of the School on Monday, Oct. 2nd.

## Annotations.

"No quid nimis."

### TREATMENT OF THE SICK AND WOUNDED IN EGYPT.

CERTAIN damaging statements having been made with respect to the treatment of the sick and wounded, and the administration of the Army Medical Service in Egypt, we have much pleasure in publishing the following extracts from letters by our special correspondents at Cairo and Ismailia. It will be seen that the testimony given entirely refutes the current allegations of mismanagement and failure.

Ismailia, Sept. 17th.

I have had an opportunity of seeing all the cases that have been treated antiseptically. So far, the results appear highly satisfactory, and I question if any small field hospital *dépôt* ever did more or better work in the time on the 13th than was accomplished here. Since my arrival here yesterday I have seen a large number of the cases in the hospital, also on board the *Carthage* and *Orontes*. All that could have been done at home seems to have been done; and as far as I can ascertain there is an ample supply of surgical and medical stores. We only want independent transport to be perfect. People do not understand the principles of the field hospital system; practically it is capable of going anywhere and doing all that can be reasonably required of it.

Cairo, Sept. 22nd.

At Tel-el-Kebir, on September 13th, an advanced *dépôt* (No. 3) field hospital was found at one of the entrenchments vacated by the enemy. The tents, stores, and establishment went down the Fresh Water Canal on the previous night in a flotilla of boats. On arrival the stores and *personnel* were disembarked, and the flat-bottomed horse-boats were littered with hay and supplied with planks for the easy access of the wounded. At 9.30 A.M. the first wounded European came in, and from that time until after dark the hospital was fully worked. There were twenty-five tents in all pitched. Seventeen non-commissioned officers and three of the Army Hospital Corps (exclusive of Captains Pringle and Osborne); two surgeon-majors, viz., Surgeon-Major Robinson in charge and Surgeon-Major Troup; three surgeons, Battersby, Beatty, and McGrath; Surgeons Reynolds, O'Kief, and Surgeon Sykes, I.M.D., dropping in, lent a hand at the work. The wounded were all treated antiseptically—that is, washed with carbolic solution, then the wounds themselves were dusted over with iodoform, a protector applied, and a large pad of boracic acid lint on carbolic gauze. Dr. Crookshank, House-Surgeon, King's College Hospital, undertook the preparation and arrangement of the antiseptic dressings. Two amputations were performed, and twenty bullets extracted. Two hundred Europeans were received, fed, and treated, and had opium by mouth or hypodermically, including eight officers, five of whom were seriously injured. Seven men were buried, and a grave dug, the Church of England Service being read. The Egyptian wounded received (amounting to 200) were treated as nearly as could be like the Europeans. The wounded were sent down the canal in two batches, being towed in large boats. The first batch left at noon. The boats returned at 6 P.M., but all the wounded could not be got off before 8 or 9 P.M. Their transit was admirable; easy and smooth, as if going over glass. The naval officers did splendid service, and were most untiring and obliging in their efforts. On arrival at Kassassin Lock Hospital (ten miles) the last batch of wounded were left on board the horse-boats; but hot food and drinks were supplied them, with opium and brandy, and a medical officer was left in charge. At Tel-el-Kebir Railway Station, from the 14th to the 17th September, the

following service was performed under the superintendence of Surgeon-Major Walshe:—Five large tents were pitched; 534 wounded Egyptians in all were collected; all the cases were dressed antiseptically; twenty-seven capital operations were performed; 202 of the wounded were sent to their homes; the rest were taken charge of by their own native doctors and sent by special train to Cairo. They were supplied with twenty-five tins of meat, 1000 biscuits, three bottles of brandy, and a large skin of cold water was supplied to each railway truck. The medical officers in charge were Surgeon-Major Walshe; Surgeons Rogers, Gallway, Kelsall, and Gardner (Grenadier Guards).

#### FOOD MAKES THE MAN.

SPEAKING roughly, about three-fourths, by weight, of the body of man is constituted by the fluid he consumes, and the remaining fourth by the solid material he appropriates. It is therefore no figure of speech to say that food makes the man. We might even put the case in a stronger light and affirm that man is his food. It is strictly and literally true, that "A man who drinks beer thinks beer." We make this concession to the teetotalers, and will add that good sound beer is by no means a bad thought factor, whatever may be the intellectual value of the commodity commonly sold and consumed under that name! It cannot obviously be a matter of indifference what a man eats and drinks. He is, in fact, choosing his animal and moral character when he selects his food. It is impossible for him to change his inherited nature, simply because modifications of development occupy more than an individual life, but he can help to make the particular stock to which he belongs more or less beery or fleshly or watery, and so on, by the way he feeds. We know the effect the feeding of animals has on their temper and very natures; how the dog fed on raw meat and chained up so that he cannot work off the superfluous nitrogenised material by exercise becomes a savage beast, while the same creature fed on bread-and-milk would be tame as a lamb. The same law of results is applicable to man, and every living organism is propagated "in its kind" with a physical and mental likeness. This is the underlying principle of development. Happily the truth is beginning, though slowly and imperfectly, to find a recognition it has long been denied. It is possible that in the natural desire to secure the best and purest supplies of food and drink for man we are pushing matters a little to extremes and becoming ridiculous. Utopia is a long way off, and "Hygeia" has not yet been built. It is, however, desirable that we should aim high and make the teachings of physiological science the precepts of our daily life and conduct. We may not be able to reach our ideal, but progress will be advanced by striving to make its attainment an object. "What to eat, drink, and avoid" is a rational proposition; and if some of us are becoming a little unreasonable in the attempt to solve it, at least we are on the right road, and ought to be encouraged rather than abashed by the, not unkindly, criticism our endeavours are calling forth.

#### GROCERS' LICENCES AND "LOCAL OPTION."

WE have no sympathy with the policy of Sir Wilfrid Lawson. Our professional judgment in regard to "stimulants" has been uniformly delivered in favour of moderation in their use—neither abuse nor total abstinence. We do not think society has any right to put it out of the power of its members to procure stimulating beverages because these happen to be intoxicating when taken in excess. Therefore we are opposed to "local option" as the teetotal baronet understands and would establish it. In regard, however, to the *mode* in which drink shall be supplied to the public, we think the ratepayers of a locality might be fairly consulted. At first sight it may seem that we surrender the principle for

which Sir Wilfrid Lawson contends by urging that the householders of a licensing district should have the power of prohibiting, by a vote of their majority, the issue of licences to the grocers within their locality. It may be, and is argued, that the limitation or prohibition of grocers' licences at the will of a local majority stands on precisely the same footing as the interdiction of retail licences, generally, would stand if "local option" became the law of the land. Practically the two schemes are entirely different because the refusal to allow "public-houses" for the sale of drink on draught would put it out of the power of the bulk of the population to purchase alcoholic beverages. It is with that intent "local option" is promoted! The working man could not lay in a stock wholesale, or if he did he would be exposed to the temptation of consuming it too rapidly. Sir Wilfrid Lawson and his friends distinctly mean to embarrass the consumer and cut off his supplies. We have no such purpose in recommending that the ratepayers of a district should have power to prevent the issue of grocers' licences. The refusal to allow grocers to sell bottles of brandy, gin, and sherry—which weak-minded women conceal in their boudoirs and consume in secret, to the serious detriment of their health and the destruction of their domestic happiness—would not in any way affect the liberty of the subject to drink spirits or wine with his meals. At Burnley the view of the householders has been tested, and 7776 of the citizens have decided against the issue of grocers' licences, while only 508 were in favour of their being granted within the district, and 387 were indifferent. We anticipate a similar expression of opinion elsewhere, and therefore we wish it were possible to establish "local option" in relation to these particular licences and them only.

#### SMALL-POX AND VACCINATION IN STEPNEY.

THE medical officer of health for the Board of Works district of Limehouse has recently issued his annual report for 1881, which contains some interesting facts bearing upon the prevalence of small-pox and the work of the public vaccinator within the district. The sanitary district of Limehouse appears to be co-extensive with the registration district of Stepney, such confusion of names being matter for regret. During last year 42 deaths from small-pox occurred among the residents of the district (of which but 12 were recorded within the district), 27 in the hospitals of the Metropolitan Asylum District, and 3 in the Highgate Hospital. These 42 fatal cases were 11 above the average annual number in the preceding ten years. The medical officer states that 246 cases of small-pox were reported to him during the year, 161 of which occurred in the five months ending June. Satisfaction is expressed at the zeal with which the Vaccination Acts are administered in the district, but some important figures are quoted from the report of the vaccination officer of the Stepney Union, which call for the serious attention both of the Local Government Board and of the General Register Office. The number of births registered within the district during 1881 was 2204; 1870 of these infants were successfully vaccinated, 183 died, in 16 cases vaccination was postponed or proved unsuccessful, 25 cases were removed to other unions and notice was duly sent to the respective officers, 9 remained unvaccinated, and in no fewer than 101 cases false addresses had been given by the informant at the registration, with the purpose, it may be presumed, of evading vaccination. There can be little doubt but that these 101 children, or as many of them as may be still alive, remain unvaccinated. The medical officer of health points out that, if this practice prevail to the same extent in other parts of the metropolis (which we should hope is scarcely probable), more than 6000 children annually "escape vaccination in London alone, by the simple device on the part of the

parent of giving a false address when registering the birth of a child." The inquiry is naturally suggested, how many escape vaccination by the omission to register at all? Surely such a state of things calls for thorough investigation at the hands of the central authorities for vaccination and registration.

### VASO-MOTOR PHYSIOLOGY.

THE vaso-motor effects which are produced by faradaic stimulation of the peripheral segment of the lingual nerve have been lately studied by M. Vulpian. This stimulation is well known to cause a considerable dilatation of all the vessels of the corresponding half of the tongue in the region in which this nerve is distributed. The experiment is easily performed on a dog under the influence of morphia, or which has been curarised and subjected to artificial respiration. The mucous membrane in this region, and also on the corresponding side of the frænum, becomes bright red, and a similar change may sometimes be observed in the mucous membrane of the gum on the inner surface of the lower jaw near the canine and incisor teeth. The principal vein of this part of the tongue becomes turgid, and the blood contained in it and its tributaries becomes bright in colour, resembling that of arterial blood, while there is a corresponding rise in the temperature of the part. These phenomena are produced sometimes after the lingual artery has been tied, and even after the internal and external carotid arteries of that side have been tied just above their origin, and the carotid itself has been tied in the middle of the neck. Nor are they prevented even by the ligation of the common carotid and the vertebral. The effects are equally marked after the section of the vago-sympathetic trunk, and after excision of the superior cervical ganglion. When the circulation has been definitely arrested, as by the farado-puncture of the animal's heart through the thoracic wall, the opposite half of the tongue becomes pale before that on which the lingual has been faradised. Thus the effect of the stimulation is opposed to the occurrence of the constriction of the vessels, which occurs throughout the body almost immediately after death. Another remarkable fact noted by Vulpian is that at the moment when the dilatation occurs, in consequence of the faradisation of the nerve, there is a distinct contraction of the vessels on the opposite half of the tongue. It is not merely the result of the determination of blood from one half of the tongue to the other, but is the effect of a distinct activity of the vaso-constrictor nerves, for there is a distinct darkening of the blood. This condition, however, does not last so long as the dilatation of the vessels on the faradised side. The latter may continue for ten minutes, while the former has disappeared in half a minute. This vaso-constriction appears to be reflex, for it is far less conspicuous if the vago-sympathetic trunk on that side has been previously divided. The lingual nerve seems thus to possess a certain amount of recurrent sensibility, which is manifested by this reflex action when the peripheral extremity of the divided nerves is stimulated.

### SHAM DISPENSARIES.

IN a recent number of the *Queen* appeared an article directing the attention of ladies who visit the poor to the fact that there are dispensaries and dispensaries. We have several times pointed out that by sham dispensaries a great fraud is practised on the poor, especially in the metropolis. Here it is hopeless for the applicants to distinguish between one man and another, between the qualified principal and his unqualified *locum tenens*. The word "dispensary" is greatly to blame for the extent of this fraud. It has very much the same significance to the poor as the word surgery. It may be used by the most unqualified person with nearly the same effect as a medical title, but with this advantage that

it is not included in the penal clauses of the Medical Act. It is true that the Medical Council has determined that a qualified medical man who sanctions by his name a dispensary where the patients are attended chiefly by an unqualified assistant is guilty of infamous behaviour in a professional respect, and lays himself open to be taken off the Register. But there is still need of such articles in the general press as that we allude to, and there is equal need for ladies and gentlemen too, who concern themselves with the welfare of the working and poorer classes, to study the question of their medical attendance. They should know that the connexion between cheap and unpleasant things holds especially in medicine; that the poor can for a guinea or two a year, in a provident way, in instalments, have the attendance of a respectable practitioner living near them, and that if this is not practicable and beyond their resources, the free dispensary or the Poor-law dispensary is available.

### THE INFLUENCE OF SCHOOL-WORK UPON THE HEALTH OF THE YOUNG.

AT the suggestion of the departmental authorities of Alsace-Lorraine, and under the supervision of the Imperial German Government, a commission of nine leading medical men of Mulhouse and Strasburg has been for some months occupied in the framing of an educational scheme based on the fundamental requirements of corporal and mental health. The specific object of the investigation was to see how far existing regulations are in harmony with those requirements, and to arrive at an idea of the most essential points which should be kept in view in the drawing up of further educational schemes. In their report, which has recently been issued, the opinions of the commissioners are expressed at considerable length, and stress is laid upon the fact that the principles of mental education have not partaken during late years of that progressive improvement which has characterised most branches of knowledge. Thus the greater variety of instruction which is imparted by modern education fails in many cases to accomplish its purpose, and is of advantage only to pupils of more than average capacity. It is urged that the experience of every doctor will confirm the assertion that much evil arises from school-children remaining too long in a cramped or otherwise restrained position, and from the excessive and premature strain to which the youthful brain is often subjected; while the dangers of moral and physical infection are always present. Improvements in the ventilation and the sanitary arrangements of schools, however important in themselves, are, it is urged, of comparatively little use, when the pupil is kept for too long a time every day in a combined state of bodily inactivity and mental tension. Dr. Finkelnburg's experience shows that amongst the young men who have of late years passed the educational standard which qualifies them for voluntary military service, no less than 80 per cent. were physically unsuited for the army; this proportion being nearly double that of the ordinary recruits who for temporary or permanent reasons fail to satisfy the medical officials. Between the ages of twelve and fourteen the average duration in Germany of school attendance (inclusive of the time devoted to singing and gymnastics) is thirty-two hours a week. Adding to this work the necessary home preparation of two to three hours a day, there is a diurnal task of eight hours' duration (involving for the greater portion of the time a sedentary posture) imposed upon youthful pupils at an age when fresh air and exercise are specially necessary. It is suggested that the pauses for rest should be of ten minutes' duration after every two hours of study, even if this pause comes at a comparatively short time before the close of work. The best time for holidays is stated to be from the beginning of August

to the middle of September. The necessity of clearing the class-room at intervals to allow of fresh air being freely admitted is recommended. The effect upon the visual organs of the manner in which the light is admitted, and the best style of printing for school-books, are also discussed in a practical and exhaustive manner.

#### "FEEDING LUNATICS."

IN another column we gladly print a letter from Dr. Cobbold, who, after an able and meritorious career as "assistant medical officer" in some of the largest and best conducted asylums for lunatics in this country, has been appointed medical superintendent of Earlswood, in succession to Dr. Grabham, who has been chosen as inspector of lunatics in New Zealand. Dr. Cobbold's communication is on the "feeding of lunatics," and he writes with the authority of a man who has had very extended experience in the performance of a most unpleasant duty. We respect his opinion, and are not only willing, but anxious, to give it the full weight it deserves. Nevertheless, we must be excused for adhering to the view, rather implied than expressed in our recent annotation, to the effect that it is because the task of inducing lunatics to feed naturally is left to attendants the need for forcible feeding arises. We do not blame the medical officers. When the active superintendence of some five hundred insane persons is expected of a medical man, it is no reflection on his zeal or skill that he cannot possibly fulfil the requirement. It would be absurd to say that forcible feeding is unnecessary. There are cases in which it is indispensable to use the tube. It is a very grave charge which Dr. Cobbold brings against his *confrères* when he says, "I have reason to fear that in some instances the patient's life has been sacrificed rather than the doctor's opinion." We had not the most remote suspicion that such an act of obstinacy had ever been committed or was possible. We will go farther, and, with all deference to Dr. Cobbold, affirm that we do not believe anything of the kind has ever occurred in a British asylum. If medical men err, they do so with the most earnest desire to benefit their patients; and no medical man could possibly stand by and see a patient die of starvation rather than use the tube. At the same time, we believe there is far too much feeding in asylums, simply because, although a most unpleasant and thankless operation, it is more rapidly performed than the task of inducing a perverse lunatic to eat or drink. There is no moment to spare in a large asylum. Certain cases, of course, require the tube, but these are few. It is not because they have no bad cases that some superintendents do not require to feed by force, but because they have the tact and time to exert that personal influence which no lunatic except the wholly self-engrossed can possibly resist.

#### SCARCITY OF SUBJECTS.

WE regret to hear that there is a great dearth of subjects in the various metropolitan medical schools. The proportion ready for dissection at the commencement of the session was only about one-half of the number required by the senior students, so that some time must elapse before the junior pupils can begin their dissections. Since the amendment of the Anatomy Act, which permits subjects to be kept from the summer months for the winter session, the supply has been so very good that the present scarcity has come upon both teachers and students as an unpleasant surprise. It is mainly to be attributed to the low rate of mortality during the past few months; but the increasing amount of pathological research in our workhouse infirmaries has, doubtless, had some influence in diminishing the supply to the anatomical schools.

#### UNQUALIFIED ASSISTANTS AND THEIR PRINCIPALS.

ANOTHER case of wrong diagnosis and wrong treatment by an unqualified assistant, in which the parents were deceived by all the appearances of a regular medical establishment, is recorded this week among the inquests. The case was investigated by Mr. E. Cartar at Deptford. It was that of a child aged two years and a half. The parents sent for Mr. Bowden, whose name was on the house door of No. 69, Amersham Vale. There was a red lamp over the entrance; and on the door of the consulting-room there was the name of "Dr." Scott. Mr. Scott described himself as L.S.A., and justified the title of "Dr.," when interrogated by the coroner as to its use, by saying that he was a "Doctor of Medicine of the United States of America." Dr. Billings, of the United States Army, might well decline, as he did, before the Royal Commission, to recommend the indiscriminate recognition by this country of the diplomas of the seventy-five institutions of the States which grant diplomas. We never heard before of a "Doctor of Medicine of the United States." There is a very suspicious vagueness about that title. But to return. Mr. Bowden continued to attend the child for some time, till the friends became dubious as to his diagnosis and treatment of the case, when Mr. William Kelsey was called, only to find the child past hope of recovery, and, in his belief, the victim of wrong treatment. Instead of scarlet fever, as alleged by Mr. Bowden, a post-mortem examination by Mr. Alexander Forsyth, of Greenwich, showed that death was due to pleuro-pneumonia, as had been diagnosed by Mr. Kelsey. We gather from the narrative that there was everything in this case calculated to mislead the public, as in so many other cases now accumulated: the name of a recognised medical man on the house, who, however, seems to have lived elsewhere; the assistant's name on the house too. The assistant said he had been practising nine years, which may enable the public to form some estimate of the scale of the harm done by such arrangements amongst the poor and undiscerning portions of the community. He said in his evidence that the case was reported daily to "Dr." Scott, who directed the treatment. The least satisfactory part of the investigation was the ending of it. This was most impotent. The coroner said that, although Bowden might be morally responsible, he was not criminally so. Addressing Mr. Scott, he said the jury held him "in a measure" responsible for allowing an unqualified man to prescribe in a critical case, and so the matter ended as far as the coroner and his jury are concerned. It remains to be seen what view the Medical Council will take of Mr. Scott's conduct.

#### SURGERY IN GERMANY.

IN a retrospect of the Surgical Congress which met at Berlin some months ago, the *National Zeitung* has recorded the fact that since the Franco-German war surgery has occupied a more important position in Germany than previously. This is partly attributed to the circumstance that in no country has Lister's system of treatment been more studied and appreciated. It is further stated that the replacing of portions of the human frame which may have been destroyed forms an important element of modern surgical practice in Germany. Various instances are referred to illustrative of the above remarks; amongst others the excision of a tumour from the biceps and the filling up of the cavity with a prepared piece of muscle taken from a dog. In connexion with Lister's antiseptic treatment of wounds, Germany seems to have taken up with zeal the question of a substitute for carbolic acid, and proposals have from time to time been made as to the use of salicylic acid, thyme oil, and eucalyptus oil, and more recently of naphthalene and a

preparation of common turf. Iodoform was supposed to have solved the difficulty; but despite its value in healing wounds, it occasioned such derangements in the system generally that it fell into disfavour. Dr. von Langenbeck is, however, of opinion that it is the most successful antiseptic he has yet found, but he recognises the necessity of trying to avoid the disturbances which he acknowledges it is capable of producing. Sublimate (in conjunction with a special treatment in which ordinary quartz sand is used) has been tried with success by Dr. Kümmell of Hamburg.

### DRUNK OR DYING?

ANOTHER instance in which disease was mistaken for drunkenness occurred last week in Belfast, where a man, aged forty-five, was found lying on the footpath and removed to a police cell. The next morning he was charged with being drunk, and as he then appeared to be under the influence of drink he was discharged, with an order to be summoned for another day. On being sent home, he was so unwell that a medical practitioner was sent for, who procured his admission to the Belfast Royal Hospital, where he died. A post-mortem examination showed extravasation of blood on the brain. The deceased was a man of temperate habits, and on the day he was arrested by the police had taken half a glass each of claret, port, and rum. The jury returned a verdict that death was the result of apoplexy, the jurors adding that in their opinion there had not been sufficient care bestowed upon the deceased through his not having the benefit of medical advice while in the police office. It is sometimes difficult for a medical practitioner to discriminate between alcoholic poisoning and cerebral hæmorrhage, and much more difficult for a layman; it therefore follows that where speedy recovery from apparent drunkenness does not occur, the police should invariably obtain the assistance of a medical man without delay.

### HERBALISM AND INQUESTS AT DRIFFIELD.

Two inquests here have some interest. One was demanded by the poor widow of a hostler, who obtained a dose of castor oil at a chemist's. The assistant, with a kindly view of taking the taste off, suggested mixing it with mint-water. He made a mistake and put in liquor ammonia, which caused some suffering from which the patient soon recovered, but only to die of acute tuberculosis, from which he seemed to have been suffering in the first instance. In the other case the deceased, Robert Crozier, suffered from heart disease and was prescribed for by a chemist and a herbalist. The herbalist gave a graphic account of his curriculum. Asked why he called himself a herbalist, he said, "Why, I was nineteen years in the army, and saw a good deal there, and after I took to herbs." In a free country we presume that patients must be allowed occasionally to consult chemists and herbalists. But had Crozier taken the advice of Dr. Ridpath, who detected heart disease and recommended rest, he would not have died in the harvest field, and probably now would have been alive. Freedom has its drawbacks.

### THE MEDICAL SOCIETIES.

THIS month, which in London may be said to commence the medical year, is the period for the re-assembling of the several Societies. The Obstetrical Society met on Wednesday last, the 4th inst.; the Ophthalmological Society of the United Kingdom will resume its work on Thursday the 12th, followed closely by the Clinical Society, which will commence its session on the 13th. The Medical Society will meet on Monday the 16th, and the Pathological Society on Tuesday, the 18th, whilst the Royal Medico-Chirurgical Society will open its session on Tuesday, the 25th.

### HEALTH OF THE PRIMATE.

WE understand that there is no material change in the condition of the Archbishop of Canterbury since our last report. He is free from any other suffering than that which follows from muscular weakness. There is a freer secretion of phlegm, which is now quite bronchial in character. The pulse continues quiet, 96, regular, and respiration 32. The food is relished and the sleep almost uninterrupted. The renal secretion is neutral in character, and of specific gravity, 1010; urea less than half the average quantity, but the food is not very nitrogenous. His Grace is soon tired by the small amount of business which he manages to transact. He takes great interest in the questions of the day, but his physician continues to prohibit any serious mental work.

### SMALL-POX AND QUARANTINE.

ACCORDING to the *Sydney Daily Telegraph*, the directors of the Eastern and Australian Company recently requested the medical officer of health for the City of London to advise them as to the measures which they should adopt in the event of small-pox showing itself on board a ship entering a port. Dr. Saunders has evidently convinced the Australians of the uselessness of quarantine, if we may judge by the remarks of our contemporary. They, in the first place, deal with the matter from a commercial point of view, and admit that, so far as the owners of such ships as belong to the Orient or the Peninsular and Oriental lines are concerned, the vessel might just as well founder. Then as regards those on board and the inhabitants on shore, they say they can see the sense of quarantining people, but they utterly fail to see the value of quarantining the ship, which after the removal of its crew and passengers can at once be thoroughly disinfected; and, further, they agree that such action as is necessary as regards those on board should be limited to vaccination and isolation, the isolation to be effected away from the ship, so that all chance of further infection may be put an end to. They do not, we think, attach sufficient value to the vaccination of all persons immediately after they come on board before starting for the colony, and this because such a measure would not prevent small-pox amongst any who had received the infection some eight or ten days before. This is true; but it would prevent any spread of the infection amongst the passengers even if a case broke out the day after sailing, for vaccination performed as late as two completed days after exposure to infection has been distinctly shown by the late Mr. Marson to prevent the development of small-pox.

### FIFESHIRE MEDICAL ASSOCIATION.

THIS Association of medical men practising in the county of Fife was formally inaugurated by a meeting and dinner at Cupar on the 29th ult. It is intended that the Society shall meet once a year, and exert itself more in the way of securing cordiality between the members than in scientific work. The first meeting, under the presidency of Professor J. Bell Pettigrew, of St. Andrews, was entirely successful, and he was able to offer hearty congratulations as to the numbers of members already co-operating, and to predict excellent results from these friendly meetings. The rules for the Society were agreed to, and the following gentlemen were elected as the council for the year:—Dr. Lumgair, Largo, President; Dr. Archibald, St. Andrews, Vice-President; Dr. Douglas, Cupar, Secretary; Dr. Macdonald, Cupar, Treasurer; and Dr. Constable, Messrs. Porteous and Gordon, M.B., Members of Council. The meeting was largely attended. The preliminary work has been chiefly in the hands of Dr. Douglas, and he may be congratulated on his successful efforts.

### THE COLLEGE OF PHYSICIANS IN IRELAND: CERTIFICATES IN SANITARY SCIENCE.

THIS College, following the example of the University of Dublin and the Royal University of Ireland, has recently made arrangements for granting certificates in Sanitary Science. Stated examinations will be held in January, April, July, and October. Every candidate must be a Licentiate in Medicine of the College, and must lodge a fee of five guineas, which will not be returned in case of rejection. The examination will comprise the following subjects: 1. Engineering, including hospital and house construction, sewage, drainage, ventilation, and water-supply. 2. Law: the Acts relating to Public Health; duties of health officers. 3. Etiology and prevention of disease: epidemiology, contagion, infection, hereditary influence, accommodation and conveyance of the sick, and the management of hospitals. 4. Chemistry: air, water, and food. 5. Meteorology and climatology; vital statistics. The candidate will also be examined in the analytical chemistry of air, water, and food.

### CAPTAIN SHAW'S REPORT ON THEATRES.

PART of our scheme has been adopted. Captain Shaw, C.B., the enterprising chief officer of the Fire Brigade, has been commissioned to examine and report on the state of the London theatres, and to make such suggestions as he might deem necessary. We are glad the advice we have given has been acted upon up to this point; but it remains to carry out the proposal in its entirety—namely, to place the control of the theatres, so far as their protection from fire is concerned, in Captain Shaw's hands. Put an end to the practice of dressing up supers, or at best the unskilled *employés* about the doors of places of public amusement, in the garb of firemen, and let a certain number of the trained men of the brigade be told off every night for the duty—not permanently attached to the theatres, but detailed for special duty, as soldiers are placed on guard. This would prevent anything like habitual neglect. They would be visited by their own officers at proper times, and it would be the duty of these officers to inspect all apparatus, thus securing its efficiency in case of need. The measure in progress to protect the play-going public will not, we are convinced, be complete until this scheme is adopted without reservation or abatement.

### MEDICAL ATTENDANCE AT NIGHT.

OUR contemporary, the *Globe*, comments sensibly on the absence of a provision for prompt medical attendance at nights in London, such as exists and is found to work well in Paris. We have frequently suggested such a provision. It would be liable to abuse, as every good thing is. But precautions against this could be devised. The benevolence of the medical profession is thought equal to any emergency. It is undoubtedly great, but it has been unfairly strained, and it is time for the public to understand that it has its limits.

### THE SCARLET FEVER EPIDEMIC.

THE control of the wide and subtle extension of scarlet fever in the metropolis should exercise the ingenuity of all sanitary and public authorities—and let us add, of all private families. The opinions of medical attendants should be asked not merely in regard to actual cases, but with a view to the prevention of cases. The proprietors of schools and school managers should take special steps for receiving early information of cases, and for excluding the members of infected families for a reasonable time. Where a case does occur in a family the principles of isolation and disinfection should be mastered under medical advice, and applied by

one responsible person. Where the circumstances are such as to render isolation impracticable, the case should be removed to a hospital. In the pressure of the epidemic great liberality should be extended to the London Fever Hospital, whose resources are greatly strained, but whose disposition to do good is unbounded.

### THE CHOLERA.

THE report of the appearance of cholera at Tangier has been contradicted by Her Majesty's Acting Consul-General at that port. The disease has ceased at Japan, whilst at Manilla it is still raging. The Government of the Hague has received official information of the existence of cholera at Kotta Radja, the principal settlement in Atchin. A French journal announces an outbreak of the scourge at Modane, on the French side of the Mont Cénis Tunnel. The mail-bags are consequently to be disinfected, and a medical commission has been despatched to investigate the matter.

### HOSPITAL SATURDAY FUND.

It is estimated that the collection this year will exceed that of last by £1500, and will reach £10,000. It is premature, however, to comment on the Fund, as it will be kept open till the end of October.

THE correspondent of the *Daily News*, in a telegram dated Alexandria, Oct. 3rd, states that, in spite of cooler weather, the health of the army is far from satisfactory. Since Alexandria has been again the base of operations nearly 800 sick have passed through, and 200 more are now expected. Every care is taken by the authorities to make the sick comfortable on board ship, but the discouraging part is the number who are being invalided. A later telegram, however, states that the health of the troops has undergone improvement.

AT the opening of the winter session at Owens College, the Dean of the medical school, Professor Gamage, stated that it was hoped the new medical buildings at the College would be completed by January next, so that they might expect to have them ready for the summer session of next year. When these buildings were completed, the medical school of Owens College would possess a range of laboratories and lecture-rooms which he thought would be second to those of no medical school in England.

DR. B. W. RICHARDSON, LL.D., F.R.S., having been requested by influential Liberals in Finsbury to contest the borough whenever a vacancy in its Parliamentary representation or a general election occurs, has written to the Executive Committee of the Finsbury Liberal Association to say that he shall be happy to meet them for the purpose of explaining his views as soon as his engagements will allow.

ADVICES from Cape Town, dated October 2nd, represent the small-pox in the colony as declining. The South African newspapers are, however, still much occupied with matters relating to the epidemic. Compulsory vaccination has been instituted at Natal, and the benefits of the operation are to be explained to the natives.

AT the meeting of the board of guardians of the Strand Union on the 27th ult., Dr. Rogers mentioned that he had at that time a case under his hands of erysipelas following vaccination. He followed the mother of the child to her home, and found it in so foul a state as fully, in his opinion, to account for the erysipelatous condition of the vaccinated arm.

It may be of interest to the friends of the late Dr. Lyell to learn that his funeral is to take place this day (Saturday), at Nunhead Cemetery, at 3.30 P.M. The first portion of the funeral service will be previously held at St. Andrew's, Wells-street, at 1.30 P.M.

THE typhoid epidemic at Bangor appears to exhibit no signs of abatement, notwithstanding the diversion of the water-supply from the polluted filter-beds. The fatality from the disease is, however, slight. The School Board has decided upon re-opening the elementary schools.

DR. ANDREW CLARK will deliver the Inaugural Address of the Midland Medical Society for the session 1882-83, on Wednesday, November 8th, at Birmingham.

SURGEON-MAJOR T. CAMPBELL TOLMIE is reported to be amongst the unfortunates wounded by the recent explosion and fire at the Cairo railway station.

THE medical officer of Accrington has reported to the Town Council the occurrence of twenty-seven deaths in his district from scarlet fever during September.

DR. DAVID WILLIAM CHEEVER has been appointed Professor of Surgery in Harvard Medical College.

## THE MINUTES OF EVIDENCE BEFORE THE ROYAL COMMISSION ON MEDICAL ACTS.

### THE INEQUALITY OF THE MEDICAL AND SURGICAL EXAMINATIONS.—(Concluded.)

MR. NELSON HARDY made a statement on behalf of the Medical Alliance Association, including the following remarks on modified examinations. The result of these has been known to be as follows :—

A candidate obtains the lowest possible qualification, that of the Apothecaries' Company, he then applies to the Edinburgh College of Physicians, and gets admitted to a modified examination for their licence. He then purchases a higher step, and becomes a member, and shortly after purchases another step higher, and becomes a Fellow of the said College, with really no more knowledge of his profession than that required to pass the modified examination at the Apothecaries' Hall.

DR. BARTON, *Vice-President of the Royal College of Surgeons of Ireland*, having expressed the opinion that changes of the present licensing system are requisite, replied as follows :—

4986. (*Dr. McDonnell.*) What are the chief grounds upon which you base that opinion?—I think that the want of uniformity is a loss to the public and to the profession. The exceeding difference that there is in the curriculum, in the mode of examination, and in the fees prevents it from being at all a perfect system; and I think that that is the chief direction in which the necessity for legislation or improvement exists.

4987. If I understand you rightly, you would be in favour of a more uniform system as regards fees, curricula, and examinations?—Yes, certainly; but I may add, perhaps, that whilst I think that those things warrant the answer that there ought to be changes, yet upon consideration it appears to me that greater evil would be done in getting those changes than good would be accomplished, unless the condition and status and effect of the present corporations, as they now exist, be taken into consideration, because if legislation were to take place which would destroy, or partly cripple, those corporations, I myself think that that would

do more harm in the end than leaving things just as they are would do.

*Examination of Mr. WM. STOKER, A.B.T.C.D., F.R.C.S.I., for four years examiner in the Queen's University, and having had experience in private medical teaching.*

5174. Of your own pupils educated in Ireland do many of them go to Scotland to pass?—Yes, a fair number do.

5175. Do many of them go to Scotland after having been rejected in Ireland?—Yes.

5176. From what body?—From the Queen's University.

5177. Where do they go to?—To Edinburgh.

5178. Do they prefer Edinburgh or Glasgow?—Edinburgh.

5179. Of your own pupils do a large majority of those rejected at the Queen's University go to Edinburgh to pass?—All who do not remain to re-present themselves for examination at the Queen's University.

5180. They do not, as a rule, try any of the corporations in Ireland?—No, they could not do so.

5181. Why is it that young gentlemen rejected at the Queen's University do not present themselves to our College of Surgeons or to our College of Physicians?—They have not the necessary certificates to do so.

5182. The curriculum of the Queen's University suits them in fact for Edinburgh, but would not suit them for Dublin?—Yes, that is so. The previous examination of the Queen's University is one of those accepted by Edinburgh in lieu of their own previous examination; but the College of Surgeons of Ireland will not accept any previous examination in lieu of their own. Thus a disappointed Queen's University candidate, disappointed either through having presented himself and being rejected, or disappointed from being informed that he has no chance of passing, goes to Edinburgh, where he simply has to pass the final examination of the corporations, he having already passed the previous examination at the Queen's University.

5183. I wish to understand distinctly, is it on account of the curricula rather than on account of the examination that those candidates go to Edinburgh?—Yes, that is so.

5184. You are aware, are you not, that some corporations require that the candidate before presenting himself shall sign an engagement that he has not been rejected at any place else for three months before?—I am.

5185. That regulation would lead most persons to understand that a pupil cannot be rejected in one place and very soon afterwards go and pass in another. Have you ever known any cases in which that regulation has been evaded?—I have.

5186. Can you tell the Commission how it is evaded?—A candidate, dreading the result of the examination to which he has presented himself, or to which he is about to present himself, would send in an application to the other licensing body to be admitted to examination. He says, "I am in for one examination; I am afraid I shall be rejected, and I now send in an application to another licensing body, which may make this restriction, and I state that I have not been rejected for the past three months by any licensing body."

5187. Therefore that pupil tries his hand at the first examination?—Yes.

5188. And having been rejected he goes to the other?—Yes.

5189. Do you know of your own personal knowledge of that having occurred?—Yes, clearly.

5190. (*Mr. Simon.*) You clearly have had a great deal of experience in the preparation of men for examinations, and of observing the results, and have a pretty good notion of your own of what a good and honest examiner would consider a fair and proper standard of admission to the medical profession?—Yes.

5191. Is it your experience, for I have seemed to gather this from the things you have said, but I should like explicitly to ask you, is it your experience that by certain portals men pass on to the Register with very imperfect qualifications?—It is my belief.

5192. Does that apply to both sections of the examination, that they pass their scientific examination with very imperfect scientific qualifications, and their practical examination with very imperfect practical qualifications?—It applies more markedly to the scientific examinations than it does to the practical examinations.

5193. And I believe I gather rightly that it is your experience that candidates, with advice, can dodge in particular

sections of examination, so as to get off very easily in them at particular portals?—Yes.

5212. With regard to the system, of which you have evidently had so much experience, of candidates passing, say the early examination at one board, and then going to a second board for the final examination, do you think that that system is one which leads to much abuse?—I do.

5213. Because, as the examining boards do not all have the same standard for their first examination, a candidate can pick out the easiest one, and then, having got through that, he can go on to the final examination of another board, perhaps, which gives a more reputable diploma?—You are taking things as convertible in truth which are only nominally convertible.

5214. So that a candidate may appear with the diploma of a particular body when he has not gone through the whole series of examinations of that body?—Yes, and he frequently does so.

5215. You look upon a system of that kind as not a good system?—It is open to abuses, but it is a very convenient system; and where equal things replace each other there is no objection to it in the world.

*Examination of Dr. JOHN WM. MOORE, Hon. Sec. of the Irish Medical Association.*

5434. (*Dr. McDonnell.*) Are the tests for fitness to enter the profession unequal and irregularly applied?—The Council of the Irish Medical Association are fully aware that the tests for fitness to enter the profession are so unequal and so irregularly applied that candidates rejected by one licensing body can obtain diplomas to practise from another; and that candidates who have successfully passed examinations for diplomas in medicine are rejected at examinations for diplomas in surgery, and *vice versa*. It has happened (see Lord Emsly's speech on the Lord President's Medical Act, 1858, Amendment Bill, delivered in the House of Lords on March 20th 1879) that the rejected of the King and Queen's College of Physicians have crossed the water and come back in a few weeks from Scotland as full fledged doctors or licentiates. On this point see also "Reports of the Visitors of Examinations deputed by the General Medical Council, 1873, page 213.

5618. (*Dr. B. W. Richardson.*) Has it been proved, or is it to your knowledge the fact, that any of the universities at the present time have a lower standard of examination than that which prevails elsewhere or than that standard which is a fit and fair public standard?—I do not wish to say a word bearing upon the relative positions of the universities, except this, that I am quite sure that there is great inequality.

5873. (*Dr. Struthers.*) There is a temptation, is there not, in the case of a corporation which does not exist in the case of the university?—There is, in that sense, but I do not think that the corporations are animated by such a spirit.

5874. And it has been given before us in evidence by witnesses that that temptation has led to unfortunate results?—There have been weak points in the corporations, and I confess I do not think that my friends in the Edinburgh corporations have latterly acted judiciously; it is the continuing of these half examinations that has brought all this upon them. Also, they accept one another's primary examination; if a man passes his primary at one corporation he can go up for his second at another. A man may pass the primary examination of the Apothecaries' Society here, the anatomy of which, I am quite sure, must be very poor anatomy, and then go up to the Edinburgh corporations, and that examination by the Apothecaries' Society is accepted by the Edinburgh corporations. I have here the regulations for the Edinburgh joint corporation examination, which the late Dr. Andrew Wood and I constructed more than twenty years ago, on the part of the College of Surgeons, and that regulation respecting the acceptance of other bodies' primary examinations has got into it since; I venture to say that if I had continued there that would not have got in without a protest from me; but there it is at page 10, Law 15. The result of that (though I do not say it is very common) is that when a man passes the Apothecaries' Society here, and goes up with his primary certificate, he virtually skips his anatomy and physiology. I say it is wrong of these corporations to do so, and they have brought Scotland, to a certain extent, into discredit by that. The London College of Physicians does the same, but in a better way; it accepts the examination in anatomy of any surgical body. That is safe. But if we had a conjoint examination by the corpora-

tions in each metropolis, that would be all right; they could except one another's first professional examination with entire security.

Dr. QUAIN in his evidence gave a history of the conjoint scheme in the Medical Council and put in the following important extract from the Report of Committee on Professional Education, 1869, which was afterwards adopted by the Council:

"One of the great evils at the present moment is the inequality of the examinations for the licence. This inequality of the test of efficiency is the more unfortunate, as every licence confers an equality in the right to practise everywhere. The easy examination of one licensing body tends to depress the standard of the examination in all the rest. Visitations of examinations doubtless partly remedy this state of things, but to completely remove it a bolder course is necessary. The time has now arrived when, leaving to the universities and corporations full liberty to deal as they please with their honorary distinctions and degrees, the Medical Council should endeavour to effect such combinations of the licensing bodies included in Schedule A as may form a conjoint examining board for each division of the kingdom, before which every person who desired a licence to practise should appear, and by which he should be examined on all subjects. Any higher degrees he may wish to take should come after, and should be optional.

"This plan is one which the Council has often approached, and has recommended in principle.

"We feel assured that the examinations for licence will never be made satisfactory without it, and therefore that it is for the public good to enforce it without delay."

## VITAL STATISTICS.

### HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns, 5717 births and 3344 deaths were registered during the week ending the 30th ult. The annual death-rate in these towns, which had been equal to 20.0 and 20.8 per 1000 in the two preceding weeks, declined again last week to 20.6. The lowest rates in these towns were 13.7 in Derby, 14.4 in Bristol, and 14.8 in Nottingham. The rates in the other towns ranged upwards to 26.1 in Salford, 27.0 in Manchester, 30.7 in Sunderland, and 32.6 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns were 536, showing a further decline from recent weekly numbers; 162 resulted from diarrhoea, 130 from scarlet fever, 75 from whooping-cough, 73 from "fever" (principally enteric), 49 from measles, 37 from diphtheria, and 10 from small-pox. No death from any of these diseases occurred in Plymouth, whereas they caused the highest death-rates in Preston and Cardiff. Diarrhoea caused the highest death-rates in Hull and Preston; scarlet fever in Sheffield, Leicester, and Cardiff; whooping-cough in Halifax and Preston; measles in Hull and Sunderland, and "fever" in Birkenhead, Liverpool, and Leeds. Of the 37 deaths from diphtheria in the twenty-eight towns, 28 occurred in London, and 2 both in Liverpool and Leeds. Small-pox caused 10 deaths in London and its outer ring of suburban districts and one each in Birmingham, Leeds, and Newcastle-on-Tyne. The number of small-pox patients in the metropolitan asylum hospitals, which had steadily declined from 114 to 79 in the four preceding weeks, were 80 on Saturday last; 17 new cases of small-pox were admitted to these hospitals during last week, against 9, 10, and 13 in the three previous weeks. The deaths referred to diseases of the respiratory organs in London, which had been 178, 193, and 263 in the three previous weeks, further rose to 300 last week, and exceeded the corrected weekly average by 87. The causes of 66, or 2.0 per cent., of the deaths in the twenty-eight towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Brighton, Portsmouth, and in eight other smaller towns; whereas the proportions of uncertified deaths were largest in Preston and Sheffield.

### HEALTH OF SCOTCH TOWNS.

The annual death-rate in the eight Scotch towns, which had been equal to 20.9 and 18.1 per 1000 in the two preceding weeks, rose to 21.0 in the week ending the 30th ult., and exceeded by 0.4 the mean rate during the week

in the twenty-eight large English towns. The deaths referred to the principal zymotic diseases in these Scotch towns, which had been 103 and 83 in the two previous weeks, rose to 117 last week; they included 36 from diarrhoea, 23 from diphtheria, 22 from scarlet fever, 17 from whooping-cough, 13 from "fever," 6 from measles, and not one from small-pox. The death-rate from these principal zymotic diseases averaged 5 per 1000 in the eight towns, and exceeded by 1·7, or more than a third, the rate from the same diseases in the large English towns. The highest zymotic death-rates occurred last week in Perth and Leith. The 34 deaths attributed to diarrhoea showed an increase of 2 upon those in the previous week, and were equal to a rate considerably exceeding that which prevailed from the same cause in the English towns. The 17 fatal cases of whooping-cough, included 11 in Glasgow and 3 in Paisley. The deaths from diphtheria, which had been 12 and 9 in the two previous weeks, rose to 23 last week; 15 occurred in Glasgow, 3 in Aberdeen, and 2 in Greenock. The 22 fatal cases of scarlet fever also showed a marked increase upon recently weekly numbers, and included 12 in Glasgow, 4 in Dundee, and 4 in Edinburgh and Leith. The 13 deaths referred to "fever" showed a further slight increase upon the numbers in the two previous weeks, including 7 in Glasgow, and 2 both in Edinburgh and Perth. Two fatal cases of measles occurred in Edinburgh, and 2 in Dundee. The deaths referred to acute diseases of the lungs in the eight towns, which had been but 61, 70, and 72 in the three preceding weeks, further rose to 102 last week, and exceeded by 19 the number attributed to the same diseases in the corresponding week of last year.

## HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 25·8 and 26·1 per 1000 in the two preceding weeks, declined to 23·7 in the week ending the 30th ult. During the thirteen weeks ending last Saturday the death-rate in this city averaged 23·1 per 1000, against 18·6 in London and 17·8 in Edinburgh. The 158 deaths in Dublin last week showed a decline of 16 upon the number in the previous week; they included 8 which were referred to diarrhoea, 2 to whooping-cough, 2 to diphtheria, one each to measles, scarlet fever, and "fever," and not one to small-pox. Thus 15 deaths resulted from these principal zymotic diseases, against 28 and 15 in the two preceding weeks; they were equal to an annual rate of 2·2 per 1000, while the rate from the same diseases was 2·8 in London and 3·4 in Edinburgh. The fatal cases of diarrhoea, which had declined from 19 to 10 in the four previous weeks, further fell to 8 last week, and were equal to a rate considerably lower than that which prevailed from the same cause in Edinburgh. The deaths referred to whooping-cough and "fever" showed a decline from recent weekly numbers, while those from diphtheria were more numerous. The deaths of infants were fewer than those of the previous week, while the deaths of elderly persons showed an increase. The causes of 30, or 19 per cent., of the deaths registered during the week were not certified.

## THE SERVICES.

ARMY MEDICAL DEPARTMENT.—Surgeon-Major Robert Batho has been granted retired pay, with the honorary rank of Brigade Surgeon.

INDIA OFFICE.—The Queen has approved of the retirement of Surgeon-Majors John Berry White, Thomas Edmondstone Charles, M.D., of the Bengal Army, and George Edward Whitton, of the Madras Army.

BREVET.—To be Deputy Surgeon General: Brigade Surgeon David Boyes Smith, M.D., of the Bengal Army.

ARTILLERY VOLUNTEERS.—1st Fife-shire: William Hessman Goodenough, Gent., to be Acting Surgeon.

RIFLE VOLUNTEERS.—2nd Gloucestershire: Peter Buchanan, Gent., M.B., to be Acting Surgeon.

ADMIRALTY.—Staff Surgeon John Mulvany has been promoted to the rank of Fleet Surgeon in Her Majesty's Fleet, with seniority of 22nd ult.

The following appointments have been made:—Fleet Surgeon Henry Hadlow, to the *President* (additional); Fleet Surgeon John Mulvany, to the *Constance* (commissioned); Staff Surgeon Alexander Mitchell, to the *Dragon*; Surgeon

Charles James, to the *Royal Adelaide*, vice William E. Bennett; Staff Surgeon Robert J. M'Morris, to the *Crocodile*; Staff Surgeon George Kell, to Portsmouth Dockyard, vice Mulvany; Staff Surgeon Richard J. Coppinger, M.D., to the *Vernon*, vice Kell; Staff Surgeon John R. Burke, to the *Belleisle*, vice Fisher; and Patrick C. Gorham, to be Surgeon and Agent at Roundstone, county Galway; Staff Surgeon Edward W. Doyle to the *Hercules*, vice Staff Surgeon Gorham.

## Correspondence.

"Audi alteram partem."

## THE BOGUS FELLOWSHIPS OF THE EDINBURGH COLLEGE OF SURGEONS.

To the Editor of THE LANCET.

SIR,—In your leading article for September 30th, I notice some severe yet well-merited strictures on the sale of Fellowships by the Edinburgh College of Surgeons. As one of the minority of its Fellows who regard the present system as a crying abuse, permit me not only to endorse your opinions in the article above referred to, but further to add to them other revelations of a state of matters still more anomalous.

Before inquiring into the why and the wherefore of the persistence of such an obsolete system, it may not be uninteresting to adduce one or two additional facts in corroboration of the statements advanced in your article. In so doing, I shall strictly confine myself within the limits of my own personal experience.

When I was a very young Fellow, and had still to learn the manners and customs of my corporation relative to the admission of all sorts and conditions of men, I was surprised to find one day among the list of candidates the name of a gentleman who, to my certain knowledge, after being rejected again and again at the M.B. Examinations in the University of Edinburgh, had finally taken refuge in the arms of the College, whose licence, after sundry little accidents, he had at last managed to obtain. Acting on strong conviction as to the unsuitability of this candidature, I endeavoured, so far as in me lay, to prevent his election; but at the final ballot, I was informed that as the name had been approved by the President's Council, its rejection by the College would be a thing unheard of. The gentleman in question was duly elected.

So much for an old instance; now for a modern one. Not long ago I received a letter from a very young practitioner with whom I had the slightest possible acquaintance, asking me as a mere matter of form to propose for the Fellowship a friend of his own, whom I had never seen or heard of, and who did not even hold the licence of the Edinburgh College. I hunted up the name of the aspirant in the Medical Directory, and finding his qualifications to be of the most ordinary description, I felt constrained to return a civil refusal. To my astonishment, at the very next meeting of the College, this gentleman, duly proposed and seconded, was brought forward, and balloted for in the ordinary course after approval by the Council, his election being, I need scarcely say, a foregone conclusion; indeed, since I became a Fellow, I have never known a single instance of rejection by the College after approval by the President's Council. In many cases a sufficient number of black balls to exclude some worthless candidate might easily have been mustered, but for the "bated breath and whispering humbleness" with which the opinion of Council is invariably received. It may be asked, Why does not the general body of Fellows on the roll of attendance resist such attempts at dictation? Many good and sufficient answers might be returned to this query.

In the first place the would-be reformers are in a minority—a large minority it is true, but still a minority. They have little cohesion or organisation, and are for the most part juniors, that is to say, men between thirty and forty years of age. Many of them are actuated by an absurd awe of their seniors, altogether unintelligible to Englishmen unacquainted with the system of cliques and coteries whose favour is the shortest cut to professional success in Edinburgh. They are confronted too by a compact body of seniors, who

treat their opinions with such supercilious hauteur, that the more weak-minded begin at last to entertain serious doubts as to whether or no they have any right or title to form opinions for themselves at all.

Secondly, the Council virtually possesses the power of self-election. Every year the retiring Council prepares a list of its successors, and of the examiners for the ensuing year; and these nominations can only be overturned by a most troublesome and humiliating personal canvass, on the part of any aspirant to these important positions. Men who from pride or delicacy hesitate to encounter the numberless impertinences to which such a procedure exposes them are left hopelessly in the background.

A place in the Council, or on the Board of Examiners, thus becomes a distinction reserved only for the favoured few, who in the vast majority of instances are men whose qualification lies in the extent of their local influence. This abuse is perhaps most glaring in the case of the examinerships. Specially qualified persons are passed over; an examiner once appointed is virtually installed in his office for life. The character of the examinations falls behind the standard of the day; the same questions are set over and over again, so that some of the "grinders" know almost all of them by heart. Good-for-nothing students flock to the Edinburgh Colleges from all parts of the kingdom, and pass; and thus a great school is brought into disrepute in the teeth of its own disgusted lecturers, many of whom have no chance of an examinership for years to come. In the meantime general practitioners of no special acquirements examine in the subjects to which such non-examining lecturers are devoting a lifetime of unrewarded study. By one of these gentlemen a student was, not long ago, asked at the examination-table how much fibrine was contained in the blood circulating in the vessels during life? Surely such a system of examination is an anachronism.

Were the Edinburgh Fellowship to be granted after examination, the examiners, unless ludicrously incompetent, would of necessity require to be drafted largely from the junior Fellows, many of whom are graduates of the University of Edinburgh with the highest honours, and lecturers licensed by the College itself. Perhaps this consideration may have some bearing on the desperate reluctance evinced by the seniors to adopt a change which would otherwise appear little short of a self-evident necessity.

These things, Sir, call imperatively for reform. Were they as well known to the profession at large as they are within the confines of the northern metropolis, their lease of life would, it is to be hoped, be short. In widespread publicity alone lies the chance of their early abolition; and the thanks of all true friends of the Edinburgh College of Surgeons are due to you for the strictures you have already passed upon the action of a certain section of its governing body. These, however, are as nothing compared to the many more which might still be made,

I am, Sir, your obedient servant,

ONE OF THE MINORITY.

October, 1882.

To the Editor of THE LANCET.

SIR,—I am sure that the profession, as a whole, will support you in your exposure of the Edinburgh "Bogus" Fellowship. It is most unfair to those who have worked harder than their brother students in order to gain the Fellowship of the Royal College of Surgeons of England, to find that others hold the same title, "F.R.C.S.," without work, and by payment of a fee, coupled with the presentation of a minimum qualification in surgery. I notice that few fellows of the Edinburgh College add "Edin." to the title, which would give the public a better chance of distinguishing them from those of the London College. That it is a qualification is undoubted, as many appointments are advertised where the Fellowship of the College of Surgeons of England or Scotland is mentioned as a *sine quâ non*. I remember when I was an undergraduate of a certain university in Scotland, two men failing, after repeated efforts, to pass the first professional examination there. Like the friends of the Claimant, they had "more money than brains," so after repeated trials, in which their ignorance of the usual details of the subjects of examination was shown each time more distinctly, they were advised by their teachers to give up all thoughts of entering the profession. They were, however, not to be daunted, and being

"rare plucky ones," they reminded their friends that there was no one-portal system to medical diplomas. They went to Edinburgh, got the "double qualification," and after a time blossomed out into the higher (!) dignities of—the one, F.R.C.S.E., the other, M.R.C.P.E. (of course with the addition of the title "Dr." on his card). Whether these gentlemen are alive or not now I know not, and would rather not know. The circumstances were much commented on at the time by those who had known them, and many others, who were "wasters," intended to follow their examples. I do not mean to say that there are not excellent men who hold this title, and it is for their sakes that the honour of the College should not be prostituted for the sake of gold. Let the Fellowship be looked upon once more as a distinction; let there be a further examination for it, severe in its nature, and then men would willingly come forward and try to obtain it; but as long as it is to be bought it will be looked upon with some suspicion, and the minority of those holding it as a title of real honour will be few and far between. I see by the new regulations of the Royal College of Physicians of Edinburgh that the election to the membership is abolished, and that candidates now are required to be examined in medicine, pathology, and midwifery. This is a right move, and one which I hope the sister College of Surgeons will follow shortly, and do away with the idea that the fellowship is simply a question of £ s. d.—I am, Sir, yours faithfully,

Oct. 2nd, 1882.

M.B.

### "FEEDING LUNATICS."

To the Editor of THE LANCET.

SIR,—Lest your annotation on this subject in to-day's LANCET should lead to the belief that the forcible feeding of lunatics is an unnecessary form of coercion, I venture to offer a few remarks in reply.

This operation, when necessary, devolves in almost all asylums upon the assistant medical officer. As I held that office for more than eight years in three of the largest lunatic asylums in this country (over 5000 patients having at one time or another during that period been under my care), I have had considerable experience in the matter. The operation of feeding through the œsophageal tube is certainly not without its difficulties, but these may, I believe, be always overcome—indeed, I never once failed to complete the operation satisfactorily. I have never seen the procedure do harm to any patient; but, on the other hand, I am perfectly certain that several patients who have since recovered and resumed their positions in the outer world would have died if they had not been forcibly fed with the tube.

It would, of course, be inexcusable to feed any patient through the stomach-tube until every other means of inducing him to take nourishment had failed. Such a patient should always be placed in a ward where the best nursing is available. The attendants should be impressed, both by precept and example, with the necessity of inducing their patient, either by coaxing or by judicious firmness, to take his food in a natural manner. Many attendants are very successful in this respect, but even the best occasionally fail. It is then the province of the doctor to intervene. The great influence and prestige which he ought always to possess and maintain with his patients will frequently enable him to prove successful in persuading a patient to take proffered food after all the efforts of the attendants have proved unavailing. When the patient's chief reason for refusal is mere obstinacy, it is often sufficient for the medical man to produce his feeding apparatus and explain kindly but firmly to the patient that unless he drinks the fluid food prepared, the tube will be passed down his throat into his stomach, with certain discomfort to himself.

There will always, however, be a certain number of patients who, owing to delusion, suicidal intent, or some other cause, can neither be charmed nor threatened by the above-mentioned, or any other methods, into taking the food offered to them, and who will not swallow what is placed in their mouths; these must consequently be fed by means of the tube. I am quite aware that it is the boast of some medical superintendents that they have never found it necessary to feed a patient in this manner, but I have reason to fear that in some instances the patient's life has been sacrificed rather than the doctor's opinion. I

can quite believe that in an asylum containing only 100 or 200 patients it might often happen that for many years at a time no case would require to be forcibly fed; but in our largest lunatic asylums, which contain from 1000 to 2200 patients in each, it rarely happens that many weeks pass without some patient requiring this treatment. Asylum medical officers can have no reason for performing this operation with unnecessary frequency, as it is by no means a pleasant duty, and brings neither pecuniary gain nor professional *κῶδος*. Instances are on record in which patients have been thus fed daily for many months, and even years; but it is my belief that when a patient has acquired an undesirable taste for being fed in this way, his trouble-some habit may almost always be successfully combated by the exercise of a little tact on the part of the medical attendant. I have no experience of any case in which the necessity for forcible feeding has existed for longer than three or four weeks at a time.

It is no part of my object in this letter to describe the best methods of forcible feeding, but merely to affirm that the operation is sometimes an absolute necessity for the saving of life, and that the lives saved are in a considerable proportion of cases those of patients who ultimately recover and return to their homes. If there are abuses in asylums (and what human institutions are perfect?), by all means let us have them exposed and remedied; but at the present time, when the public mind is, causelessly, as I believe, somewhat uneasy upon the subject of the care and treatment of the insane, it is most undesirable that the idea should become general that insane persons are needlessly subjected to the discomfort of having tubes passed into their stomachs, even though the object be to supply them with the food necessary to their sustenance and recovery.

I am, Sir, your obedient servant,

CHAS. S. W. COBBOLD, M.D.,  
Sept. 23rd, 1882. Medical Superintendent, Earlswood Asylum.

#### "A SIMPLE OPERATION FOR VARICOCELE."

To the Editor of THE LANCET.

SIR,—In to-day's number of THE LANCET Mr. A. Barker reports three cases of varicocele under the above heading. It may perhaps be of interest to him and others who intend to try this method to know that I have also had a case in which I performed the operation in the same way as Mr. Barker, and with an equally good result. The case was a man aged fifty years, a miner, who was admitted under my care into the York County Hospital in April last, suffering from a large varicocele on the left side. I performed the operation in almost identically the same way as Mr. Barker, encircling the veins with a piece of Chinese silk (which had previously been boiled for half an hour in a ten per cent. solution, and afterwards left to soak for some hours in a twenty per cent. solution of carbolic acid); after tying, the ends of the silk were cut short, and dropped into the wound, which was closed up over them. The wound healed in a few days with scarcely any suppuration. I kept the man in the hospital for a fortnight after everything seemed quite well, and when he went out there was no sign of inflammation at all about the wound, which was soundly healed, and all that could be detected was a small nodule on the seat of ligature.

I am, Sir, yours faithfully,  
W. H. JALLAND, F.R.C.S.  
York, Sept. 30th, 1882.

#### THE QUEEN'S UNIVERSITY DEGREES.

To the Editor of THE LANCET.

SIR,—Your correspondent "J. W. M." takes exception in last week's LANCET, to a statement made by me before the Royal Commission on the Medical Acts to the effect that "A student attending a Queen's College may obtain all the lectures necessary for a Queen's University Degree (or Scotch double diploma), in two years," which, he says, "is not a fact." That the statement is accurately true may be proved by anyone who pleases to examine the regulations of the Queen's University, published in your Student's number for 1881 and previous years. Two courses of lectures, at most, were required by the University in any subject, and these were readily obtained in two years. Indeed, I have

known many students who—having put in, in a Queen's College, the essential two courses of medical, and two courses of non-medical lectures, *all in one Winter Session*—have taken all the remainder of their curriculum in Dublin, and have possessed their M.D. Q.U.I., and L.R.C.S. and C.P. Edin., long before the lapse of the statutory four years. It is true that the Q.U.I. required twenty-four months' hospital, so that a student commencing in November of any year could not theoretically complete his hospital curriculum until two years and three months had elapsed, but that difficulty was always easily adjusted with the hospital authorities. Therefore, it is quite true, as I stated, that a student could (and many did) complete his entire curriculum for the M.D. Q.U.I. and Scotch Double Diploma in a couple of months over two years, and that a great number of Irish students, therefore, took these qualifications in preference to the M.B. Dublin University, or L.R.C.S.I. or L.K.Q.C.P.I., which would have cost them an additional year's work and fees.

I am, Sir, yours, &c.,

ARCHIBALD H. JACOB, M.D. Dub., F.R.C.S.I.  
Dublin, Oct. 4th, 1882.

#### DISTRIBUTION OF THE REPORTS OF THE LOCAL GOVERNMENT BOARD.

To the Editor of THE LANCET.

SIR,—I have this day forwarded to the President of the Local Government Board a memorial from the North-Western and Yorkshire Associations of Medical Officers of Health, of which the enclosed is a copy.

I am, Sir, yours truly,

Manchester, Oct. 4th, 1882. FRANCIS VACHER.

To the Right Hon. J. G. Dodson, M.P., President of the Local Government Board.

The memorial of the North-Western and Yorkshire Associations of Medical Officers of Health.

Respectfully sheweth,—That your memorialists are a body of Medical Officers of Health practising in the counties of Lancaster, Chester, Derby, and York. That your memorialists having been from time to time instructed and informed by the annual reports of the medical officer of your Honourable Board, and forming a high estimate of the importance of the topics discussed in the said reports, and having experienced difficulty in obtaining copies of the same owing to the small number printed, humbly pray that your Honourable Board will order that a copy of the said report, with appendices, may henceforth annually, as issued, be presented to every medical officer of health whose appointment shall have the sanction of your Honourable Board. And your memorialists will ever pray, &c.

(Signed on behalf of the North-Western Association of Medical Officers of Health.)

WM. HUGH HUGHES, President.

FRANCIS VACHER, Hon. Sec.

(Signed on behalf of the Yorkshire Association of Medical Officers of Health.)

S. W. NORTH, President.

J. MITCHELL WILSON, M.B., Hon. Sec.

100, King-street, Manchester, Oct. 4th, 1882.

#### NEWCASTLE-ON-TYNE.

(From our own Correspondent.)

AT the sanitary meetings on Thursday, the 23th ult., the following were read and discussed:—Address by Professor Robinson, C.E., Vice-president of the Section, in which he strongly pointed out the necessity of proper training for inspectors. W. Eassie, C.E.: "The Desirability or otherwise of providing Town and Country Houses with Grease Intercepting Chambers in Scullery Sinks." J. Lemon, M.I.C.E.: "The Separate System of Drainage." E.C. Robins, M.I.C.E.: "On the Original Experiments of Dr. Renk of Munich, with Sewer Gas, and the Mode of its Exclusion from Dwelling Houses." W. G. Laws: "Sewer Ventilation." John Price: "Industrial Dwellings." W. Eassie, C.E.: "On the Sanitary Needs of Town and Country

Houses." In the evening a lecture was delivered to the Congress, "On the Food and Energy of Man," by Professor F. S. B. De Chaumont, M.D., F.R.S., in which he advocated variety as advantageous, and, indeed, thought that tobacco and alcohol might often be used with benefit.

On Friday the following was the order of business:—Address by Arthur Mitchell, M.A., M.D., F.R.S. H. C. Bartlett, F.C.S.: "On the Influence of Minute Suspended Matter on Health—its Detection, Collection, and Examination." The Hon. F. A. Rollo Russell: "The Improvement of Climate with Slight Elevation." R. Carr Ellison, J.P.: "The Influence of the Purity or Impurity of the External Atmosphere on Public Health, Public Comfort, and on the Domestic Habits of the People." R. B. Grantham, M.I.C.E.: "On the Establishment of a Library for a Special Branch of Sanitary Information at Newcastle." At 5 P.M. the closing general meeting of the Congress; and at 7 P.M. the public dinner at our Assembly-rooms, which was a spirited and lively entertainment—a great contrast to Tuesday's luncheon, which was rather flat and forced, rather like a wedding-breakfast *minus* the bride and bridesmaids, and with scarcely an opportunity of "toasting" the ladies, or of giving the bachelor members a chance of descanting on "youth and beauty," the fair sex being "only conspicuous by their absence." It has been decided to hold the next Congress at Glasgow. On Saturday His Grace the Duke of Northumberland kindly invited the members of the Institute and the associates of the Congress, to the number of 300, and entertained them to luncheon at his historical seat, Alnwick Castle. This was arranged with the princely munificence customary to the house of "the Percies." Other excursions to points of interest in the vicinity took place, and the week's business may be said to have finished up with a lecture to the working classes by Dr. W. B. Richardson, F.R.S. Now that the *fanfare* of the Congress has subsided, and the echoes of congratulations from many sanitary voices have died away, we may ask ourselves, What have we gained? Well, the question is not so easily answered. Many of the papers read reached a high scientific standard; others, again, might be described as "medium quality"; while a few possessed an ephemeral character, and would soon be forgotten. For some reason, or for no reason, the intelligent classes of our citizens appeared to take very little interest in it, as judged by their attendance at the discussions, which might as a rule be characterised as tame. As a set-off, it is only fair to acknowledge the very full reports of the proceedings given by our local newspapers. In the discussion on Captain Hildyard's paper, "The Influence which Medical Men might exercise on Sanitary Progress in their Private Practice," our medical officer of health said "he did not think that medical men took a sufficient interest in sanitation," and instanced (in support of this curious view) the petition signed by forty-six medical men of Newcastle, "who at the time they put their names to the petition did not know what was in the Bill." On the other hand, Captain Galton, the President of the Congress, held that "medical men had been the originators of all sanitary improvements," while Mr. T. P. Barkas said that "at the time the petition was signed, the compulsory notification of diseases clauses remained in the Bill." It is felt here that our usually intelligent health officer did not display this quality of mind on this occasion. The forty-six medical men knew perfectly well what they were signing. In the Town Improvement Bill, which was an application for money and for power to carry out various improvements, these compulsory clauses were involved or "smuggled" into the legislature. The citizens were denied a public meeting where our profession might, as ordinary members of the community, have discussed these clauses. So a manifest attempt is made to keep our profession in ignorance and to stifle public opinion, and then it is blamed for what it could not help. Our health officer is not a practising medical man, and hence he can only see one side of this coercive sanitarian question. I mean the official side; for as regards the domestic and medical aspect he is evidently colour blind. Has anyone in this Congress suggested, say a few years' experience in general practice, as one of the qualifications for a medical officer of health? if not, it would be highly desirable. It must be remembered that these forty-six medical men who have been so rashly and publicly charged with ignorance and obstruction, will represent about one-half of the practising men of our city, of all grades, too, as to age and experience. Does our medical officer of health consider

when he gets on his sanitary stilts that he embodies the sanitary wisdom of the North of England? and that the profession here is to sit still in awe like the scholars of Goldsmith's pedagogue, when—

"Still they gazed, and still the wonder grew,  
That one small head could carry all he knew."

The magnificent Marine Exhibition at Tynemouth, alluded to in my last letter, still continues to draw its tens of thousands daily. I am glad to see that it is to remain open until Oct. 14th, and that the railway company has given increased travelling facilities in visiting it. Professor Corfield, in presenting the prizes at the Sanitary Exhibition here, which is also to remain open for a longer period, said it was an exceedingly good and successful one. I have only space here to mention some of the most successful and interesting exhibits—viz., Messrs. Mather and Armstrong, Newcastle, for Siemens' patent regenerative gas burners. Messrs. Hayward, Tyler, and Co., for full-flush valveless closets. La Société Hygiène Française, Paris, for their exhibits of books on health. Messrs. Brady and Martin, Newcastle, for scientific instruments. This firm has a well-furnished stand of articles of domestic and medical interest, including the popular Montserrat lime-juice of Messrs. Evans, of Liverpool. This juice has the confidence of the profession here, and is largely prescribed for domestic and marine consumption. Messrs. Mawson and Swan have also a stand characteristic of the scientific energy and taste of this eminent firm, making a strong point of their disinfecting exhibits, and issuing very useful "Notes on Hygiene." Not the least interesting exhibit to a medical visitor is that of Messrs. Irvine & Co., Mustard Manufacturers, Gateshead, established 1791. Their stand shows the processes in the manufacture—viz., the brown seed whole, its crushed state, its pulverised state, and lastly, as the finished article, sifted into an impalpable powder. Irvine's mustard has unmistakable qualities as a counter-irritant, while as a condiment their "Durham mustard" is in high favour here from its purity and flavour. The winter session of the College of Medicine here was opened yesterday with great *éclat*. Dr. Gibson, in the absence of Dr. Heath, presided, while our Mayor, in the absence of the Bishop of Newcastle, presented the prizes. Dr. W. B. Richardson was present, and made some very pointed and happy remarks. Dr. Thomas Oliver, physician to our infirmary, read the inaugural address "On Medicine, its Progressiveness and Relation to Civilisation." I need make no comment on this address as it will doubtless be noticed under its proper heading in THE LANCET, but I may say it met with well-merited applause. This College, while it has increased in quantity as to students, I fear has deteriorated as to "quality." The behaviour of the young "gentlemen" was simply outrageous. Making every allowance for the high flow of spirits natural to the student, I have sat on many benches in many countries and never witnessed anything like the disorder of yesterday's proceedings. Would not a *conversazione* another time have a more soothing effect on these turbulent tyros?

Newcastle-on-Tyne, Oct. 3rd, 1882.

## EDINBURGH.

(From our own Correspondent.)

THE VACANT ASSISTANT-SURGEONCY TO THE ROYAL INFIRMARY. — THE VACANT PATHOLOGISTSHIP TO THE ROYAL INFIRMARY.—THE NEW UNIVERSITY BUILDINGS.

AUGUST and September are essentially holiday months here, both patients and doctors being out of town and nothing of medical interest occurring. This year the usual monotony has been somewhat interrupted by the contest for the assistant-surgeonship to the Royal Infirmary, which is still being actively carried on. The vacancy, which is occasioned by the promotion of Dr. Miller to the full surgeoncy, will be filled up on the 16th. Drs. Caird, Cathcart, Cotterill, and Macgillivray are the candidates, and so far as I can learn Drs. Cotterill and Macgillivray are generally considered to have the best chance.

On the same date (Oct. 16th) the pathologist to the Royal Infirmary will be appointed in the place of Dr. Hamilton, the recently elected Erasmus Wilson Professor of Pathology in the University of Aberdeen. Dr. Hamil-

ton's loss is no small one to Edinburgh, and his successor will find it no easy task to maintain the pathological department of the infirmary in its present high state of efficiency. The candidates are Drs. Byrom Bramwell, Alex. Bruce, and Woodhead.

The new University Buildings are now so far completed that the whole of the medical classes, with the exception of materia medica, medical jurisprudence, and chemistry will be carried on there during the forthcoming session. It is difficult without a personal visit to form an adequate conception of these palatial buildings, but the reader will gain some idea of the facilities for teaching and original work which they afford by perusing the following description, which appeared a day or two ago in the pages of the *Scotsman* :—

"With the exception of the classes of materia medica, of medical jurisprudence, and of chemistry, which are to be located in the Tiviot row, or north and west sides of the north quadrangle, the several departments will be ready for occupation in the ensuing month. As matters at present stand, there would seem to be no hope of having the other departments ready for occupation for at least eighteen months or two years to come. Only that portion of the buildings has so far been got ready for the work of the school which forms the sides of the south quadrangle. And even on this portion a great deal of expensive work yet remains to be done. The grouping of the departments round this quadrangle is, roughly stated, as follows :—On the east side are those of surgery and practice of medicine. Anatomy occupies part of this side and a large part of the south side, whilst physiology claims parts of the south and west sides, pathology and midwifery taking up the remainder of the west side of the quadrangle. On the north side is what promises to be an anatomical museum worthy of the rest of the buildings; but so far only the bare walls and the iron supports of a gallery running round the hall are in their places. Meanwhile, it may be noted that into this museum are let several openings, by which ready access will be got to it from each of the departments, to suit whose convenience for teaching purposes the museum specimens will be arranged in corresponding sections. The departure from the Continental system, which had been necessarily followed in the old buildings, of splitting up the practical departments, has in the new buildings been adhered to with the best effect. In the magnificent central dissecting-room, measuring 108 feet long by 30 feet wide, and 27 feet high, not only is practical teaching carried on with perfect thoroughness and efficiency, but it is carried on with an amount of general comfort, and for the benefit of an increased number of students, that could not possibly have been provided for in the old rooms. In this, and in what may be styled the overflow dissecting-room above the first-mentioned, which measures 30 feet long by 20 feet wide, practical teaching can be given to over 500 students, as against 300 in the old rooms. The conveniently placed cloak-rooms, lavatories, demonstration and demonstrators' rooms, are also an immense advance upon what anatomical students had not long ago to put up with. Then, the roomy, comfortable, and well-appointed bone and microscope rooms, are, both of them, in the best sense, aids, and even inducements to study; whilst the opportunity which the latter affords for the investigation of objects of microscopic anatomy would have been gladly welcomed by the predecessors of the present generation of students. Lastly, the lecture-room has been arranged to give comfortable sitting-space for about 500 persons; and the arrangements for profitable tuition and study made by Professor Turner are in keeping with the completeness of the building arrangements.

"In the immediate neighbourhood is the department of the Practice of Medicine. Professor Grainger Stewart has obtained for this department a large and comfortable classroom, with a museum, retiring-room, and five other rooms, which he proposes to arrange for the purposes of practical work in connexion with his course. The class-room, which is provided with a gallery, which last session's experience proved to be happily constructed, so far as hearing and seeing the lecturer are concerned, has its students' door opening on a staircase that enters from the south front of the north quadrangle, and is common to the departments of Anatomy, Surgery, and Practice of Medicine. The class museum is to the west of the lecture-hall, and was last year used as the professor's retiring room. Two compact rooms, which enter from the north side of the lecture-room, will now be used as retiring-rooms for the professor; and to

these private access is had by a spiral staircase opening on to the east front of the north quadrangle. This staircase, and the professor's retiring-rooms, open in turn upon the suite of five rooms which the professor purposes to arrange for practical illustration and teaching in connexion with his chair. One he has already set apart for practical teaching of the use of the ophthalmoscope; and another for that of the laryngoscope. The others he will utilise for purposes which may suggest themselves in the course. In the ophthalmoscope-room, it is proposed, by means of a light placed centrally in the apartment, to enable about six students at a time to practise with this important instrument upon dummy specimens, so as to enable them to gain facility in its manipulation before using it on the living subject. A like plan will be followed in the laryngoscope-room. The Surgery Department, to which Mr. Cheyne, the new professor, will be inducted at the opening of the School next month, was in full working order last session, and its rooms are situated on the same floor with those just described. The lecture-room is laid out much after the same plan as that of the Anatomy Department, being a large theatre, with seats arranged semicircularly round the professor's lecture platform. It does not, however, accommodate so large a number of students as does the Anatomy lecture-room. Attached to it are professors' retiring-rooms, and rooms also in which the practical work of the chair has been, in the past winter, comfortably and successfully carried on.

"As already stated, the Midwifery Department of Professor Simpson is situated at the west side of the south quadrangle. It is entered by a corridor, opening upon the south-west corner of the north quadrangle, and also upon the Middle Meadow Walk; and has, in the first place, a lecture-room, with a compact and ungalleried auditorium, seated for about 250 students. The lecture-room is in communication with the professor's rooms and with the museum. The former consist of a retiring-room and a work-room, whilst the latter is elegantly and conveniently fitted with glass cases and presses and open stands. There is further a large practical room, intended for tutorial classes and original investigation, and supplied with models and other appliances for the thorough training of the students in their practical work.

"But it is perhaps in the departments of Physiology and Pathology that the most striking and manifest improvements are to be found. To take first the department of Pathology, which also is in the western part of the buildings, there is in this a suite of rooms admirably fitted up for the carrying on of pathological teaching, both systematic and practical, and, in addition, several rooms which may be used for pathological investigation of various kinds. It is unfortunate in being entered by an imperfectly lighted stair and corridor, the latter being nine feet wide. Then the dimensions of the lecture-room of the department, like those of all the other departments, have been found to be insufficient to meet the wonderful growth of the school in the past few years. But here complaint ends. Endeavour has been made, by the addition of a gallery, to provide the requisite accommodation in the lecture-room, which is on the upper floor, and opens, with the practical and other rooms of the suite, from a common corridor. The gallery extends round three sides of the room, at the height of about thirteen feet above the level of the lecture platform, is seated for 132 students, and is entered by a spiral staircase situated at each end. Altogether, the room is seated for about 350, allowing 24 inches for each student, and the room is lofty and well-lighted, and will compare favourably with the other class-rooms. Opening into it is the retiring-room of Professor Greenfield, which measures 18½ feet by 15½ feet, with a height of 18 feet, is well lighted and comfortable, and is fitted with ample accommodation for storing diagrams, &c. Opening from this again, and having like it a door to the corridor, is a room of similar dimensions, fitted up as a private workroom for the Professor of the department. A few steps across the corridor at this point bring one to the entrance to the pathological section of the great museum. Farther south along the corridor, and to the right hand, is the large class-room set apart for practical work, perhaps the most beautiful room in the whole building. It measures 39 feet by 40 feet, and has a height from floor to ceiling of 27 feet. It is lighted on its north, south, and west fronts by large windows measuring 16 feet in height and 6 feet in breadth, and is, besides, magnificently fitted with every requisite for carrying on the work of a large practical class. Slate tanks for storing material, troughs, &c., and wash-basins, are placed at intervals round

the room, and there are five long tables in the centre, and also tables fixed by each window, at which students may carry on microscopic work. During the summer session, five classes, each consisting of about thirty-six students, met daily for practical work. Adjoining this is another fine room, measuring 30 feet by 30 feet, and 20 feet high, also most completely fitted up for pathological research, with various apparatus, chemical, &c., and intended for the use of more advanced students. On the floor below are three smaller rooms, intended for special work. These average a little over 40 feet in length by 14 feet in breadth, and each is lighted by three windows placed in the west wall. The north room is set apart and fitted for photographic work, &c., in this department, and possesses a dark chamber and other necessary apparatus for this work. The central room is for chemical and experimental pathological work, and the most southerly room of the three is at present used for storage and work in connexion with preparations for the practical class. In all the rooms which are intended for practical work, the gas and water fittings are most complete; and a large ice-house and cellars for storage, entered from the lower court, complete the accommodation for the Pathological Department.

"In the Physiological Department, presided over by Professor Rutherford, the provision made for carrying on the teaching, practical and systematic, and for experimental work is equally generous and quite as complete. To adapt the lecture-hall, which is in the south-west corner of the building, for the numbers attending the class, certain internal walls had to be removed and the superstructure supported on two large iron girders. With this structural change, a lecture-room which will seat nearly 500 students, and will meet the requirements of the department, without the addition of a gallery—in the mean time at any rate—has been secured. For the practical work of the department, Professor Rutherford has a suite of some sixteen rooms. These are divided between the ground and first floors of the south and west sides of the southern quadrangle. The class museum is placed opposite the lecture-room on the ground floor, and is fitted with the same completeness as has already been noted in the other departments, having a wealth of glass cases, tables, and other requirements. To the back of, and *en suite* with, the class museum are several smaller rooms, designed and fitted for the preservation of subjects for the class demonstrations. Ascending to the first floor, access is got to the practical and experimental rooms of the department. Beneath the large practical pathology class-room are three smaller rooms, in which the teaching of microscopy or histology is to be carried on. Of these, the largest has an area of 33 feet by 21 feet, and it is furnished with ebonised mahogany tables, sinks, water-taps, &c., after the style adopted in the pathology department. A smaller room, intended and arranged for the like work, is in communication with the larger apartment, whilst the students' lockers are placed in a third. Alterations which had to be made on the original plans to meet the needs of the department have lowered the roofs of these rooms considerably in comparison with the pathology room above. The professor's retiring and work rooms are placed in the west side of the building, over the Midwifery class museum, and are admirably furnished for private work. At the end of the lobby from which these enter are the students' lavatories. Opening off a lobby, which runs at right angles to the one just mentioned, is a series of rooms fitted up for the experimental and practical study of physiology, as well as for physiological chemistry, and for the use of the professor's assistant and other purposes of the department."

When these buildings are completed, the University of Edinburgh will enjoy every facility for original investigation which spacious accommodation and the most modern appliances can afford, and it is to be earnestly hoped that each department will produce an amount of original work commensurate with these facilities.

## GLASGOW.

(From our own Correspondent.)

Two cases of poisoning from whisky drinking have been noted in our daily papers during the past week. One man had been drinking in a public-house till a late hour, and on going home he procured a further supply of liquor; shortly

afterwards he fell asleep, and in a few hours fell from his chair, dead. The other case was that of a man who, in drunken bravado, agreed to drink a whole bottle of whisky "without taking it from his head," and did so, with the result that he soon became comatose, and had to be removed to the infirmary.

Another poisoning case, in which a man, his wife, and three children suffered severely from the effects of some irritant poison, is reported, the symptoms being caused by eating from a tin of preserved salmon.

At the last quarterly meeting of the trustees of Anderson's College the proposal to move the medical school, and perhaps also the whole institution, to a more westerly site, was again discussed; but no decision was come to, the matter being left in the hands of the managers for consideration. The medical faculty of the College should know their own business best, but I believe they err in leaving such a noble field as the Royal Infirmary (the largest in Scotland) solely to the little Infirmary School, while their own students, on going westward, will naturally still further block up the already overcrowded wards of the Western Infirmary; nevertheless, they are quite agreed that such a change is eminently necessary for the further prosperity of the school. There are no funds at present in the hands of the College available in aid of this transference, but it is hoped that either the trustees will assist the medical faculty in their projected move, or that the whole College will migrate. One of the directors made some statements, which passed unchallenged, and which form a strange commentary on the swelling statistics published in the College's Calendar and referred to here a few weeks ago. He advanced it as an argument in favour of the proposal to move westward, that as the greater part of the city's population is now to the west of the site of the College, and as the eastern parts of the city are well supplied with other institutions in which popular science and art are taught, the number of students in the evening classes is now considerably less than it was a few years ago. Looking back only ten years, at the old endowed classes, anatomy, chemistry, and natural philosophy, the number of students now is not one-half what it was then!

The grand annual battle of the schools took place at the October meeting of the Faculty of Physicians and Surgeons on Monday last, with the result that the supporters of what is known as the *status quo ante* were triumphant along the whole line. Strangers to Glasgow medical politics should be aware that at the annual meeting of the Faculty, when vacancies occur by rotation in the examiners' board, the representatives of the various local medical schools contest fiercely for the posts, and canvas freely among the Fellows for support, a part of the business much deplored by the President. The object of these contests is, of course, to strengthen the schools, students being probably attracted to that which has most representatives on the Faculty's board of examiners. It is doubtless a bad thing that the Faculty should be made the field for such strivings, but it is not easy to see how it can be avoided. Bad as this is it is scarcely a less evil than the opposite extreme, which is apparently favoured by a large party in the Faculty—namely, a tendency to regard the annual retirement as merely nominal, and to look with extreme suspicion on any proposal to change the *personnel* of the board. The provision that a certain number of examiners should retire every year was surely meant to give an opportunity for the introduction of fresh men into the board at regular intervals.

A fully equipped little hospital, "intended for the care and treatment of the poor when suffering from disease or accident," has been presented to the people of Largs by Mr. John Clark, of Curling Hall, Largs. The hospital proper is a neat, one-storeyed edifice, built of red stone, and standing in its own grounds; the wards, two in number, are lofty, roomy, well lighted, and cheerful, the flooring being of red pine laid in three inch breadths. The building has been so arranged that it can easily be divided into two separate portions, one for accident cases and one for infectious diseases. The officials live in an upper flat, while the offices (laundry, mortuary, &c.) are in a separate building.

Pullokshawa, a suburb of Glasgow, is to-day in the throes of a municipal election, the only noteworthy point about which is that both candidates for the provostship are medical men, Dr. A. Ritchie and Dr. W. Walker.

Glasgow, Oct. 2nd.

## SCOTTISH NOTES.

(From our own Correspondent.)

A PROPOSAL for the erection of a new asylum for pauper lunatics at Aberdeen is now under consideration by the St. Nicholas Parochial Board. It appears that Elmhill House has been several times enlarged, that its accommodation is now overtaxed, and that the Lunacy Board do not consider further extension desirable. In the meantime many of the Aberdeen lunatics must be sent to Montrose, Banff, or Elgin, and additional cost is incurred. It is now decided to adopt the report by a committee of the board, recommending that a parochial asylum should be built, that accommodation should be provided for from 250 to 300 patients, and that the cost should be from £12,000 to £15,000. Though it is thus decided to provide an asylum for the poor of St. Nicholas only, it is the opinion of many members of the board that a house sufficient for the wants of the district should be built.

Dr. Ogston has now formally received all the support, in his candidature for the surgery chair at Aberdeen, predicted in the columns of THE LANCET a few weeks ago. A considerable majority of the professors testify in his favour, and it is noticeable that the whole of the teachers, who are originally Aberdeen men, favour his claims; the staff of the Royal Infirmary are unanimously in his favour; a large number of professors and teachers of surgery at home and abroad express their appreciation of his high scientific attainments; while the profession in the north of Scotland and the present students of the Aberdeen school also present memorials. Mr. F. F. M. Moir's letter of application is published, from which the Home Secretary will see that his experience in teaching is considerable, dating back to a period when he was but thirteen years of age. There is not such an array of favourable testimony on behalf of Mr. Moir as that mentioned in favour of Dr. Ogston; indeed, so far, a singular reticence has been shown in publishing any evidence whatever of his fitness for the responsible position he seeks to fill.

What appears to be a rather serious outbreak of scarlet fever has occurred at Dundee. As typhus, measles, and typhoid were recently epidemic, and still exist in the town, the fact that the authorities have at length been roused to action need not be surprising. They have obtained by their recent local Act compulsory powers of notification, and already it is found that this is of little service while they have such a meagre amount of hospital accommodation for infectious diseases. A small-pox hospital was provided some years ago, and this they propose to utilize; while it is further asserted that the proportion of beds available at the Royal Infirmary, in the event of an epidemic, is too small. A meeting has been held at which the public authorities and the infirmary managers discussed the question, and it is not unlikely that a temporary arrangement may be effected, increased ward space being devoted to fever cases.

A case of considerable interest has just been settled by the Sheriff of Midlothian. It appears that the sanitary condition of certain property in the village of Loanhead was so unsatisfactory that the local authority ordered the proprietor, an Edinburgh lawyer, to have the nuisance removed, and that the defendant denied the title of the pursuers to sue. His lordship, expressing the opinion that by Section 7 of the Public Health Act local authorities have power to sue in such cases, and to appoint committees of their own body to take proceedings, pointed out in detail that the premises were in a filthy condition, and that the state of matters was injurious to public health and offensive to public decency. The defendant must take steps to remove the nuisance.

## PARIS.

(From our Special Correspondent.)

A CURSORY mention was made in THE LANCET of Sept. 23rd of Dr. Felizet's case of gastrotomy. The patient is now convalescent, and I will now complete the account of this case by a description of the operation and the subsequent treatment. Peter Genisca, for such is the name of this spoon-swallower, is a young Swiss of nineteen years of age. On the night of Sunday, Sept. 10th, he was amusing the

customers of the *café*, where he was employed, by introducing a long spoon, such as is used for stirring coffee when served in glasses, into the œsophagus, pushing it as far down as he could and then withdrawing it. The performance was brought to an abrupt ending by the spoon slipping out of his fingers and disappearing down the alimentary canal. The following morning he was seen at the hospital by M. Felizet. Palpation revealed the existence of a foreign body, which projected in the left hypochondrium. Pressure upon this spot was painful, and caused a pricking sensation below the liver. The patient complained also of a feeling of constriction in the epigastrium, of difficulty of breathing, and of a painful sensation with each movement of the diaphragm. There was a constant flow of saliva and mucus from the mouth. Opium and ice were given to allay the pain, but in spite of this no sleep could be obtained, and bilious vomiting set in. This symptom, together with the patient's anxiety and suffering, decided M. Felizet to operate. In order to lessen the chance of the escape of any liquids from the stomach into the peritoneum, and to manipulate the abdominal organs as little as possible, the following plan was devised: A small india-rubber tube was introduced through one nostril into the stomach. The outside extremity terminated in a Y-shaped branch, upon one division of which was a funnel, whilst the other was in communication by means of a tube with a recipient containing ether. To begin with, the stomach was washed out by pouring a solution of bicarbonate of soda into the funnel, and then depressing the end of the tube below the level of that organ, so as to act as a syphon. The patient was then brought under chloroform and the operation continued with antiseptic precautions. An incision was made seven centimetres long, parallel to and one and a half centimetres below the edge of the false ribs, extending from the line of hepatic dullness, three centimetres below and external to the xiphoid appendix, to a point on the left side on a level with the junction of the ninth and tenth costal cartilages. The sheath of the rectus, and some of its fibres were divided, and the peritoneum exposed. Hemorrhage having been entirely arrested by torsion and ligature, the recipient containing ether was plunged into a vessel of water at 60° Centigrade, and the stomach at once became distended by the vapour, and the peritoneum, being divided upon a director, protruded through the wound. Ten sutures in all were then made to fix the stomach to the abdominal wall, the ether being allowed to escape, in order to ascertain whether the juxtaposition of the surface was complete. One spot appearing defective the stomach was distended again, and another suture inserted. An incision six centimetres in length was then made in the axis of the wound. After the vapour had escaped the stomach was found to be perfectly clean and empty. The spoon was felt, lying transversely across the stomach with one end in the pylorus and the other in the greater curvature; it was then extracted without difficulty. After the operation the patient was kept under the influence of morphia by small hypodermic injections. Tea and rum were given as a drink, with small pieces of ice. Antiseptic dressings were applied. The after effects of the operation were not serious. There was no fever or tenderness of the abdomen. The most distressing symptom was great thirst, but this was relieved most satisfactorily by enemata of cold water. Notwithstanding the dressings, the liquids swallowed passed through the wound. On the fourteenth day, a little milk was given, but this oozed through the dressings, and was not renewed. On the fifteenth some meat was tried, but caused uneasiness. On the first of October, a considerable portion of the wound had healed, and all that remains is a fistulous opening, closed by a pad. The patient eats meat, vegetables, and pastry.

## NEW YORK.

(From our Correspondent.)

I ATTENDED the recent meeting of the American Association for the Advancement of Science, at Montreal, Canada, and offer a few notes of papers read there. Professor Alexander Graham Bell explained in detail his methods employed in constructing an instrument for locating the presence of metallic substances in the human body. It will be remembered that such an instrument was twice used upon

the person of President Garfield without success. On the first attempt the failure was due to the imperfections of a hastily constructed instrument, and on the second occasion an area of sound was discovered, which led to the idea that the bullet was within that area. This proved to be incorrect, as the indications were caused by a steel mattress under the President's bed. The instrument now constructed by Professor Bell was recently tested upon the person of Colonel Clayton, who has carried a bullet for many years. The result is stated to have been perfectly satisfactory, and Professor Bell now claims that with his apparatus the presence of a bullet in any part of the human body can be located with accuracy. The principle of the instrument appears to be the use of the telephone in conjunction with the inductive balance invented by Professor Hughes; the action of one set of coils is neutralised by the reversed action of another set. The approach of a metallic body within a certain distance disturbs this state of equilibrium, hence a signal is given. At first no indication was afforded by the instrument beyond two inches; to make it practical this distance had to be extended. Professor Bell now obtains satisfactory results at five inches, and has modified and improved the instrument in other respects, until a degree of perfection has been reached which warrants him in placing the apparatus before the medical profession as a perfect instrument.

Professor A. G. Bell also exhibited the model of an apparatus for producing Artificial Respiration. His idea is to place the subject in a metal cylinder closed with ends of rubber, which should fit tightly around the shoulders and legs. By means of a force-pump, the air can be exhausted from the closed space, when the pressure of the atmosphere forces air through the mouth and nose into the thorax, causing a depression of the diaphragm, and consequent expansion of the abdomen, the alternate rarefaction and condensation of the air confined around the abdomen causing alternate inspiration and expiration.

Dr. William Osler, of Montreal, in speaking of the Microcytes of the Blood, referred to the unsatisfactory explanation of their origin. He said that he had seen their production in the spleen-tissue and in the bone-marrow by a sort of budding from the ordinary red corpuscle. In the conditions under which microcytes are usually found, particularly after hæmorrhages and in profound anemia, he said the red corpuscles often presented great irregularities of outline. The author added that in fresh specimens of spleen and bone-marrow, he had seen these little particles become detached from the blood cells, moving about in the current on the slide, and when so detached presenting all the characteristics and appearances of the microcytes. Dr. Osler has promised me abstracts of other interesting papers which he read on this occasion, and I will probably refer to them later.

Dr. Louis Elsberg, of New York City, read a paper on Plant Cells and Living Matter. I will postpone a description of Dr. Elsberg's views, as explained in his paper, and refer to an interesting discussion which it provoked. All living matter—bioplasm—is supposed to be made up of reticulations of living substance, with inert matter filling the reticulum. It is said that the reticulum can be easily demonstrated by microscopic observation; that one has only to look for it, and it can be found; that it exists in the white blood-corpuscles and in the amoeba, and can be seen in them without reagents. At the conclusion of the paper, Dr. Carl Seiler and Mr. Romya Hitchcock, while reserving their opinion on the theory in question, asked information of Dr. Elsberg "just how the network could be found." They acknowledged that they had looked for it, but could never find it. In reply, Dr. Elsberg stated that no preparation or manipulation was necessary; the object has merely to be placed under the microscope with a suitable objective, and the network could be seen at once; beyond this Dr. Elsberg would give no information. The members of the Biological Section (Dr. Elsberg excepted) had never seen the reticulations, and doubted their existence. They are shown illustrated in various standard works. May I ask have they been seen by any English microscopist? If so, will he state the conditions under which their presence can be demonstrated?

Professor W. A. Rogers, of Harvard College, who is favourably known for the very exact ruling of micrometric scales, called attention to the fact of a claim set up by Mr. Fasolat, of Albany, N.Y., that he had succeeded in ruling lines 1,000,000 to the inch. Professor Rogers doubts if lines as close as 152,000 to the inch have yet been resolved by a

microscope. It is therefore impossible to test the claim of those who profess to rule lines above that limit. As an interesting test of human vision, Professor Rogers stated that single lines 155,000 of an inch in width can be seen without a microscope.

Dr. Thomas Taylor, of Washington, showed his new Freezing Microtome, which was much admired by those present. The centre of the microtome is fed by a rubber tube with iced water and salt supplied from a pail placed on a bracket; there is also a discharge tube leading to a lower pail, by which means a circulation is kept up. No necessity arises for hardening or otherwise preparing tissue if this instrument be used; the substance is immersed in gum water, and frozen in a condition for cutting in less than one minute. To regulate the thickness of the section, the outside rim of the microtome plate has an engraved scale and revolvers, and a pointer indicating the thickness. Several members present, who have used every form of microtome, acknowledged that Dr. Taylor's was the most simple and perfect as yet made. Dr. Thomas Taylor is the microscopist to the Agricultural Department at Washington.

I examined two hospitals at Montreal, and will first speak of the Montreal General Hospital. The building is far from creditable to a city which boasts of the "remarkable number and variety of its philanthropic institutions, and of the number of its churches." Of the latter one has evidence in every street, Mark Twain having at a public dinner expressed his regret that he could not throw a brickbat without breaking a church window. I therefore regretted to find the city hospital in such a poor building, the interior having the appearance of a workhouse. The medical staff appear to be doing their best under the circumstances, and admit the want of accommodation and a suitable building. While the building is a disgrace to the city, the citizens are charged by the hospital authorities with failing to contribute the usual means for its support. The last report shown to me—1880-81—indicated an increase of the number of patients, and of course an increase in the expenses incurred. In the face of which the secretary states, "it is a matter of regret and disappointment" that the voluntary contributions had fallen short even of the last year by the sum of nearly 50,000 dollars. I fear that in the seventy-four large and costly churches of Montreal the parable of the good Samaritan is preached with very poor effect. The wards of this hospital were clean and creditable to the management, but the inconvenience of limited accommodation was apparent everywhere, and a proper classification was simply impossible. A little chamber with a few old raised benches is called the operating-room, and does duty also as a chapel. I presume the operating-table, covered with a cloth, is used for the communion, the box of sawdust under such a covering not being visible. The hospital was full to its limited capacity, and three cases of typhoid fever had just terminated fatally.

The Hôtel Dieu, a Catholic Institution founded in 1644, next claimed my attention. This is a combination of a nunnery and a hospital, each occupying a wing separated by a spacious church. The present building was completed in 1861, and is a handsome stone erection situated in a garden enclosed by high walls. The entrance doors of the hospital are kept closed, and on ringing a bell you find yourself in the presence of a nun. A request to inspect the hospital was courteously acceded to, and I forthwith examined every room under the guidance of a sister of mercy, who explained in detail their system of management. The contrast to the hospital I had just left was indeed great; instead of having to cut and contrive with limited means, here they appeared to possess *embarras de richesses*. I regretted, however, to find so many beds unoccupied at a time when the general hospital was crowded beyond its limit. Religious instruction and cleanliness appeared to be the chief ends in view. Nuns were reading aloud in every ward, and the wood floors had been scrubbed until their texture was destroyed, presenting a soft velvety sensation to the feet. The hospital has a high reputation for good surgical work, and the arrangements for the care of the sick are doubtless of a very high order, the eighty professed sisters and novices devoting their lives to that object with a tender regard for the patients under their charge. I was surprised to find the wards filled with heavy four post bedsteads with white dimity drapery on top and enclosed with four curtains. It seemed a defiance of all modern rules for hospital management. Although over 3000 persons annually receive treatment at this hospital, no house-surgeon was in attendance at the time I called, and in

the absence of all members of the medical staff I found it difficult to obtain information respecting many important details of management. In the grounds of the hospital was a building, then closed, which I understood to be a medical school. A very creditable monthly journal is published in French relating to the cases treated at this hospital.

## Obituary.

J. T. CLOVER, F.R.C.S. ENG.

JOSEPH THOMAS CLOVER was born at Aylsham, Norfolk, in 1825. He received a general education at Grey Friars Priory, Norwich, and at its conclusion he became a pupil of the late Mr. Gibson, a surgeon of high standing and large practice in that city. In 1842 he was entered as a dresser at the Norfolk and Norwich Hospital for two years, and it would appear that the malady which more or less marred his working in after life began at this time, for there is an entry in the hospital book which shows that he was absent from ill-health nearly four months. In 1844 he commenced his studies at University College, London, and the same defective health is proved by a letter received by the writer of this notice (then a senior student) from the late Dr. Lubbock, of Norwich, telling of his fear that his young friend, for whom he felt so warm an interest, would injure his frail health by overwork. It was probably on this account that Clover did not compete for honours in the various classes, but he was regarded by his fellows and teachers as one of the most promising and prominent students of his time, and we find him, after filling the duties of dresser, clinical clerk, and physician's assistant, elected as house-surgeon to Mr. Morton, and subsequently to Mr. Syme in January, 1848. Such was the confidence in his capabilities and steadiness felt by the Medical Committee that in August of that year he was made the responsible head of the working staff of the hospital and became resident medical officer. So highly did Mr. Syme estimate his house-surgeon's services, that on his return to Edinburgh he offered Clover a similar position at the Royal Infirmary. This, however, he was unable to accept, because of the more important appointment at his old hospital which was offered to him. During the five years he held this office, the cholera epidemic of 1849 occurred, which taxed to the utmost the courage and endurance of all hospital residents, and the duties also included the administration of chloroform to all who needed it. In 1853 he settled in practice in Cavendish-place, and there he resided until the sad event of last week. Patients and work came to him quickly, so quickly that had he enjoyed a fair measure of vigour and health, with the sterling qualities he was known to possess, there can be little doubt that he would have reached a high position amongst the leading surgeons of his day. Periods, however, of disabling illness, not unfrequently recurring, obliged him, by degrees, almost to relinquish ordinary practice and to restrict himself, however unwillingly, to the administration of anæsthetics. In this important department of practice it is needless to say he was pre-eminent. Quite early in his career he commenced his inquiries and experiments; it is probable that he was present in the theatre of the University College Hospital during the performance of that first successful operation under ether, in England; and, if the scene impressed him as profoundly and vividly as it did others, it might well incite him to thought and study. The operation was a thigh amputation. Mr. Squire administered ether; the patient inhaled it without a movement; Liston hurriedly removed the limb (in thirty seconds), and the ominous silence of the patient, so unusual in those days, caused anxiety for his life. Presently he awoke, and when the cloth was removed from his stump, and he saw that his leg was gone, the unbounded wonder and delight of the patient was scarcely greater than that of the spectators. The great surgeon was almost overcome with joyful emotion as his mind grasped the full meaning of this new era in surgery, which had just opened with such a startling, unexpected, and complete success. In the development of this discovery, after the first few years, during which Dr. Snow was the leading spirit, and chloro-

form had supplanted ether, Clover took a prominent part. The potency and danger of the new agent soon showed themselves by fatal accidents. He saw that some of these were due to faulty administration, and he set himself to discover a means by which the chloroform vapour could be applied in definite, well-ascertained strength. His mind was markedly of a constructive and contriving order; his knowledge of mechanics and his inventive faculty were great, and, after many trials and much experimenting, he constructed a portable bag, which he ingeniously filled with vapour of safe strength. When the chloroform committee of the Medico-Chirurgical Society conducted their work they chiefly used this bag. Clover, although not a member of the committee, attended most of the meetings, carried out many experiments, administered the anæsthetic, and so aided the work as to secure the fullest acknowledgment and thanks of the members. He was appointed chloroformist to the Westminster, University College, and the Dental Hospitals. He became the companion, in their operation cases, of very many of the chief surgeons and dentists of London. The double anxiety which all surgeons feel so keenly when they are compelled to trust the anæsthetic to inexperienced hands was never felt when Clover was present; he never hesitated to push the agent, when necessary, to the very verge of danger; he would use it when organic visceral disease was known to exist; but his resolute courage was governed by caution and a vast experience. When other agents came to displace chloroform, with open mind and without prejudice he set about to discover their respective uses and merits; he entered into discussion on the various points in the medical journals and at scientific meetings, and, if I mistake not, an article on anæsthetics by him will shortly appear in the Dictionary of Medicine, edited by Dr. Quain, now immediately forthcoming. In other departments of surgery Clover, with his fertile brain and inventive faculty, produced many improvements and new adaptations, but chief amongst them was his exhausting bottle and catheter for the removal of calculous debris from the bladder after lithotomy. If the idea of suction belongs to Sir P. Crampton and others, to Clover is due the credit of perfecting the apparatus by which to accomplish it, while to Bigelow belongs the thought of continuing its use at one or two prolonged sittings until all the stone is removed.

Such is a brief record of Clover's professional work and life; to speak of him as a man and a friend is easy enough, for surely no blemish or fault can be found in his blameless life, which friendship might wish to hide but truth would compel to mention. Every man has some few prominent points of character which give a tone to his whole life. These, in Clover, were his gentle modesty, his absolute unselfishness, and his active sympathy with the joys and sorrows of others. He had no "push," no ostentation or love of display. He worked steadily; his happiness consisted in honestly doing the duty which lay clear before him. None ever heard him speak harshly or unfairly of any; he was without guile or bitterness. He had hosts of friends, for he made many and lost none. Reference has been made to his ill-health. This consisted in chronic pulmonary disease, which, during many years, had frequent periods of arrest and frequent outbursts. In the grey and silent days of this depressing illness he was seldom depressed; as year after year travelled away, leaving his stock of health and strength a diminishing quantity, his cheerfulness endured, and was wonderful; he was contented and happy, resolute to work and help others so long as failing strength permitted; but when the end approached he murmured not, but contentedly resigned himself to the inevitable. "His end," writes Dr. Sydney Ringer, his constant friend and medical adviser, "was quite in keeping with his whole life—gentle, amiable, uncomplaining, grateful, to the last. The world wants one true man since he was taken away."

Mr. Clover has left a widow, daughter of the late Rev. T. C. Hall, Prebendary of St. Paul's, and four children.

ROBERT WISHART LYELL, M.D., F.R.C.S.

THIS young surgeon, who has been suddenly carried off at the outset of a career of great promise, was born in London in 1849, and received his early education at St Olave's Grammar School, Southwark. Already he evinced considerable talent and industry, so that when proceeding to King's College he obtained the distinction of Warneford Scholar. He

passed through the whole of his curriculum at King's College, gaining the esteem of his teachers and fellow-students. In 1871 he graduated in medicine at the University of London, taking honours in all the subjects of the examination; and in 1872 he obtained the degree of M.D., and was also appointed house-physician to the Seamen's Hospital, Greenwich. Soon after this he seems to have decided to turn his attention rather to the pursuit of surgery than that of medicine; for in 1873 he was elected house-surgeon to the Royal Infirmary, Manchester, an office which he held until his return to London at the close of 1874 to take up the appointment of surgical registrar at the Middlesex Hospital. His path was now clear before him, and for the remaining seven years of his life the main part of his labours was within the walls of this hospital. Four years of this period were passed in the post of surgical registrar, which, owing to the cancer department at this hospital, is by no means a sinecure. Dr. Lyell evinced much assiduity and scientific knowledge in this office; and his annual reports of the surgical practice of the hospital are among the best of their kind, and upon their compilation he must have bestowed much labour. A few months after his appointment as registrar, the School Committee made him tutor, feeling that few could discharge its duties more satisfactorily. As a proof of the correctness of their judgment it may be pointed out that he continued to hold the office until his death, and year by year the students have learnt to appreciate highly the value of his instruction and help. Added to this in 1879-80 he undertook the superintendence of the post-mortem examinations of the surgical cases, at the request of the Committee; and the aid thus rendered to the pathologist was invaluable. It might be thought that all this was work enough for any man to have undertaken, but Lyell took up other duties still. He had long a desire to practise ophthalmic surgery, and became clinical assistant at the Royal London Ophthalmic Hospital, Moorfields, besides being elected to the Great Northern Hospital as ophthalmic surgeon, and comparatively recently he was elected assistant surgeon to the former institution. But he followed this special branch only as a part of his general pursuit, and as a vacancy occurred in the surgical staff of the Middlesex Hospital in 1879, he applied for and was elected to the office of assistant-surgeon.

The medical world in general knows hardly anything of Lyell, for he published but little; and in an age when the facilities for publication are so abundant it is remarkable for this to be said of one to whom many opportunities were given of observing disease and adding to knowledge. Doubtless it would have been different had he not been so hemmed in and hampered by the necessary routine of the practical duties he had undertaken. He certainly was never idle, and took far too few holidays to be consistent with the maintenance of health in a not over-robust frame. Indeed, he was always at work, and worked for others as well as for himself. Those who knew him best could not help fearing that he undertook too much; but this they could never get him to admit, and although he was industrious beyond measure, there can be no doubt that he was overtasked. Had he lived, future years might have seen the fruit of his labours in a form more obvious to the world at large; but dying as he has done, more literally in harness than often happens, he has been deprived of any such opportunity of becoming known to the world. Such published work as has appeared from him fully bears out the high opinion that his friends formed of him. In addition to the Surgical Reports of the Middlesex Hospital for 1875-9, he served as Secretary to the Committee of the Clinical Society upon Excision of the Hip, whose report was presented last year; and it may be remembered that in conjunction with Dr. Powell he read before the Royal Medical and Chirurgical Society a case of Drainage of a Pulmonary Cavity. We believe he was also engaged at the time of his death in connexion with the new edition of the System of Surgery, which is being prepared under the joint editorship of Messrs. T. Holmes and Hulke.

Dr. Lyell had been assiduously at work during the past two months in his hospital practice, and was preparing his introductory lecture when the fatal blow came. On Saturday evening, the 23rd, he had a rigor; but he fancied only that

he had taken a severe cold, and could hardly be persuaded by his friend and colleague Mr. Andrew Clark, who saw him on Monday morning, to desist from his work at the lecture. It was plain that his illness was graver than he himself thought, and Dr. Cayley saw him in the course of the day, and attended him throughout. On Tuesday the physical signs of pneumonia were developed, but although there was high fever his strength was well maintained for some days. He was, however, not able to withstand the advance of the disease, and on Sunday, the 1st instant, his condition became very grave, and he died the following morning at nine o'clock.

Of a retiring disposition, good-natured to a fault, so that he was always willing to assist, Dr. Lyell has fallen, we fear, a victim to his love of work; for physically he could hardly be considered a strong man, and yet he submitted to the wear and tear of London hospital practice to an excessive degree. His death came just upon the day when his friends and pupils were assembling at the Middlesex to give him a hearty welcome in his capacity of introductory lecturer. Many learnt for the first time on entering the door of the hospital that the lips whose utterances they had come to listen to were sealed in death; and to all, the necessary proceedings of the opening day were clouded by this one mournful fact. It will be long before the event of that day passes from the memory of those who, knowing what a loss had been sustained to their hospital and to surgical science, felt also the bitterness of a personal bereavement.

#### STAFF-SURGEON W. ST. GEORGE DAVIS, R.N.

THE death is announced of a veteran in the medical department of the Royal Navy, in the person of Staff-Surgeon William St. George Davis, which took place at Hove, near Brighton, on the 30th ult., aged ninety-six. The deceased was the "father" of the medical branch of the navy. He entered the service as far back as 1806. In 1808 he passed his examination for naval surgeon, and was promoted to the rank of surgeon in the same year. He had seen much active service, and was present at many of the numerous sea fights which took place at the early part of the present century. For his services he was awarded the Naval Medal with three clasps. The deceased retired from the department in 1829.

### Medical News.

**APOTHECARIES' HALL.**—The following gentlemen passed the examination in the Science and Practice of Medicine, and received certificates to practise, on Sept. 28th:—

Brinton, Roland Danvers, College-terrace, Balize-park.  
Mac Donogh, Wm. Frederick, Clapham-park-road.  
Plimmer, H. George, Anerley-road, Upper Norwood.  
Rigby, Percy Alfred, Westoby-terrace, Earl's-court.  
Smith, William Herbert, Weston, Bath.

The following gentlemen also on the same day passed the Primary Professional Examination:—

Arthur Ogle and W. P. Bassett-Smith, Middlesex Hospital; Claude S. Sparkes, King's College.

AN inquiry is proceeding respecting the desirability of establishing a local board for Seaford.

ON Saturday last the Duke and Duchess of Westminster opened a Convalescent Home in connexion with the Chester Infirmary.

THE 90th section of the Public Health Act, 1875—that, namely, referring to houses let in lodgings—is officially declared to be in force in the district of Isleton and Isleworth.

OWING to the prevalence of infectious diseases in Sunderland, the School Board have cautioned their officers not to enter houses when making inquiries concerning absentees from school.

AT the meeting of the Board of Guardians of the City of London Union on Sept. 27th, in reference to a letter received from the Local Government Board suggesting the need of certain alterations in the Homerton workhouse, it was decided to refer the whole matter to a special committee, which should report upon it fully.

THE committee of the Essex and Chelmsford Dispensary and Infirmary have resolved to proceed with the erection of the new building, the tender placing the cost at £3485 having been accepted.

**GUY'S HOSPITAL MEDICAL SCHOOL.**—The entrance scholarship of 125 guineas in arts has been awarded to Mr. John Lloyd Roberts of Llanrwst, and the entrance scholarship of 125 guineas in science to Mr. William Frederick Clarke of Kensington.

THE Holborn guardians are advised by the Local Government Board to provide an entirely new workhouse for the union, planned to accommodate, in the first instance, not less than 600 inmates, and capable of further enlargement, as may be found necessary.

THE sum of £2600 has been given to the University College Hospital, London, by Mrs. Nathaniel Montefiore. It is to be invested for the permanent endowment of a bed in memory of her late brother, Sir Francis Henry Goldsmid, and a cot in memory of her son, Mr. Leonard Montefiore.

THE novel dramatic entertainment conducted recently by Dr. George Macdonald and his family in the Pavilion, Brighton, on behalf of the local Association for Nursing the Sick Poor, has, it appears, been very successful, and will result in a considerable addition to the funds of the charity.

**CASUAL WARDS ON SUNDAY.**—At the meeting of the Hackney Guardians on the 27th ult., Dr. Millar informed the Board that he went through the casual wards on Sunday, and what he saw was rather unsatisfactory. He moved that a committee be appointed to have the oversight of these wards, which seemed to have no regular supervision. The motion was carried.

**PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.**—On Wednesday the session of this Society was opened at Bloomsbury-square. Mr. Cartishe presided, and the prizes awarded to the successful students were presented by Mr. James Ince, who also delivered the inaugural address. Professors Redwood and Bentley gave favourable reports of the classes of chemistry and pharmacy and of botany and materia medica respectively; whilst Professor Atfield's account of the work done in the laboratory last session was also satisfactory.

**LONDON FEVER HOSPITAL, LIVERPOOL-ROAD.**—The resources of this valuable institution have recently been taxed to the utmost by a serious outbreak of scarlet fever in the district. Every available bed in the hospital is now in use; and unless additional accommodation is promptly provided the house directors, much against their wish, will have to begin refusing admittance to new patients. This, in the circumstances, would be a serious public calamity; but, unless the necessary funds are at once supplied, the managers are helpless, and will be compelled to reduce the outlay at a time when the pressing necessity exists rather for increasing the accommodation.

**SCARLET FEVER IN LONDON.**—At the meeting of the Metropolitan Asylums Board on Saturday last, Mr. E. Galsworthy presiding, Sir Edmund Hay Currie drew attention to the fact that there were at the present time 500 cases of scarlet fever in the Homerton, Stockwell, and Deptford Asylums—cases brought from all parts of London; and he moved that the Local Government Board be requested to give its permission to the opening of the Fulham and Hampstead Hospitals for the reception of cases, more especially of those which might arise in the parishes and unions near those asylums. In the course of the proceedings protests were made by the members representing the southern and eastern districts against the asylums in those districts being used for all the fever cases in the metropolis, and it was stated that the poor fever patients of Fulham and Hampstead were sent to the south and east while there were empty hospitals in their own districts. The chairman suggested that the Board should proceed in regard to one hospital at a time, and it was agreed to ask the Local Government Board to permit the opening of the Fulham Asylum for fever cases.

## BOOKS ETC. RECEIVED.

- ALLEN, W. H., & Co., London.  
On Duty under a Tropical Sun. By Major S. Leigh Hunt, Madras Army, and Alex. S. Kenny, M.R.C.S.E., A.K.C. pp. 138.

## Medical Appointments.

*Intimations for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning at the latest.*

APPLEYARD, JOHN, F.R.C.S. & M.B. Lond., has been appointed Honorary Surgeon to the Bradford Infirmary, vice Philip Miall, retired.

BARRINGTON, FRED. ALBERT, L.R.C.S.I., has been appointed Medical Officer for the Western District of the Freebridge Lynn Union.

BLAGO, ARTHUR F., M.R.C.S., L.S.A. Lond., has been appointed Resident Medical Officer to the Rochdale Infirmary, vice Stevenson, resigned.

CARTER, THOMAS, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer and Public Vaccinator for Richmond (Yorkshire) and the Union, vice Atkinson, resigned.

COLLYNS, R. J., M.R.C.S., L.R.C.P., has been appointed House-Physician to the Royal Hospital for Diseases of the Chest, City-road, vice Duncan Burgess, M.A., M.B., whose appointment has expired.

CUMBE, JOHN BATTEN, L.R.C.P. Ed., M.R.C.S., L.S.A. Lond., has been appointed Medical Officer for the Wargrave District of the Wokingham Union.

DOUTY, J. HARRINGTON, M.R.C.S., L.S.A. Lond., has been appointed Second Assistant Medical Officer to the County and City of Worcester Pauper Lunatic Asylum.

FIELDEN, JAMES, M.R.C.S., has been appointed Medical Officer for the St. Faith's District and Workhouse, St. Faith's Union, vice Hawkes, resigned.

HITCHCOCK, CHARLES KNIGHT, M.D., M.A. Cantab., has been appointed Deputy Superintendent to the Warnford Asylum, Oxford, for six months from the 2nd inst.

LAEN, T. LENNARD, B.A., M.B., C.M., of Bute Docks, Cardiff, has been appointed Medical Inspector of Seamen to the Board of Trade for the Port of Cardiff, vice Dr. T. O. Pratt, resigned.

NEWCOMBE, FRANK, M.R.C.S., L.S.A. Lond., has been appointed Medical Officer for the Dunham District of the East Retford Union.

O'REILLY, ARCHIBALD THOMAS, M.R.C.S., has been appointed Government Medical Officer, also Medical Officer to the Stanthorpe Hospital, Queensland.

POWELL, SCUDAMORE KYDLEY, M.D. Dur., M.R.C.S., L.S.A. Lond., has been appointed Medical Officer for the Madley District of the Dore Union.

RINGER, SYDNEY, M.D., F.R.C.P. Lond., has been appointed Consulting Physician to the North-West London Hospital, Kentish-town-road, in conjunction with Dr. Andrew Clark.

ROBERTSON, DONALD W., L.R.C.P. Ed., M.R.C.S., has been appointed Medical Officer for the Pickering District and the Workhouse of the Pickering Union, vice Smalles, resigned.

ROSS, DOUGLAS M., M.B. Ed., M.R.C.S., has been appointed Medical Officer to the Brighton Workhouse and Warren Farm Industrial Schools, vice D. Richards, M.R.C.S., L.S.A. Lond., resigned.

SANGSTER, CHARLES, M.R.C.S., has been appointed Surgeon to the D Division of the Metropolitan Fire Brigade, vice G. F. Browne, resigned.

SMITH, WILLIAM BEATTIE, L.R.C.P. Ed., F.R.C.S. Ed., has been appointed Deputy Medical Superintendent of the Ararat Lunatic Asylum, Victoria.

UNWIN, JOHN BROOKE, L.R.C.P. Ed., L.R.C.S. Ed., has been appointed Medical Officer for the Dunchurch District of the Rugby Union.

WATSON, FRANK S., M.R.C.S., L.S.A. Lond., has been appointed Colonial Surgeon to St. Helena.

WEBSTER, GEORGE LEONARD, M.R.C.S., L.S.A. Lond., has been appointed Medical Officer for the Bewdley District of the Kidderminster Union.

WICKHAM, HENRY, M.R.C.S., L.S.A. Lond., has been appointed Medical Officer for the Fourth District of the Ormskirk Union.

WILSON, J. MITCHELL, M.B. S.Sc. Cert. Camb., has been reappointed Medical Officer of Health for the Rural Sanitary Districts of the Doncaster, Goole, Selby, and Tadcaster Unions, and the Goole, Selby, and Tickhill Urban Sanitary Authorities, for a term of seven years.

## Births, Marriages, and Deaths.

### BIRTHS.

HAY.—On the 10th ult., at Aden, the wife of Surgeon-Major G. W. R. Hay, I.M.D., of a daughter.

HUNT.—On the 8th inst., at 101, Queen's-road, Dalston, the wife of Joseph W. Hunt, M.D., B.S. Lond., of a daughter.

JAMES.—On the 29th ult., at Napton Villa, Biggleswade, Beds, the wife of Alfred James, M.R.C.S., L.S.A. Lond., of a daughter.

MITCHELL.—On the 25th ult., at Old Rain, the wife of Patrick Mitchell, M.D., of a son.

STOCKER.—On the 28th ult., at Peckham House, Peckham, the wife of Alonzo H. Stocker, M.D., of twins (sons).

TURNER.—On the 26th ult., at Harcourt, Bournemouth, the wife of John A. Turner, M.B., C.M., of a daughter.

### MARRIAGES.

CAMERON—THOMPSON.—On the 27th ult., at Skene, John Cameron, L.R.C.S.E., of Kintore, to Elizabeth Marion, eldest daughter of the late James Thompson, Merchant, of Buckie.

FOULDS—NICHOLLS.—On the 26th ult., at Christ Church, Lea, Kent, Henry John Foulds, M.R.C.S., of Derby, to Marianne, fifth daughter of the late John Nicholls, of Champion-hill, Surrey.

HUTTON—GILFORD.—On the 3rd inst., at Holy Trinity, Micklegate, York, E. R. Hutton, L.R.C.P.L., of Tottenham, Middlesex, to Rose Gilford, eldest daughter of W. Gilford, late of North Luffenham, Rutland.

LAEN—SINCLAIR.—On the 6th ult., at Wick, N.B., by special proclamation before the High Sheriff of Caithness, Thomas Lennard Laen, B.A., M.B., C.M., of Cardiff, to Helen Emily, youngest daughter of Sinclair of Achinabest, Reay, Caithness.

MARTIN—BAYNES.—On the 21st ult., at St. Oswald's, Knutsen, John M. H. Martin, M.D., of Arnheim, Blackburn, to Thomasine Edith, younger daughter of the late John Baynes, J.P., D.L., of Blackburn.

PRICE—GRANTHAM.—On the 4th inst., at the Cathedral, Manchester, by the Rev. R. W. Arthy, Thomas Price, Surgeon, of Manchester, to Fanny, daughter of John Grantham, of Rothay-place, Old Trafford.

WILLIAMSON—BRUCE.—On the 28th ult., at Bridge of Allan, by the Rev. R. P. Watt, of Edinburgh, James M. Williamson, M.D., of Ventnor, Isle of Wight, to Janet Ellis, daughter of the Rev. Wm. Bruce, D.D., of Edinburgh.

WOOD—GOULSTON.—On the 27th ult., at Holy Trinity, Newington, Arthur George Wood, M.R.C.S., L.R.C.P., & L.M., to Ada Jane, younger daughter of Edmund Goulston, of Trinity-square, S.E.

### DEATHS.

CLARKE.—On the 1st inst., at Great Yarmouth, Robert Whitmore Clarke, Deputy Inspector-General R.N. (retired), aged 71.

DAVIES.—On the 20th ult., at Hova Villas, Cliftonville, Brighton, W. St. G. Davies, M.D., Staff-Surgeon, R.N. (retired), aged 96.

HART.—On the 28th ult., suddenly, of heart disease, Robert Alfred Hellingas Hart, L.S.A. Lond., only son of the late Walter Hart, M.R.C.S., of Stonessend House, Southwark, London, aged 28.

LYELL.—On the 2nd inst., at Harley-street, Cavendish-square, Robert Wishart Lyell, M.D. Lond., F.R.C.S.E., aged 83.

MORE.—On the 26th ult., at Chapel-street, Salford, Huseon More, L.R.C.P., aged 38.

SHANN.—On the 2nd inst., at his residence, 69, Petergate, York, George Shann, M.D., aged 73.

UNTHANK.—On the 1st inst., at Derby-road, Nottingham, Anthony Unthank, M.R.C.S., L.S.A. Lond., aged 66.

WEST.—On the 29th ult., at Yeolmbridge, Edward Lawrence West, M.R.C.P. Ed., M.R.C.S., of Launceston, aged 58.

*N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

## Notes, Short Comments, and Answers to Correspondents.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*All communications relating to the editorial business of the journal must be addressed "To the Editor."*

*Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."*

## "MEDICAL OPPOSITION TO IMPROVED REMUNERATION TO MEDICAL MEN."

WE recur to this subject in connexion with Dr. Shorthouse's letter of last week, in which he assumes that Dr. Barnes is the correspondent on the strength of whose statement we "made," as he puts it, "an attack on him." It is always dangerous in an argument to assume anything. The present case is not an exception. Our comments were based on an elaborate letter in the newspapers on the frequency with which instruments should be used in midwifery, sent us by a stranger to both Dr. Barnes and Dr. Shorthouse. But that is a point of no importance when the dispute has actually got into the newspapers. There are two points in which we seem to be at variance with Dr. Shorthouse, and we fear must continue so, much as we regret to differ from him. The first is the seemliness of a medical guardian who, by what may be called a providential illness, was hindered from attending a meeting of the Board at which a reasonable request to raise a medical officer's salary was refused, taking up the cudgels against the medical officer in the newspapers, and suggesting that his bill of extras was raised unduly by a too frequent use of instruments. The vote had gone against Dr. Barnes without the assistance of Dr. Shorthouse. It is never seemly to be the accuser of the brethren. Here it was, to say the least, unnecessary. The second part of our difference from Dr. Shorthouse has reference to our statement that professional opinion is in favour of a more frequent use of instruments, and that there are the gravest reasons for not leaving lingering labours to take their own course. It is somewhat surprising that Dr. Shorthouse should dispute either of these propositions. It is a matter of notoriety that the best practitioners in town and country perceive the danger of prolonged labour especially in the second stage, and that the forceps, or some instrument with a similar purpose, is used more frequently and with the most beneficial results. Let us change the basis of our opinion from common notoriety to something more definite. The late Dr. Thomas Edward Beatty, whose father took the lead in Ireland in the more frequent use of forceps, tells us that when he read in 1842 a paper on the use of the forceps before the Obstetrical Society of Dublin, a gentleman, who had been once Master of the Lying-in Hospital and for forty years had enjoyed one of the largest practices in Dublin, stated that he had *once tried* the forceps and failed. How different the case in Ireland now. But Dr. Shorthouse would like an English opinion, and, in spite of the name, will admit its force. Dr. Robert Barnes ("Obstetric Operations," second edition, page 53) says, "In no respect has modern midwifery given more satisfactory evidence of progress than in the extending practice of applying the forceps to obviate delay in the second stage of labour." We disapprove of meddling midwifery as much as Dr. Shorthouse does; but labour is a painful and perilous process if unduly prolonged, and as it is to the infinite credit of medical men to devise gentle and safe means of shortening it, it is to the credit of medical guardians to be generous in judging fees charged for the use of such means.

## "MEDICAL OPPOSITION TO IMPROVED REMUNERATION TO MEDICAL MEN."

To the Editor of THE LANCET.

SIR,—Dr. Shorthouse makes an assertion that the forceps are required in only 1 case in 600 or 700. This I take to be very far-fetched indeed. The statistics of the Royal Eastern Maternity, which he quotes, are not to be relied upon as being the rule, for they are founded on a condition of data the most favourable and the most unusual. Would we, for instance, compare the death-rate in a well-appointed fever hospital, with all its hygienic surroundings, its skilled nurses, &c., with that of the fever dens of the metropolis? With regard to the said statistics, I may point out that in the year 1820 we find the average of forceps cases 1 in 550, and the average of craniotomy cases 1 in 300. Every practical man is bound to admit that such a comparison of forceps with perforator is utterly at variance with his own experience. The statistics given by Churchill, when the sources of information are taken individually, show a divergence of opinion as to the use of the forceps, from 1 case in 10 to 1 case in 300. In Leishman's valuable work we have twelve conditions given in which the forceps may be required, and, as far as my experience serves me, one or other of those conditions will arise in about 1 case in 30. I can give the exact particulars of 15 cases in 330, in which their use was imperatively demanded to save mother or child, or both; whilst I can add 11 other cases where I used them to terminate a protracted labour, which reason I hold perfectly justifiable, not only in the interests of the mother, but also those of other patients awaiting my services. Dr. Shorthouse must bear in mind that the parish doctor is bound to discharge duties other than obstetric ones, and also that in the poverty-stricken homes where he goes he cannot leave his patient in suffering upstairs whilst he adjourns to the drawing-room or the library. Amongst the poorer classes the doctor is sent for only as a *dernier resort*, in the belief that he can do something more to relieve the sufferer than the friendly neighbour or midwife who nurses the patient has done.—I am, Sir, yours, &c.,

Oct. 2nd, 1882.

HENRY LOVE, M.B. Univ. Dub., &amp;c.

To the Editor of THE LANCET.

SIR,—In Dr. Shorthouse's letter on this subject last week there are two conclusions drawn which appear to me to be entirely fallacious. In the first place, the large amount of "extras" is held to be a reason for considering the salary of Dr. Barnes sufficient. Now, to anyone conversant with the working of unions, it must be well known, seeing the comparative unfrequency of cases that can be charged for as "extras," that a very great amount of work must be done in the ordinary way. The amount of "extras" seems to me to be an argument in favour of the salary being increased. In the second place, Dr. Shorthouse's reasoning in the matter of the statistics of forceps cases is eminently misleading; for, in the majority of unions, an order is only given when a midwife is unable to complete delivery, or, when from some previously ascertained cause, a bad labour is anticipated. A medical neighbour of mine, who holds a large union appointment, told me only the other day that it was the exception in his case to get a parish midwifery case where instrumental interference was not necessary.

Everyone will agree with Dr. Shorthouse as to his right as a guardian in checking over-charges on the part of his medical officer; but I venture to think he is not justified in using statistics in the way he has done without some explanation, for it is evident that such statements must cause that part of the general public who may read them to look upon Dr. Barnes as either a designing man or a bad practitioner.

I am, Sir, yours faithfully,

Shipdham, Oct. 2nd, 1882.

IRVINE K. MILNE.

To the Editor of THE LANCET.

SIR,—In your last issue Dr. Shorthouse expresses himself utterly astonished at your statement as to the more frequent use of the forceps in midwifery practice, and asks for some obstetric authority to support it. Will one quotation suffice to lead him into fresher fields of inquiry? On the first page of Dr. Playfair's second volume on the science of midwifery, he will find these words:—"Less than thirty years ago the forceps were not used more than once in 310 labours, while, according to the report for 1873, the late master (Rotunda Lying-in Hospital) applied them once in eight labours."

In the later volumes of the Dublin Obstetrical Society he will find ample corroboration of your assertions and also in a report of the discussion in the London Obstetrical Society, published in THE LANCET, vol. i., 1879, p. 689 *et seq.*, and vol. ii., p. 93.

I am, Sir, yours obediently,

Cambridge, October 4th, 1882.

ROBT. N. INGLE.

*Medical Etiquette.*—The advertiser and the advertisement are alike beneath notice.

R. H.—We know nothing of the case or of the person named.

## INTRA-VEINUS INJECTION OF FLUID IN SEVERE HÆMORRHAGE.

To the Editor of THE LANCET.

SIR,—Transfusion is, under ordinary circumstances, impossible, and we must all welcome the substitution of a practicable operation. Dr. Jennings's plan (particulars of which appeared in your last issue) might be still further simplified by using as an injection water with salt and brandy, and having a cannula which could be fitted to the common obstetric syringe.—I am, Sir, yours faithfully,

Leeds, Oct. 2nd, 1882.

PHILIP FOSTER, M.D.

## STATISTICS OF SUICIDE IN PRUSSIA.

ACCORDING to details from official sources which have recently been published in the German press, suicide is on the increase in Prussia, the annual proportion of self-inflicted deaths per 100,000 of population having risen from 13 in 1880 to 18 in 1880. The manner in which these suicides are carried out does not seem to have varied much, with the exception of a greater preponderance of poisoning amongst the female cases. May, June, and July are the months most fatal in this respect. The number of suicides in each period of human life seems to increase with more or less regularity until the stage between fifty and sixty years of age is reached, which shows the highest proportion. There is an excess of deaths shown for the period between twenty and twenty-five years of age; still it does not alter the general fact as to the later portion of middle-age showing the most cases of suicide.

*M. D. Edin.*—The cases are somewhat different. The Edinburgh College of Physicians has lately determined that an examination shall be passed by candidates for the membership, except in certain cases. Only members of one year's standing are eligible as Fellows, who are elected by ballot. In the College of Physicians of London, too, members only are eligible to the Fellowship, and members are elected after examination. Here also the appointment of Fellows is rather a process of selection than of election.

## "THE POSITIVE OR RATIONAL TREATMENT OF GONORRHOEA."

To the Editor of THE LANCET.

SIR,—In reply to the kindly notice of my letter on the above subject by "C. H. W.," with a request for further information, allow me to say that, regarding as I do this ailment as an inflammation due to specific causes for which there are specific remedies, I know of no earthly reason why, excepting those to which I will here briefly allude, its cure should not be reasonably expected and effected within such limits of time as are demanded for the cutting short and treatment of simple ophthalmia, &c., these several drawbacks being—1st, the heastly and objectionable character of the medicines given, which effectually sicken the patient, and make him dread and refuse to take the remedies with that perfect regularity which is absolutely and essentially necessary to its early subdual; 2nd, the utter want of sympathy manifested by most practitioners with young patients when they happen to have got into trouble of this character—a sort of holding aloof from them, which folly has the undoubted effect of driving them into the hands of druggists and advertising quacks, who lose no opportunity of cultivating the impression that medical men do not understand this class of ailment; 3rd, the not unfrequent want of means to meet the high charges in ready money demanded by medical men (who very properly decline to allow accounts to run on with men who, being as a rule unmarried, have no settled home, and thus offer no security for payment); whilst, 4th, there always exists the possession of a consciousness that in going to the doctor they may be recognised or watched—a suspicion which haunts them, and not unfrequently deters them from that steady perseverance which is so absolute a necessity if early cure is to be expected or effected. From long experience I am certain that a single dose of medicine missed is actually detrimental to an early cure; the late Dr. Peatson, of the Manchester Lock Hospital, seldom or never failing to cut the ailment short by drachm-doses of fresh cubebs given in cold water every three hours of the waking day, and this entirely without the use of any injections. Finely ground cubebs are not very objectionable to take, excepting for their bulk, being infinitely preferable to the smallest dose of balsam or any other preparation with which I am acquainted, the much belauded alkaline solutions of balsam, buchu, &c., being enough to turn the stomach of the typical horse of which we hear so much, and certainly expensive boilings and distillations, against the purchase or use of which, from practical experience, I would warn my brethren. Now, whenever gonorrhoea patients come to me, I distinctly give them to understand that I will not undertake their cases unless they are prepared to take a bottle of medicine daily for at least two or three weeks. For this course I kindly, but firmly, give them my reasons, not the least of which are that, having before they came to me been under treatment (for medical men seldom get these cases at first hand), I will not allow them to play with me as they have done with my predecessors, nor will I give them room after a certain time of desultory trial with me to go away and tell "some other man" I cannot cure them, whilst the fault of non-cure lies entirely with themselves. For the rest, I try to give them confidence, enter into sympathy with them, arrange the method of fetching the medicine, try to meet their circumstances of payment, and thus, in ordinary cases, never fail in shortly proving to them by their steady improvement the absolute certainty of a speedy cessation of the discharge, scalding, and other evidences of an existent inflammation, which surely yield to those common-sense remedies which patients have a right to expect from the youngest qualified practitioner.

And now as to treatment. I always recommend the wrapping round the glans penis an inch wide piece of lint several inches long, held lightly on with thread, which lint I order to be kept constantly wet with cold water. This usually prevents sensitive erections, and the pain attendant on the chordee, which is so much to be dreaded. For my empiric recommendation of five grain doses of the iodide of potash, all I can say is that, besides its solvent influence on the essential elements of the powder, I can but further refer my brethren to its well-recognised

action on the various mucous surfaces, as evidenced by the discharges to be noticed very frequently from the nostrils, eyes, &c., when exhibited for rheumatism, &c.; but whatever its action in combination with full doses of cubebs, I believe it to be simply invaluable in subduing and killing the poison of gonorrhoea, and this I assert after a very extended experience of its use. Personally I do not believe that any number of cases of this ailment occurring to the same patient have the slightest influence over each other. Each case stands simply on its own merits, each one being due to the contact of fresh poison. A cure is a cure, and there is an end to the business. Protracted cases are neglected cases. A patient may have it twenty-eight days, twenty-eight weeks, or twenty-eight months, just accordingly as he proceeds to get rid of it.

With regard to your correspondent's inquiry as to whether gleet is contagious or not, I answer if gleet is, as I understand it to be, a thin, sanious discharge left after a protracted gonorrhoea—such slight discharge as is to be noticed occasionally and especially in a morning—then undoubtedly it is; and a medical man does a most monstrous thing when he recommends or allows a patient to marry or have coition with his wife while the slightest trace of any such discharge exists.

I am, Sir, yours, &c.,

TROCAR.

Sept. 27th, 1882.

*Mr. Guesdon.*—We are not aware. Probably the information may be obtained from the publisher of the book mentioned.

*Auld Reekie.*—The papers, we believe, are not published, and can be obtained only through private sources.

*Mr. John Gill's* (Bangor) communication arrived too late for insertion in our present number. It shall receive attention next week.

*Mr. Robert Jones's* cases will be published shortly.

## BELLADONNA POISONING.

To the Editor of THE LANCET.

SIR,—A few notes of a case of this nature, which occurred in my practice lately, may be worth recording.

A little boy, four years of age, drank part of a solution of extract of belladonna, which was being used by his father for an affection of the eye; I could not ascertain exactly the strength of the lotion, but was told that a piece of the extract, "about the size of a bean, was dissolved in a little hot water." I first saw the child at 4 P.M., an hour after the poison had been taken; he then presented no unusual appearance, except a little suffusion of the eyes and restlessness. An emetic had already been given, followed, after vomiting subsided, by a strong aperient. At 8 o'clock I saw him again. He now showed rather alarming symptoms; the pupils were dilated, the face, upper part of chest, and ankles were congested and swollen, he had slight delirium and frequently recurring convulsions, the tongue and mouth were parched, and the temperature was high. A warm bath was ordered and small doses of brandy. I next saw him at 9.30, when all the symptoms were aggravated except the convulsions, which were not so strong; the pupils had now become completely dilated, delirium increased, and the whole body was intensely red and tumefied. Earlier in the evening one dose of opium had been given, but I now resolved to put the boy under the influence of the drug; with this view, three minims of tincture of opium were given every quarter of an hour for two hours. At 12 o'clock the convulsions had almost ceased, the delirium had somewhat abated, and the pupils were less dilated, but not contracted; the child was now becoming drowsy and shortly afterwards slept; the sleep being quiet and the breathing free, he was left undisturbed. At 5 A.M. he woke up, asked for water to drink, and again dozed off to sleep. When I saw him at 9 he appeared well, but still a little drowsy. In the evening he had completely recovered and was running about the room.

I am, Sir, yours truly,

J. D. MILLER, M.B. Edin.

St. Anne's-road, Notting-hill, W.

*Mr. T. Richardson.*—The College of Physicians and Surgeons of New York is above reproach.

*Mr. Arthur Price.*—Our correspondent had better make application to the Secretary to the Post Office.

*Dr. James Nicholls.*—The subject is referred to in another column.

## "MORPHIA POISONING BY HYPODERMIC INJECTION."

To the Editor of THE LANCET.

SIR,—I read with great interest Mr. Hill's case of the above. It will be seen from the account of the case that the patient was suffering from cardiac disease. I have always used morphia subcutaneously with great caution in cardiac cases, as I believe such patients are very susceptible to its influence, and this case would seem to corroborate the idea. I have certainly seen one-sixth of a grain of morphia subcutaneously produce considerable drowsiness. In cardiac dyspnoea I have found one-twelfth of a grain of morphia subcutaneously relieve the symptoms and give a night's rest, and do not like to give a larger dose.

I am, Sir, yours faithfully,

M.D.

Oct. 2nd, 1882.

To the Editor of THE LANCET.

SIR,—In reference to the case published by Mr. Hill in THE LANCET of last week, may not an explanation of the evil effect of the administration of an opiate be found in the pathological changes in the kidneys which are usually associated with valvular disease of long standing?

I am, Sir, yours truly,

Heckmondwike, Oct. 2nd, 1882.

JAMES TURTON, M.R.C.S.

## THE TYPHOID OUTBREAK AT DRYSDALE, AUSTRALIA.

DR. J. G. CARSTAIRS, medical officer of health for Billaraine shire, has reported to the local board on this epidemic. The report, as it appears in the *Australian Medical Journal*, is brief, but states the investigation to have been careful and minute. All the ordinary causes of typhoid outbreaks having, in the opinion of the reporter, been excluded, he concludes there was "ample cause for its appearance in the season," which has been exceptionally hot and dry, and marked by sudden alternations of temperature.

W. F.—As far as we know, no observations on the boiling point of milk have been recorded. No doubt it varies with the composition of the milk. The only temperature that could be observed would be the point at which the boiling commenced. The thermometer would of course rise as evaporation went on.

## "TREATMENT OF EPILEPSY."

To the Editor of THE LANCET.

SIR,—In reply to your correspondent, "Alpha," I can advise him from personal knowledge to try the treatment of epilepsy recommended by Professor Ball of Paris. It consists of the simultaneous administration of the bromides, with oxide of zinc and belladonna.

The formulae are as follows:—1. Bromide of sodium and bromide of ammonium, of each ten grammes; water, 300 grammes. Begin by taking four tablespoonfuls daily in an infusion of valerian, and increase to eight or ten daily. 2. Extract of belladonna and oxide of zinc, of each one gramme. Make forty pills, of which two are to be taken daily. In obstinate cases they may be increased to four. 3. A drastic purge once a week.

Two years since I was asked by a lady to prescribe for her nephew in Algeria, whose father had forwarded a very clear description of his son's case, wishing for further advice. Four epileptic attacks of a most unmistakable character had occurred within the previous three months, the last one being followed by heavy sleep and subsequent prostration. In the opinion of the local practitioner the attacks were due to an "excess of health;" he considered that the young man (age nineteen) had *tropé de santé*, and recommended marriage as a fit and proper exortory. I am at a loss to conceive upon what grounds he based this theory, for it was expressly stated in the father's report that the patient was perfectly free from any vicious proclivity. It is almost needless to say that I put my veto upon the matrimonial project. The medicinal part of the treatment prescribed was comprised in the preceding formulae, and this was supplemented by a few hygienic and dietetic suggestions. Ten months later the same lady called to tell me that the treatment had been completely successful, the patient having been entirely free from any recurrence of his malady.

I may mention that I submitted the father's report quite recently to Professor Ball, who agreed with me that it was an undoubted case of epilepsy. Should your correspondent think it worth his while to pursue the subject further, he will find it fully developed in a recent Paris thesis by Dr. G. Boyé, on the Treatment of Epilepsy, and also in Nos. 1 and 3 of *L'Encéphale* for 1881.

Two other plans have been recently recommended, but with these I have no personal acquaintance. The first consists of the subcutaneous injection of curare. Dr. Kunze has so treated thirty-five cases with nine successful results. The solution used is—curare, fifty centigrammes; distilled water, five grammes; hydrochloric acid, one drop; one-third to two-fifths of a syringe-full to be injected every fifth day. The second is the ligature of the vertebral arteries as practised by Dr. W. Alexander, who contributes a paper on the subject to the last number of *Brain*. The thirteen cases related in the periodical, and in an article which appeared in the *Medical Times and Gazette*, Nov. 19th, 1881, are certainly most encouraging.

To conclude, I would refer "Alpha" to Dr. Gowers' monograph on Epilepsy. It is by far the best treatise on the subject of modern date.

I am, Sir, yours obediently,

Paris, October 2nd, 1882.

OSCAR JENNINGS, M.D.

To the Editor of THE LANCET.

SIR,—I beg to reply to your correspondent, "Alpha," who seeks for information relative to the treatment of others who have had experience in cases of epilepsy.

I have had not a few persons under my care suffering from that malady. I have found chloral hydrate in combination with either bromide of potassium or bromide of ammonium the very best line of treatment. It is advisable to vary the treatment by substituting occasionally for the chloral a mixture of belladonna with spirits of ammoniated valerian and tincture of lavender, or solution of strychnine, spirits of chloroform, and quinine, more especially if the patient shows symptoms of debility and loss of muscular power. The bromides must then be stopped for a period. Of course the secretions must be attended to, diet, &c., and moderate exercise and very little, if any, stimulants. I have a gentleman now under my charge who had epileptic convulsions a short time back, requiring six people to hold him, which I stopped by injecting morphia, &c., into his arm. Another man of powerful build and constitution I had to give 170 grains of chloral in thirty-six hours before I could arrest the fits and procure sleep. After six hours continued rest he woke up quite restored. The treatment was somewhat heroic and caused me much anxiety, and I would not care to repeat it, but trust to the atropia capsules and morphia.

I am, Sir, yours faithfully,

Sarratt House, Sarratt, Oct. 3rd, 1882.

J. WRIXON.

## THE F.R.C.S. EDIN.

A CORRESPONDENT, who is pleased to sign himself *L.R.C.S. Ed.*, has chivalrously undertaken to defend the practice followed by the authorities of his College of selling their diploma of Fellow. He has doubtless eased himself by penning his lucubration, in which such choice expressions as "intense hatred of Edinburgh," "to throw dirt at the Edinburgh Corporations," "paltry gossip," "cockney minds," "the jealousy of London, a city where the art of teaching is simply unknown," give piquancy to what would otherwise be a silly tirade of abuse, misrepresentation, and error. It is needless to pursue the matter further.

## COTTAGE HOSPITALS IN AMERICA.

DR. C. A. HART, of Plainfield, New Jersey, in a communication to the *New York Medical Record*, claims the distinction of being a pioneer in the cottage hospital movement in the States for the Mecklenburg Hospital of Plainfield. The building, says Dr. Hart, combines the latest known advances in hospital architecture, accommodating twenty-five patients. The cost of the building was about 5000 dollars.

*Enquirer*.—Even under the circumstances it would be an unseemly thing for a practitioner to apply for appointments held by another medical man.

## "A DISAGREEABLE DUTY."

To the Editor of THE LANCET.

SIR,—Mr. Wise's letter in your last issue makes charges of intentional and ostentatious discourtesy against me, in my capacity as house-surgeon, which are, to say the least, inaccurate.

I did my duty to the patient and listened much more politely to Mr. Wise's opinion than either his manner to me, the professional knowledge he displayed, or the qualifications he possesses would call for. Mr. Wise is not registered and his name does not appear in the Medical Directory, and though he signs himself M.D., he can scarcely expect to be considered a brother professional. Mr. Wise ought to have presented his card, and should certainly have had the politeness to remove his hat instead of wearing it the whole time he was in the hospital.

The patient was suffering from an incised wound of the forearm, dividing the ulnar artery, which was quite superficial, and should have been secured by Mr. Wise at once. The radial was not injured, as he asserted in our receiving-room, and it certainly was not then and has not since become necessary to amputate the limb, as suggested at the time by him.

Mr. Wise has omitted to state that I offered that he should accompany the patient into the ward, and that, should he desire to watch the case, he would be very welcome to do so. I need scarcely add that no one at this hospital would willingly be discourteous to anyone.

I am, Sir, yours, &c.,

London Hospital, E., Oct. 3rd, 1882. R. HINGSTON, M.R.C.S., &c.

*Students* has not enclosed his card.

*Mr. Mussey*.—It would be contrary to our rule.

*Mr. Donald McAlister*.—The suggestion shall have attention.

## THE EFFECT OF LIGHT IN AIDING SNEEZING.

To the Editor of THE LANCET.

SIR,—For many years past I have noticed that when I feel that uncomfortable sensation of wanting to sneeze and not being able to, I have only to go to the light and look at a bright sky or white cloud, or, best of all, the sun, and the effect is magical in producing a comfortable sneeze. I never take snuff. I have noticed this effect of light in inducing sneezing in other people. Can you explain its action?

I am, Sir, yours, &c.,

Sept. 28th, 1882.

A LAYMAN.

*Scrutator*.—We cannot express an opinion on conduct, of the motives for which we are so uninformed as in this case. A bare statement of the facts might be inserted.

*T. C. D.*.—No card enclosed.

## THE CONTAGIOUS DISEASES ACTS.

To the Editor of THE LANCET.

SIR,—Would it not be a good thing if some of your chief medical authorities on this question were to invite the clergy to a conference, or to hear papers read upon this subject? I believe the majority of my clerical brethren know little or nothing of the aim and objects of the Contagious Diseases Acts, and that if they did know more about them they would, with you, advocate their extension.

I am, Sir, yours truly,

Margaret-street, W., Sept. 30th, 1882.

ARTHUR BRINCKMAN.

*Mr. A. E. W. Cason*.—Apothecary.

*C. Y. B.*.—1. No.—2. We are not aware.

## CARFERAL.

To the Editor of THE LANCET.

SIR,—Will you or any of your subscribers kindly give me some information about the Netley filtering medium, Carferal? Where is it to be obtained, at what price, and what is the best mode of using it?

I am, Sir, yours faithfully,

Chiswick, Oct. 2nd, 1882.

ÆSCULAPIUS.

### Medical Diary for the ensuing Week.

## An Address ON THE ANTISEPTIC TREATMENT OF DISEASES OF THE LUNGS.

*Delivered at the Inaugural Meeting of the West London  
Medico-Chirurgical Society.*

By I. BURNEY YEO, M.D., F.R.C.P.,  
PHYSICIAN TO KING'S COLLEGE HOSPITAL ETC.

GENTLEMEN,—When your secretary, Mr. Keetley, did me the honour of inviting me to bring before this Society the subject of the Antiseptic Treatment of Pulmonary Diseases, I confess I at first hesitated to accept that invitation. I felt that although I had given some attention to the subject, my time was at this moment so fully occupied, that I should not be able to deal with the subject so fully and completely as its importance merited, or as was due to a Society so learned and influential as yours. I also felt that it was a subject which was only just beginning to be looked at from something like a firm scientific standpoint, and that from this point of view the question of the antiseptic treatment of diseases of the lungs was in its initial stage, a stage certainly full of suggestions for future investigation, but the work of examination, of experiment, of comparison, of testing, and of criticism—serious, helpful criticism,—for the most part had yet to be gone through. It might then, I thought, seem premature to introduce this subject to this Society for discussion in its present stage; but when I reflected on the intrinsic importance of the subject itself, when I thought of the vast interests, direct and collateral, involved in its discussion, and of the power and influence the members of such a Society as this would possess in collecting evidence bearing upon it, I yielded to your secretary's request, relying on your kind indulgence to excuse the merely suggestive character of this address and the many shortcomings and defects which future research alone can supply. It is remarkable when we begin to look into the history of almost any subject, how little there is that is new in its facts and its phenomena. What is new resides in our mode of regarding them, our comprehension of them, our application of them. The truth is always there in the facts and phenomena of Nature, but it is often only discovered after ages of observation, of experiment, and of opposition. Of opposition: how remarkable is this spirit of opposition! how remarkable has it been in the history of one of the latest and greatest triumphs and discoveries in the art and science of surgery, the antiseptic system. As if the work of discovering truth in this universe was not hard enough, men are perpetually encountering from their fellow-men the most ardent opposition in this task. In proof of what I say I need only point to the present agitation on the part of a well-known Society against all experiments on animals—a Society which, reversing the exclamation of the dying Goethe for "more light," might be fittingly designated "The Society for the Maintenance of Darkness."

The idea of an antiseptic treatment of pulmonary diseases is certainly new in our present mode of regarding it, in our comprehension of the phenomena with which it is concerned, and in the extended application which we propose to give to it. But the thing itself is not new, the phenomena are not new. The adoption and the success of antiseptic methods of treatment of pulmonary affections have been recorded again and again, and they have, again and again, met with opposition, and not rarely with a sort of sneering contempt. This, gentlemen, you may be satisfied will never be the case again, and for the following reason. Hitherto, or till quite lately, such efforts were empirical, and without any strictly scientific basis, but now our antiseptic methods are founded on scientific knowledge—on principles, principles that have been evolved from a series of most patient and at the same time most fruitful investigations, which will go far to make this latter half of the nineteenth century the most illustrious in the history of medical science. A very few historical illustrations will suffice to prove what I have said about the antiquity of the fact of the antiseptic

No. 3085

treatment of pulmonary affections. Hippocrates and Galen used to advise the inhalation of balsamic vapours in pulmonary affections, and the latter used to recommend phthisical patients to settle in the vicinity of Vesuvius and Etna, where they could inhale sulphurous vapours as well as sea air. But we will confine ourselves to the history of pulmonary therapeutics during the last hundred years, and one of the most noticeable facts in this period is the frequency with which tar vapour has been advocated as of great value in the treatment of lung diseases. Dr. Rush of Philadelphia in 1787, Dr. Beddoe in this country about the same time, and Sir Alexander Crichton in 1817, all stated that they had met with great success in treating cases of phthisis by inhalation of the vapour of boiling tar, and Dr. Solis Cohen, in his excellent book on "Inhalations" in connexion with this testimony, says: "The use of tar vapours in phthisis deserves to be fully and systematically studied, so that safe indications may be laid down as to the character of cases to which it is most applicable." Between 1819 and 1830 the French physicians Gannal and Cottereau, and Sir James Murray in this country, reported excellent results from the treatment of cases of phthisis with dilute chlorine vapour. One of these had noticed that the workmen in bleaching factories with chest disease visibly improved, and another reported thirteen cases of phthisis cured by inhalation of chlorine, and Louis in Paris, and Dr. Elliotson and A. T. Thompson in London, spoke well of it.

In 1835 Sir Chas. Scudamore became an enthusiastic advocate for the inhalation of iodine vapours in phthisis, and after ten years' experience of its use he expressed himself as convinced of its remedial power. Piorry (between 1850 and 1860) also was an advocate for the continuous inhalation of iodine vapour in phthisis, and for this purpose he used to have several saucers containing iodine placed about the patient's pillow. He treated thirty-one patients in this way for two years; twenty were decidedly benefited, both as regards symptoms and physical signs; in seven cases both symptoms and physical signs disappeared, and four cases died. Later still Skoda used inhalations of the vapour of turpentine with much success in phthisis, pulmonary gangrene, and in catarrhal affections of the air passages.

I have selected these few illustrations almost at random from the history of pulmonary therapeutics to prove to you that I was right in saying that there is nothing new in the facts, and they also go towards disproving the statement that I have lately seen made by one or two writers in the journals of the small amount of success that has attended the antiseptic treatment of phthisis.<sup>1</sup> I suppose I have as much right to speak on this subject as any of those writers, for during ten years I saw personally over 27,000 applicants in a hospital devoted to the treatment of this affection, and of all the methods of treatment of which I have had any knowledge or experience, those into which some antiseptic measure entered as an important element were certainly attended with the best results. The difficulty, however, always was to secure anything like a proper application of an antiseptic agent; and after trying various devices for this purpose, I at length devised a very simple method of continuous inhalation, which answers the purpose better than any other with which I am acquainted. I have described this elsewhere,<sup>2</sup> and you can examine the specimens of the little apparatus I have devised for this purpose that are on the table.

Let me here make a remark which as practical men you will at once see the force of. It is useless to attempt to test any method of treatment by applying it to cases of advanced phthisis. In such cases the mischief is done. No antiseptic agent will cause numerous suppurating cavities to close up and heal, or replace lung tissue that has been destroyed by progressive ulceration and disintegration, or remove extensively disseminated tubercular and inflammatory infiltrations. And yet how many cases of phthisis come before us already in this state. It is greatly to be regretted that certain physicians should ever have pretended to have cured such cases, and that others should seriously have tested their statements by the application of any special method of treatment to cases so advanced and so hopeless. In order that any case may be cured by any method of treatment the first and essential condition is that it should be curable. And cases of phthisis too often come for the first time under our observation long after the possibility of cure is passed.

<sup>1</sup> In my recently published Lectures on Consumption I have collected a mass of contemporary testimony in favour of this treatment.

<sup>2</sup> Lectures on Consumption. London: J. & A. Churchill.

But the question for us to examine and to satisfy ourselves about now is this, Is an antiseptic system of treatment applied to lung diseases true in principle? If we can convince ourselves that the principle is a true one, modes of application and developments in practice will be certain to follow. In the first place, then, let us inquire, What is antiseptic treatment? Antiseptic treatment applied to the lungs is one or both of two things: First, it is the prevention of a hurtful, poisonous (septic) agent getting to the lungs from without; and, secondly, it is the destruction, or the limitation of the action of a hurtful poisonous (septic) agent already within them.

And now let us ask ourselves if there is any *a priori* reason why it should not be possible to satisfy both these indications. It was argued warmly not many years ago, as a necessary preliminary to this discussion, that it was impossible to bring medicinal agents into contact with the pulmonary surface by inhalation. That argument has been abundantly disproved by the most varied and elaborate experimental investigations.<sup>3</sup>

So, then, supposing a hurtful septic agent to exist in the lungs—and in phthisis the presence of such an agent has been demonstrated beyond all question, and its virulently septic quality established—the problem of the antiseptic treatment is this: Do we possess, or can we discover, any agent which we can convey, in the form of gas, vapour, or solution into the lungs which shall be inimical to the life and activity of this septic body? Or can we place our patient under any possible conditions of life which shall prove hostile to its growth and development? It would be illogical and absurd in the extreme to deny the possibility of such a method, or of the discovery of such an antiseptic agent, if we do not already possess one or more. The second indication must therefore be admitted to be quite possible. Now, let us turn to the first indication. It is not only necessary to destroy any septic agent that may be already in the lungs, but we must be able to prevent septic agents from entering them with the respired air. Now, this may be accomplished in two ways: (1) We may place our patient in an atmosphere which by examination we know to be absolutely pure and free from septic particles; or (2) we may diffuse through the air he breathes an agent hostile to the life and activity of any septic particles there may be in it. This, again, is a true antiseptic treatment, and it is certainly possible in either of these two forms. If then we limit ourselves (which we had better do on this occasion) to the consideration of the treatment of phthisis, we have two things satisfactorily proved. First, there does exist a hurtful specific septic agent in the lungs. Second, an antiseptic treatment is possible. There is no beating the air in this. Gentlemen, we are here on sure and certain footing; we have reached a principle. This is only the first stone of the edifice we have to build, but it is the foundation stone. The next thing for us to do is, by patient labour in the way of observation and experiment, to apply this principle. Our object is to discover what agents there may be within our reach capable of being administered without inflicting injury to the pulmonary tissues, which may have the power of destroying, or neutralising, or arresting the activity of the septic organism, which seems to be the operative cause in the origin and propagation of phthisis. I am disposed to believe that other common forms of disease of the respiratory organs have a septic origin also, and call for antiseptic treatment, but we must for the present concentrate our attention on this subject of phthisis.

Already we have abundant and incontestable proof that pure air—pure, cool dry air, in unlimited amount—is such an antiseptic agent. Wherever such air is found—on the high table-land of Mexico, in the elevated valleys of Switzerland, on the Kirghiz steppes of Asiatic Russia, in the pine forests of Central Germany, and on the open sea—wherever men live a life in the open air, away from the emanations of cities, and from too close contact with humanity,—in all such places we hear of consumption becoming arrested and cured. The bacillus tuberculosis seems to love hot, moist air, and air freely charged with the exhalations of humanity; warmth and moisture seem to provoke it into special activity, while dry air at a comparatively low temperature seems to be inimical to it. Whoever has watched, as I have done, a large number of cases of phthisis in this country, must have been struck with the frequent occurrence of rapid advances

in the disease during the first warm moist days of spring and early summer.

And here again I am tempted to quote a passage to which my attention has been recently called by my friend, Dr. Frank of Cannes, to show how true it is that the facts we are discussing are not new. It occurs in a very able book by a German writer, "Hausrath on New Testament Times," an English translation of which has been published by Williams and Norgate. He is alluding to the mountain air of the fortress of Masada, a mountain fortress on the borders of the Dead Sea, where John the Baptist was imprisoned. There, he says, Josephus tells us provisions retained their freshness for over 100 years "because the air at the altitude of the fortress was purified from all earthly and corrupt particles!" It is precisely such air—air purified from all "corrupt particles"—that we require for our phthisical patients; and if we cannot send them where such air is naturally found, we must artificially create for them an antiseptic atmosphere which they can breathe where they are; and if we are to perpetuate consumption hospitals, it is with such an atmosphere we must fill them. But the time will probably come when instead of crowding a number of consumptive patients together in the centre of a populous district of a crowded city, we shall acquire for the same purpose a good-sized pine wood with a dry subsoil a few hundred feet above the sea-level, and build a certain number of scattered cottages through the wood, and hang up a number of hammocks between the fir trees and send our consumptive patients there to be aired into health! In wet weather they would make up fires of fir wood and pine cones, and so fill their cottages with balsamic and antiseptic vapours; and with open windows and a dry soil they would find the wet weather less injurious to them there than in towns. But we have other antiseptic resources more manageable than a pine wood. And here let me call your attention to the peculiar anatomical conditions of the respiratory organs, by which they are rendered peculiarly prone to septic attack, and specially needing of antiseptic defence. The lung is the only deep-seated internal organ in the body which is freely accessible to the surrounding air. Perpetually the outer air is passing in and out of the lung, and thus septic particles in the air can readily reach the pulmonary surface, which is most richly supplied with absorbent vessels. But if, owing to the anatomical disposition of the parts of the lung septic bodies can readily reach it from without, for the same reason antiseptic particles can also be readily brought into contact with it, either in the form of gas, or vapour, or fine spray and mist, or even fine solid particles.

It is needless to offer you any proof of this. You will, I take it, all accept this statement as proved; and you are no doubt familiar with various forms of apparatus devised for the purpose of carrying out such applications. But though we may sterilise or destroy in this way such germs or microbes as may commonly occur in the surrounding atmosphere, and so purify and render harmless the air that passes in and out of the lungs in respiration, it does not follow that the agents we now know to be germicides, such as carbolic acid, eucalyptol, thymol, &c., and which are used by surgeons on account of that property, are necessarily destructive of the tubercle bacillus. Analogy would lead us to conclude they might be, and the experience of their use in the hands of many competent observers,<sup>4</sup> tends to strengthen this view. But we must not rest satisfied with this; we must pursue our studies of the life-history of the tubercle bacillus until we have discovered what is the particular agent or agents which are especially inimical to its development and activity.

There is another difficulty which we must be prepared to encounter—the difficulty of inducing patients to submit to a continuous process of disinfection. It is by no means easy to induce phthisical patients to wear, almost continuously, even so light and simple an appliance as the one I have shown you, and it would be infinitely more difficult to get them to inhale a spray for many hours a day, supposing it should be discovered that the best antiseptic is soluble in water but not vapourisable at ordinary temperatures, as was the case with the benzoate of soda of which so much was expected by some. But I believe this difficulty would almost entirely disappear if our knowledge became absolutely precise, and our confidence in our remedy completely assured. If we could say to our patients "by this means you will be cured,

<sup>3</sup> Vide Oertel: Respirator'schen Therapie.

<sup>4</sup> Lectures on Consumption, Appendix to Lecture 2.

and by no other," this difficulty would, I am persuaded, almost cease to exist. Hence, however, we see the obvious advantage of being able to remove our patients to an antiseptic atmosphere where they cannot help inhaling the curative agent continuously.

And now I must bring these merely suggestive observations to a close. In the foregoing remarks I have chiefly endeavoured to show that the idea of an antiseptic treatment of lung diseases is based on scientific data, and that in principle it is established as a truth. What lies before us is to overcome the difficulties in its application. We should be encouraged in this work by the thought that whatever progress we are enabled to make we shall be furthering the labours of the great experimental pathologists of our times, the labours of men like Pasteur, Koch, and Lister. It is not given to everyone to be enabled to work with a genius and an energy like theirs. But let me remind you that one of them—Koch—was a country doctor, a general practitioner, like many who are here to-night; and we may all do something towards transferring the influence of their intelligence and their genius, and in applying the fruits of their labours to the practical daily duty of healing the sick; and in spite of much disingenuous misinterpretation and foolish abuse we may be able to prove to the world that experimental pathology is in the very highest degree beneficent and philanthropic. For the first time we seem to have grasped a principle in the treatment, both preventive and curative, of a class of diseases which we have hitherto regarded almost with despair. Let us steadily work on the foundation which this principle supplies, the successful application of which must be attended with immense service to humanity and lasting honour to medical science.

## Introductory Address

DELIVERED AT

UNIVERSITY COLLEGE, LONDON,

*On the Opening of the Winter Session of 1882.*

By MARCUS BECK, M.S., F.R.C.S.

*(Concluded from page 561.)*

THUS, then, we have a large number of our students started on their medical education badly, and the consequence is that they spend a great part of their first year of study in learning how to learn, and doing that imperfectly. From want of training in generalisation and classification, their knowledge consists merely of a mass of disconnected details, and the strain upon the memory becomes correspondingly great. A thorough and clear comprehension of a subject is essential for its easy acquirement; and without some knowledge of chemistry and physics it is impossible to understand a great part not only of physiology, but of medicine and surgery also. The evil habit of thought which is cultivated by this irregular training in the early part of study frequently persists throughout the whole course, and the difficulty experienced by the student in passing the primary examination is exaggerated in the final, as that includes no subject like anatomy, in which mere memory is of more value than logical thought.

In order to obtain a double qualification, however, the student has to present himself for this examination at the College of Physicians or the Apothecaries' Hall, and it is very common for this to be done after the College of Surgeons is finished. Consequently we often find him preparing for examination in chemistry and botany some two or three years after he attended the classes on these subjects, and at a time when it is too late for him to derive that mental training from them which should have assisted him in his course of study. Some effort to remedy this evil has of late been made by the College of Physicians by the institution of the new examination to be passed at any time after registration. This, no doubt, is a step in the right direction, in so far as it encourages the student to pass his chemistry and botany at as early a period as possible of his medical study. But, on the other hand, it seems to be specially designed to encourage him to spend some time in a sort of modified

apprenticeship before commencing his work at a medical school. Now if the object were to re-establish the old prescribing druggist, as he was before the apothecary developed into the general practitioner, nothing could be better; but if the future licentiates of the College of Physicians are to be educated as men of science, the introduction of a period of desultory work without any proper teaching between school and college can do nothing but harm. The botany also, which he is to learn, is defined as medical botany. Now the only justification for retaining botany in the early part of a medical curriculum is, that of all subjects it gives the best training in the accurate observation of simple facts and in classification, and unless it is taught as a science with this object, quite irrespective of its supposed utility in medicine, it might just as well be omitted altogether. Although, therefore, the examination is doubtless a relief to the student, by enabling him to get rid of some troublesome subjects during his first year, it is not likely to do much to improve his training from a scientific point of view, and I believe it is only by an improved training that we shall be able to diminish the lamentable proportion of rejections which forms almost a reproach to our medical teaching. Up to the present time, however, the attempt to meet the higher standard required at the examining boards has been chiefly by increased quantity of teaching, and at the same time the mode of teaching has become more practical and demonstrative. At the time I was a student here there were no demonstration classes in anatomy, the class of practical physiology had not been instituted, and there was no class of practical zoology. Voluntary classes in operative surgery and bandaging existed; but the practical surgery class, as we now have it, was not founded till ten years later. At the hospital the only practical instruction given in surgery was the bedside teaching, supplemented by a few clinical lectures, rather theoretical than practical. In the medical wards students wrote reports on cases which were corrected by the professor of clinical medicine, but no classes had been instituted for practical instruction in the rudiments of medical diagnosis. Now we have changed all this, and practical classes crowd upon each other till it becomes almost impossible to find time for them all in the nine hours of the day during which the college and hospital are open. The practical classes in medicine and surgery have no doubt become necessary to replace the teaching that the student formerly received during his apprenticeship; but in other subjects they have been instituted solely with the view of improving the quality of the teaching, and enabling the student to reach the higher standard of knowledge required of him. The result so far, however, has not been to diminish the number of rejections. These still continue in unabated numbers, and will continue, I believe, as long as the present irregular system of education is followed by so large a number of our students. While we expect students to understand the most complicated mechanism in creation without a knowledge of mechanics, to understand the eye and ear without optics or acoustics, or respiration without knowing the laws of atmospheric pressure; while we expect him to understand the chemistry of digestion almost before he knows the difference between an element and a compound, I do not think we can hope for any real improvement in the results of the examinations. It is, I believe, only by a better preparation in science, and by a rearrangement of medical examinations in accordance with the laws of scientific education, so as to train the student to think, and to think well, that we can hope to get any real improvement. To this course, however, many objections have been raised on the grounds that it would add more subjects to the medical curriculum, which, in the opinion of some, already includes more than are necessary; that it would lengthen the period of medical study, and would add another examination to those with which the student is already burdened. Finally, there are some still to be found who deny the utility of science and the value of mental training.

To take these objections in order. First, that it would add another subject to the medical curriculum. I have before said that zoology, although forming an extremely valuable training for those who have time to avail themselves of it, is not essential, and there would be nothing to justify adding it to the ordinary course of medical study. Physics would therefore be the only subject which would be added to those already in the curriculum. Now at the present time, students are expected to know at their examinations all those parts of natural philosophy which apply to physiology, and to the explanation of various morbid

processes both in medicine and surgery. We cannot say therefore that it would be added as a new subject. It would be merely taught methodically, and would prove an assistance to the student in his course of study, rather than an increased difficulty. It is sometimes assumed by those who complain of the number of subjects in the medical curriculum, that the student is expected to learn each thoroughly. To learn any subject thoroughly is the work of a lifetime. All that can be expected from a medical student is, that he shall learn the general principles of the various sciences auxiliary to medicine, and shall attain such an amount of knowledge of each that he shall not be altogether lost when he has to apply them to practical medicine or surgery, and that if necessary he shall know what book to refer to for further information, where to look for what he wants, and when he has found it that he shall be able to understand what he reads. The objection therefore to a scientific course of study, that it increases the number of subjects in the curriculum, seems of but little weight.

With regard to the lengthening of the period of medical study, the objection also is more apparent than real. If the period of study were lengthened from four to five years, it need involve no hardship. The preliminary examination in general education may be, and very frequently is, passed at the age of sixteen. The most difficult of all the entrance examinations, the matriculation at the London University, is passed best by well prepared boys between sixteen and seventeen. Now all those who pass at this age must wait five years before they can obtain a licence to practise. To these, therefore, it would be no hardship to spend a year in the study of the preliminary sciences. Moreover, if it were understood that a year had thus to be spent, it would become the custom to send the candidate up for the entrance examination at the earliest possible age. Of course it is much better that the general education should be continued till seventeen or eighteen, but I am only discussing the case of those to whom it is of importance to gain a legal qualification at the earliest possible time, and for them the luxury of a prolonged general education must be dispensed with. It must not be forgotten in discussing this point, that a very considerable number of students are obliged through misfortunes at their examinations, to lengthen their period of study, sometimes to seven or eight years. The number of these unfortunates will probably in the future be greatly increased by the new regulation of the College of Surgeons, which places a compulsory interval of two years between the primary and the final examinations. To many of these, I believe, a period of compulsory training in science would prove a real assistance in shortening their time of study, by enabling them more easily to acquire the necessary knowledge. And supposing the period of study were actually lengthened by a year, we should still be only returning to the old period of apprenticeship, which lasted five or even seven years. The student himself should, perhaps, be the last to complain of any prolongation of the time of study, for his time at college will probably be the pleasantest part of his life. An examination now and then no doubt forms a hateful incident during its course, but the real troubles of life begin when the last examination is passed. An examination is no great trouble to a student if he is properly prepared for it, and the addition of a simple preliminary examination in science would, I believe, for the reasons I have already given, tend to make it more easy to prepare for those that follow.

Lastly, we have to consider the objections still occasionally raised to the modern system of education, that the value of mental training is more an idea than a reality; that science is of no direct use to the ordinary practitioner; and that, on the contrary, a scientific education tends to make a man unpractical. To deny the value of mental training seems to me to be evidence of want of it on the part of the person who does so. The argument usually employed is that men are to be met with who go through a thorough course of scientific training, and come out at the end as illogical as they began; and, on the other hand, it is not uncommon to meet with those whose scientific education has been defective, and yet whose mental faculties are developed to a high degree. The fallacy of the argument lies first in the assumption that those whose scientific training has been defective would not have been better had their minds been more correctly cultivated; and, secondly, in drawing the general conclusion that training is of no use, from the exceptional cases in which it has failed to produce the desired effect. I feel myself no doubt whatever that those men learn their medicine and surgery more quickly and more thoroughly who have under-

gone a proper preliminary preparation in science. Those who manage to distinguish themselves at examinations, and yet remain illogical and unpractical, are, as far as my experience goes, those possessed of a memory of unusual retentiveness, a faculty which is not necessarily associated with a high order of intelligence. There is, I believe, at the present time a hopeless idiot in Earlswood Asylum who possesses a memory of such extraordinary power that he could, if properly coached, be easily made to take first place in almost any competitive examination.

Of the value of science in the practice of medicine and surgery there can be no doubt. In the first place, to the ordinary practitioner chemistry, and a certain amount of natural philosophy, are essential if he is to undertake intelligently the practice of hygiene—now as important a department as either medicine or surgery. The post of medical officer of health is one, at the present time, open to every medical practitioner, and often furnishes a welcome addition to the somewhat narrow income of the country doctor. In this post he will be expected to undertake the simpler tests for adulterations of food and the purity of water, and he will be required to give advice on questions of ventilation, heating, and warming, and on numberless other subjects in which some knowledge of science is involved. But the innumerable applications of science to modern medicine and surgery are of no less importance. With regard to medicine I would not venture to speak, but I have no hesitation in saying that the wonderful advance which has been made in surgery during the last twenty years has been entirely due to the application to it of science and the scientific methods of investigation. During that period surgery has made more real progress than at any previous time in its history; and this progress has been chiefly due to the discovery of the nature and causes of surgical fever, and of spreading and infective inflammations. It commenced as late as 1866, by the application of Pasteur's discoveries to practical surgery by Mr. Lister. For centuries before this time the necessity of cleanliness in wounds had been well known, and antiseptics had been employed by all surgeons in their treatment down to the early part of this century; but so little were their properties understood, and so doubtful had been the advantages derived from their use, that at the time I was first a dresser in another hospital, twenty years ago, they had been almost completely abandoned, and wounds were treated either by the application of a dry dressing, which was removed when the smell became intolerable, or by placing over them a piece of lint soaked in simple water and frequently changed. Water alone, without the addition of any antiseptic, was used to wash away the discharges. It was only when the discoveries of Pasteur showed us that so-called clean water is in fact one of the dirtiest things in nature, that this treatment was abandoned. Yet while this treatment was being adopted, and it was possible to tell by the smell alone whether you were in a medical or a surgical ward, surgeons were constantly insisting upon cleanliness as the most essential feature in the treatment of wounds, so little idea then existed of what true cleanliness is. Dirt at that time, in the form of putrefying discharges, was considered inevitable; cleanliness consisted in clearing away the decomposing matter: the higher scientific idea of cleanliness, as consisting in the absolute prevention of decomposition, was impossible till Pasteur's discovery had shown to what decomposition is due.

About the same time that Mr. Lister was introducing the antiseptic system of treating wounds, Bergmann and others were, by carefully devised experiments, proving the fact that the high fever which then almost invariably accompanied all large wounds and severe injuries was due to the absorption by the surface of the wound of the chemical products of putrefaction contained in the decomposing discharges. The investigations into inflammation and the allied processes were at the same time establishing as a pathological fact the absolute necessity of an abundant decomposable exudation from the raw surface of a wound during the first few hours after its infliction. To provide a sufficient exit for this discharge by a proper system of drainage became, therefore, an essential feature in the scientific treatment of wounds. Drainage, like the use of antiseptics, was nothing new. Tubes made of metal, and tents of various kinds, were used centuries ago, but, as with the antiseptics, their use was not founded upon scientific principles; and in the anxiety to avoid the introduction of foreign bodies they were completely abandoned, so that twenty years ago such a thing as a drainage-tube in a fresh wound was hardly thought of. Empirical surgery had tried both antiseptics and drainage, and had abandoned

them as useless. Scientific surgery showed their real value, and although the present methods will undoubtedly undergo modification, these two great principles must remain as essential features of every mode of treating wounds. It is to the scientific mode of treating wounds that we owe all the marvellous progress of surgery during the last sixteen years. This progress is not to be judged of by the number of new operations that have been introduced into practical surgery, nor by the heroic nature of some of those recently performed, but rather by the improved results of the common operations, and the greater success that attends the treatment of common injuries.

The study of the unhealthy processes in wounds is still advancing in the hands of Koch and others, but there still remains much to be done. Unfortunately in this country the means of carrying on such investigations are surrounded by so many legal difficulties that we are obliged to trust chiefly to foreigners for new matter, but we can take our share in applying the discoveries of foreign pathologists to the practical treatment of diseases, and to prepare us for this a proper scientific training is a necessity.

That a scientific education tends to make the student unpractical is another argument sometimes used. It is but a poor compliment to our profession to assert that those practise it best who know least about the nature of the diseases they undertake to cure. The complaint as to the want of practical knowledge in the students educated on the modern system comes chiefly from the general practitioner, who asserts that the present student fresh from his college and hospital is of but little use to him as an assistant. If called upon to dispense he is ignorant of how to make his mixtures pleasing to the eye and palate, his pills are too big, his plasters too thick, and the parcels he makes up are badly folded and inelegant, and his knowledge of book-keeping is even more limited than his acquaintance with pharmacy. When a patient has nothing the matter with him he tells him so in so blunt a manner that he immediately seeks out another medical man, who will be a little more sympathetic with regard to his supposed sufferings. He looks upon every patient too much as a case, and fails in all those legitimate arts which are necessary to win the confidence of that most selfish and unreasoning of beings. A still more serious failing often shown by the modern student is, an ignorance of the various infectious diseases which are not admitted into general hospitals. There is no doubt, therefore, that the general practitioner has just cause to complain when asked to give a hundred a year to a man who, however well trained in medical and scientific knowledge, is totally ignorant of the business element which necessarily forms a part of our profession. He finds that he has to pay a man for learning from him that which in the days of apprenticeship he was handsomely paid for teaching. The only remedy for this seems to me to be in the hands of the general practitioner himself. He should refuse to give more than board and lodging to any man who has not had six months' experience of actual practice. Six months of such experience would be quite sufficient, and at the end of that time, I have little doubt, the modern student would practise his profession none the worse for possessing a better knowledge of the principles which guide his treatment.

One advantage of a proper scientific training, to which I have not yet alluded, is that it tends to fit every medical man to take his part in advancing medical knowledge, should he feel the inspiration to do so. The general practitioner is placed in circumstances which enable him to observe certain points in clinical medicine and surgery much better than the consulting physician or surgeon. He sees most of his cases from beginning to end; he can observe those preliminary symptoms which indicate the approach of grave disease; and he has the opportunity of verifying his own conclusions and those of such consulting physicians or surgeons as the patient may have seen. He has unusual opportunities of studying the influence of heredity, of occupation, and of locality on disease, so that, should he feel inclined, he has no lack of opportunity of prosecuting original investigations. A proper scientific training will teach him the method of conducting such investigations, the precautions necessary to avoid error and the utter worthlessness of opinions formed merely as the result of experience, and unsupported by accurately recorded observations. Such original research would be of all the more value, as it would, in most cases, be spontaneous, and undertaken purely from the love of the work, and not, as is so much the case in the present day, merely with the

view to say or do something new in order to obtain promotion either in a hospital or medical school.

Supposing it then to be granted that the best training for every student should include a preliminary education in science, how could such a scheme be carried out? In the first place, it is absolutely necessary that the examinations should correspond to the course of study. Taking sixteen as the age at which a boy could pass his preliminary examination in general education, he could then immediately turn his attention to science. There is no reason why this should not be done before leaving school. At Epsom Royal Medical College students are now prepared for the preliminary scientific examination of the University of London, and there ought to be no difficulty in preparing for a similar examination of a lower standard at any good school. If there were a demand for such education the supply would soon be abundant, and after passing the entrance examination the boy could, if necessary, be moved to some school where the required instruction was given; or, if his parents preferred it, he might at once enter at a college, and enjoy the advantages such institutions naturally possess. The examination in science might take place at seventeen. The subjects of the examination would be chemistry and natural philosophy, and either botany or zoology, or both. After passing this the student could commence regular medical study with a much better chance of making good progress from the very beginning. At the end of the second year, and at the age of nineteen, would follow the examination in anatomy, physiology, and materia medica, and perhaps in applied chemistry, and the remaining subjects at the end of the fourth year of study, when the student had reached the age of twenty-one. Part of his last year of study might doubtless with advantage be spent in receiving instruction from a general practitioner.

There seems nothing impracticable in such a scheme as this, but in order to carry it out it is absolutely necessary that the present disjointed system of examination so often followed, in which some subjects are passed before one examining board, and others before another, should be in some way made impossible. The conjoint scheme does not seem, however, to be as yet within the range of practical politics. The report of the Royal Commission which has just been sitting seems, in the absence of compulsion, to leave us much where we were before. In fact, the idea of a harmonious conjunction between bodies so different in tradition and in character as the University of Oxford and the Society of Apothecaries is, perhaps, somewhat Utopian. It is not, however, necessary for the whole seven licensing bodies of England to conjoin to produce the desired result, so far as the student is concerned. The universities have already expressed a willingness, and are, in fact, empowered to cease giving their graduates a legal right to practise. That they should thus be ready to give up one of their most ancient privileges makes it more to be regretted that they were not equally willing to renounce any direct part in the appointment of examiners, and in the management of the proposed conjoint examination. If the universities retired we should have left, as far as England is concerned, only the three corporations; and it at first seems rather surprising that these three bodies find it so difficult to sink their differences, and unite for the purposes of examination. This surprise will, however, be somewhat lessened if we look back at their history; and it may not be uninteresting to you if, in conclusion, I try, as shortly as possible, to trace how these three bodies have arisen, where we only want one, as I think a review of their history may tend to suggest a remedy for the evil.

In the early part of the reign of Henry VIII. the medical profession consisted of physicians who had received licences to practise both medicine and surgery, either from the bishop of the diocese or from the Universities of Oxford and Cambridge, but who were not united into any corporate body, and of "two several and distinct companies of surgeons, one called the Barbers of London and the other the Surgeons of London," the former having been incorporated as far back as the year 1461. Outside the profession were the apothecaries who kept drug-shops. These were under the control of the Grocers' Company, and had no legal right to practise medicine. In 1518 Henry VIII. granted letters patent, constituting the College of Physicians. From its very foundation it was a body of great dignity and power. The physicians held a social position much higher than the surgeons. Most of them had received an academic education, and were possessed of some degree of culture. The surgeons were as often

as not rude uncultured men, their professional education consisting entirely of an apprenticeship to some freeman of the company of barbers or surgeons. About twelve years after the foundation of the College of Physicians, the two companies of the barbers and surgeons were joined into one; yet curiously enough, any single member of the company was forbidden to practise both the mysteries of barbery and surgery at the same time, unless he was the domestic servant of some great man. This was to prevent their spreading disease, by opening foul abscesses and shaving with the same instruments. The surgeons were kept closely confined to the mechanical part of their art, and if they ventured to order a dose of medicine, they were fined and imprisoned without mercy by the President of the College of Physicians.

For a short time they had, however, the satisfaction of tormenting the apothecaries in their turn, if they ventured to undertake the care of surgical cases. But this happy time for the surgeons was of short duration, for three years after the two companies were joined, an Act was passed, in the preamble of which they were accused of "vexing divers honest persons, as well men as women, whom God had endued with the knowledge of the nature of herbs, roots, and waters;" of "extorting money from the diseased," and of "having so small cunning, that by reason thereof, they did sometimes impair and hurt their patients rather than do them good." Wherefore, it was enacted, that practically anyone might practise surgery who thought he had a gift in that direction.

For a long time after this, the physicians had the pleasure of tyrannising over both the surgeons and the apothecaries. The apothecaries had the advantage of the assistance of the powerful Company of Grocers, of which they formed a part, until the reign of James I. Then for the first time they were incorporated, but it was not till a few years later, in 1616, that they were definitely separated from the grocers and established as an independent company, under the name of the Society of Apothecaries of London. They were not, however, free from the College of Physicians. Either the President, or some physician delegated by him took part in the examination which had to be passed before an apprentice could be made free of the company, and the duty of inspecting and destroying adulterated drugs, which was transferred to them from the grocers, was carried out in conjunction with, and at the command of, the physicians. The apothecaries were the pharmaceutical chemists of that time, and, like the chemists of the present day, seem to have taken every opportunity of prescribing as well as of dispensing medicines. At first the College of Physicians resented this, and summoned many apothecaries before them, and fined some and "excommunicated," or, as we should say in the present day, "boycotted" others. Still the practice grew, and at last the apothecaries claimed the right of prescribing as well as dispensing. The struggle between them and the physicians was long and bitter, and it was not finally settled till a judgment was given in their favour in the House of Lords in 1708. During this time the surgeons and barbers remained united, and it was not till 1745 that they finally parted company, the surgeons establishing themselves independently in Surgeons' Hall, as the Corporation of Surgeons of London.

In 1748 the apothecaries obtained an Act of Parliament which confirmed their power of prescribing medicines, gave them additional powers of examining, and made it illegal for any man to dispense medicine within seven miles of London without their licence. It now became common for medical men to hold both the licences of the apothecaries and surgeons, and thus arose the so-called surgeon-apothecary, and in his hands was the greater part of the practice of the country. After they were beaten by the apothecaries the power of the physicians rapidly declined, and they seem to have retired into a state of sulky and offended dignity, and not to have taken the part they might have done in controlling the education of the lower grades of the profession. At the end of the last century the Surgeons' Corporation seems to have died a natural death, and now was lost the great opportunity of uniting the physicians and surgeons, which will probably never return. The College of Physicians has always maintained that surgery is only a branch of medicine, and that their licence entitles its holder to practise both; and it is much to be regretted that they did not act upon this assumption. At the time when surgery was practised chiefly by illiterate men, who also undertook the trade of "barbery," any union between the ignorant barber-

surgeon and the cultivated physician was out of the question. But in 1800 things had changed, and the physicians need not have felt it beneath their dignity to welcome within their body a class of men amongst whom had but recently been Percival Pott, Cheselden, Sharp, and John Hunter. Yet although many surgeons also recognised the inseparability of medicine and surgery, the idea of uniting the physicians and surgeons seems never to have been entertained, and the College of Surgeons in its present form was founded. Possibly if this desirable union had taken place, the encroachments of the Society of Apothecaries might have been withstood. As it was the surgeons became rather the allies of the apothecaries, and upon the surgeon-apothecaries fell the task of raising the lower grades of the profession to a higher and more dignified position. Under their influence was passed the Act of 1815, which gave the apothecaries further powers of examining, and extended their jurisdiction to the whole of England and Wales. This Act was evidently intended to perpetuate a lower grade of the profession, who should combine the trade of the druggist with the practice of medicine. That this was so is shown by the fact that the apothecary was bound under heavy penalties to prepare prescriptions ordered by a physician. It was also intended that the chemist and druggist, who was now arising as an independent tradesman, should not be allowed to prescribe. The apothecaries were not, however, content with this inferior position, their ambition being to grant a licence on equal terms with the College of Physicians. They consequently limited their apprenticeship to five years, and made attendance at a medical school compulsory; and it cannot be denied that at this time they did more to raise the general standard of knowledge in the medical profession than any other body. While doing this, however, they neglected their proper business, and allowed their influence in the drug trade to slip from their hands till, in 1841, a separate society — the Pharmaceutical Society of Great Britain — was established, which relieved them from their last duties in connexion with that trade. Finally, the Act of 1858 practically made the licences of the two Colleges and the Apothecaries' Society equal. At the same time some of the evils that it was intended in 1815 to correct have reappeared in an aggravated form. By the destruction of the old apothecaries, who sold their drugs and gave their advice for nothing, the field has been left open to the chemists and druggists, who now probably do about as much practice as the legitimately qualified medical men. The apothecaries are thus as it were "hoist with their own petar." They have raised the general practitioner till the College of Physicians has at last condescended to take notice of him, and arrange a suitable examination for his benefit. They have lost every trace of influence in the drug trade, and their licence confers no special privilege on its holder; and it need not be said that few would not prefer the letters L.R.C.P. after their names to L.S.A. Consequently, all reason for their continued existence has disappeared. It is useless to plead as an extenuating circumstance, that they did good work in raising the general practitioner sixty years ago. They have forgotten that it is said "Be not weary in well-doing," for they seem soon to have wearied, and practically for the last quarter of a century they have done less to improve medical education than any other body in this division of the kingdom, the University of Oxford perhaps excepted. But it is not likely that they will retire from the false position into which they have thrust themselves; it could hardly be expected from human nature. To call in the aid of the State would be a great calamity for the medical profession, which has so far managed its own affairs. There is, however, another alternative and that is, the union of the two colleges for the purpose of examination. The College of Surgeons now holds a position of nearly equal, if not equal dignity, with the College of Physicians. To this it has arrived by the improvement of the science and art of surgery, which it represents. It has, perhaps, done its duty better than either of the other corporations. It has never allowed the control over surgical education, from the highest to the lowest grade, to slip from its grasp, nor has it until quite recently undertaken any duties properly belonging to another body. The union for the purpose of examination of such a body with the physicians ought to present no difficulties, and if it were effected the Apothecaries' Society would probably before long die a natural death. No further conjoint scheme would be wanted for England. At present something is urgently required; not so much to protect the public from ignorant practitioners, for that I

believe is sufficiently done by all the examining boards, but for the protection of the student from the present irregular, unscientific course of education which he is so often allowed to follow.

## Introductory Address

DELIVERED AT

### ST. THOMAS'S HOSPITAL,

*On the Opening of the Winter Session, October 2nd, 1882.*

By SEYMOUR J. SHARKEY, M.A., M.B. OXON.,

ASSISTANT-PHYSICIAN, JOINT LECTURER ON PATHOLOGY, AND DEMONSTRATOR OF MORBID ANATOMY AT THE HOSPITAL.

(Concluded from page 564.)

Of course it remains a question of degree whether improvements in the treatment of diseases have kept pace with the increase in our knowledge of them. But that great improvements have been made admits of no doubt. One of the most important outcomes, however, of our advances in physiology and pathology and the natural history of disease is that we have recognised the following facts: that many affections are incurable, that they depend upon certain definite causes, and that these causes are often avoidable. Hence the importance of what is now termed "preventive medicine." In our treatment of chronic diseases we place our patients, as far as we can, in conditions which arrest the progress of the morbid changes which are going on in their organs. But why not prevent these changes altogether? This must evidently be our aim both now and in the future; though it is very questionable whether people will ever have the wisdom to submit to restrictions and rules of life in order to avoid miseries which they have never tasted.

There remains yet another department of therapeutics, to which the profession may point with feelings of legitimate satisfaction, and that is the application of surgical methods to cases upon which the administration of drugs or any other treatment whatsoever can necessarily have but little effect. The diseases referred to are abscesses in some of the large parenchymatous organs, collections of pus in serous cavities, the various forms of acute and chronic intestinal obstructions, the partial or complete removal of diseased organs, &c. The possibility of treating such affections depends of course upon our ability to diagnose, or at least suspect, their presence. And it is the increasing power which the progress of our science in various directions has given us of localising disease which has made these surgical procedures in any degree feasible. But the most important factor of all in these modern improvements has been the introduction of antiseptic surgery. Whatever may be the true *rationale* of Lister's method, whether the details he recommends need to be carried out in their entirety or not, or whatever may be the opinion of individuals regarding it, every unbiased man must confess that it has produced a revolution in that department of surgery which was formerly the field of the most unsatisfactory and fatal operations. The comparative impunity with which antiseptic surgery allows us to manipulate the peritoneum and other delicate and sensitive structures has not only resulted in the successful treatment of many patients, who would formerly have perished under the same ordeals, but it has likewise emboldened the surgeon to attempt operations which he would not have dared to do before, and even to make explorations in cases where life is threatened by obscure conditions.

To sum up, then, what can be said for the principles of modern treatment? We have thrown down the idol of universal specifics, which men had hewn out of false conceptions of disease. We have set up in its place rational scientific treatment, founded upon the knowledge of physiological processes in health and in disease; and we aim, as far as drugs are concerned, at the discovery by observation and experiment of the physiological action of substances which can then be used with greater precision in therapeutics. And although this rational pharmacology is still in its infancy, we already possess some drugs the action of

which we fairly well understand. We have a few remedies which appear to have just claims to the title of specifics, and we still harbour a probably legitimate hope of discovering others, which may be effectual in certain diseases before they have produced serious organic lesions. Great strides have been made in medical surgery, and we seem likely to advance still further in this direction. But our grandest aspirations lie in the path of preventive medicine, a department which should not only embrace attempts to exterminate some diseases, and to diminish the number of persons who fall victims to others; but must likewise include efforts to prevent the extension of morbid processes which have already begun in the organs of our patients, by regulating their lives in accordance with the teachings of physiology.

It will now be evident to you, gentlemen, that if the general view I have put before you of the principles of modern medicine be correct, there is an interdependence between all the subjects which are embraced in the medical curriculum, such as did not exist in former times. Clinical medicine has to be studied in the light of pathology, pathology in the light of normal anatomy and physiology, and the latter in the light of chemistry and physics. Nor must it be forgotten that what has really given medicine a claim to be placed among the sciences is the recognition of physiology as its basis, and what has given physiology itself precision is the experimental method of investigation. We do not for a moment assert that without vivisection there would be no physiology: but the irreconcilable opponents of the former cannot even be convinced of the great advantages which have resulted to physiology and to medicine alike from the practice of experimenting upon living animals. The fault, however, lies with the anti-vivisectionists, and not with us. For the foundation of medicine is physiology, and one of the essential factors in accurate scientific physiology is experiment. To appreciate these propositions one must first realise the facts and history of physiology and of medicine. But this cannot be done, though some insist that it can, by people who have little or no knowledge of these sciences. The answer to those who would suppress vivisection altogether lies not in quoting individual useful applications to medicine of facts which have been discovered entirely by vivisection, but in pointing to the comparative precision which pervades the whole of modern physiology, and which is gradually being introduced into practical medicine, a precision which we owe to experimental methods of research.

True scientific principles are as old as Hippocrates, but the field of observation has been widely extended. With all our increase in scientific knowledge, however, it is no easier, probably harder than ever, to become a good practitioner. A man might know everything and yet be a very bad doctor. Now, as of old, no amount of book-learning will make up for deficient dexterity in the examination of patients, or for the want of clinical experience. All methods of investigation must be carefully learnt and skilfully applied. Stores of knowledge must be at command, and the reasoning powers must be called into play to a degree probably not surpassed in any other profession. The best means of ascertaining what is really the scientific method of medical practice is to watch the work of a good physician by the bedside. A few years ago this school had to mourn the loss of one of its brightest luminaries, Charles Murchison, an eminent scientific physician and consummate teacher. His wide and varied knowledge of anatomy, physiology, and pathology, which he applied with such ability by the bedside, his splendid powers of observation, his keen logical acumen, his clear and easy exposition, and his contagious enthusiasm, formed a whole the charm of which has rarely been equalled, and can never be forgotten by his pupils. Nor can we mention Dr. Murchison without being reminded of another loss which we have this year sustained in Dr. Peacock, long a member of our staff, whose methodical and accurate observations have placed him among the highest authorities in more than one obscure region of pathology, and whose lively interest in medicine was shown by the eagerness with which he clung to the duties of his profession up to the last moments of his life.

But it may be asked, Have the modern methods been productive of good unalloyed? Are there no evil tendencies to be striven against? The increasing power of localising disease, with which we have just reason to be satisfied, frequently leads practitioners to look upon the body as a number of separate organs, each of which has its own peculiar affections and its own proper methods of treatment

The grand object often seems to be to diagnose the disease, and then to prescribe drugs said to be beneficial in it. But if physiology has taught us one thing more certainly than another, it is the intimate union of the individual parts of the body to form a concrete whole. One organ cannot be deranged without altering the conditions which surround the others, and interfering with the healthy composition of the blood and with the normal course of nutrition. Moreover, some organs are united by even closer bonds, in the form of nerve communications; or they have some similarity of function, which enables them to a certain extent to act vicariously for each other. Consider the innumerable derangements of health referable to almost every part of the body, which may result from the physiological cessation of the functions of the uterus and ovaries at the climacteric. In this instance energetic factors in the production of the vital equilibrium suddenly cease to exert their influence. The patient has lived long enough to have alterations of an abnormal kind produced in some of her tissues. These, if they are not fanned into a blaze by changes which then take place in their nutrition, are at least productive of functional disturbances within the area which they occupy. This is a typical instance of a condition which affects not one organ only, but the whole vital equilibrium, and the re-formation of the latter on an altered basis sometimes takes years to effect, sometimes is the source of never-ending ill-health. In any case a rational and effectual treatment must rest, not on a consideration of the state of one organ alone, but of all the physiological processes which take place within the body. Nor is this an isolated example. A very large proportion of local diseases produce widespread effects on the organism in general, and cannot be rationally treated by confining our attention to the part which is most conspicuously at fault.

Another offspring of modern medical thought is the tendency to scepticism—a tendency which we must not sweepingly condemn. It has arisen mainly with regard to the treatment of disease by drugs, and is the natural result of increasing knowledge. When a medical man studies disease from our present point of view, and is brought face to face with the wreck which it makes of the most vital structures, he must indeed be illogical if he does not rapidly cease to believe in the efficacy of any drugs whatsoever, either to repair the damage done, or to act as a substitute for the diseased organ in the economy. This scepticism regarding the possibility of finding specific cures for diseases in general is a most laudable trait, and shows an appreciation of the principles of modern therapeutics which is likely to lead to a far more effectual treatment of the patient than any blindly empirical administration of remedies.

But, gentlemen, you must not misunderstand me, and suppose that I have less confidence than I really have in our Pharmacopœia. I believe it to be composed of—first, a small number of very useful drugs, the physiological action of which is known, and the application of which to diseased conditions is of incalculable value; secondly, it contains a considerable number of remedies, the efficacy of which has been proved in many abnormal conditions, though the *rationale* of their action is still unknown; and, lastly, it contains a host of articles which some people assert to be useful for one thing, some for another, but about which very little of any value is known. Now the sceptic, who seems to me to be culpable and unscientific, is not he who has no belief in, and consequently discards, the motley collection of substances contained in the third category, but he who declines to use any drugs except those of the first, the physiological action of which is well understood, and for the administration of which he can see a *rationale*. Such a one will not use those medicines, the properties of which have been ascertained by a long series of observations, while their mode of action is obscure. This is an illegitimate and reprehensible scepticism. For although it must be the aim and glory of medical science to add constantly to those drugs the physiological action of which is known and the application of which to disease is so much the more certain; still the medical art must always remain one of observation and experience, and it is rational and scientific to act upon the results of these, though we may have long to wait for an explanation of what occurs.

It has often been remarked that the best physicians use few drugs, and, compared with the whole contents of the Pharmacopœia, the rational scientific sceptic will have only a small number of remedies which he cares to prescribe; but making himself by constant observation more familiar with

their action, and with the conditions to which they are applicable, he will use them rather as arms of precision, and his treatment will be to the point and effectual; while what may be called the "mitrailleuse" system of the less sceptical practitioners of former days relied rather upon the number of substances which were mixed together in the hope that some might hit the mark.

In the short account which I have presented to you of what appear to me to be some of the leading principles of thought in the medicine of to-day, I have implied that we are entitled to feel a certain degree of satisfaction in the progress which has been made. But let us remember that what we now know, and what we can accomplish by our art, is but a very small fraction of that which will one day be achieved by our successors. Let us make a modest estimate of the present state of science, and not give anyone in future times the opportunity of quoting boastful utterances of ours, as I am now about to quote a surgeon who flourished some three centuries ago. Ambrose Paré wrote thus—"God is my witness and all good men know that I have now laboured fifty years with all care and pains in the illustration and amplification of my art, and that I have so certainly touched the mark whereat I aimed, that antiquity may seem to have nothing wherein it may exceed us beside the glory of invention, nor posterity anything left but a certain small hope to add some things, as it is easy to add to former inventions." Let that be a warning to anyone of us who is inclined to exult in the present state of science, which may have made more progress at the end of the next three centuries than it has since the time of Ambrose Paré.

In days gone by many a sect, many a system of medicine has flourished and decayed, and whatever truth existed among their errors has been built into the scientific fabric of to-day. Homœopathy alone remains. But even homœopathy has discarded many of the absurdities of its founder, Hahnemann. It professes to accept and be guided by the data of modern science, and to differ from us only in the treatment of disease. It seems to me, too, that many professed homœopaths have practically retired even from this position, and have faith no longer in "dynamisation" and infinitesimal doses, but hold merely to the theory "*Similia similibus curantur*." This dictum is a distortion of a truth, and should express nothing more than this—that if we give drugs in large poisonous doses, we ascertain by the symptoms produced the organs on which they act, and we then administer them in smaller quantities when we wish to elicit their physiological action in cases of disease. The truth which is really involved in "*similia similibus curantur*" is nothing more than the elective affinity of certain drugs for certain organs, and the fact that if given in poisonous doses they derange the action of these organs. But this is not a method of experimental pharmacology which is characteristic of homœopathy, but one which has long been used in ordinary common sense medicine. Those homœopaths who differ from us in little more than this theoretical question, as to why certain drugs are indicated in certain diseases, have no right to place themselves under the banner of another sect, thereby deceiving the public, who are led to believe that their imposing name implies a *bonâ-fide* difference in practice. But the rest of the homœopaths, if there really be a remnant, who can plead that they honestly believe in infinitesimal doses, in the dynamisation of drugs by trituration and dilution, and in other palpable absurdities, may practise upon a deluded section of the public, but cannot possibly be received as the colleagues of reasonable men. No, gentlemen, the day has long gone by when systems of medicine were admissible. There is but one system—the scientific,—which rests upon observation and experiment, and upon the application of science in general as a guide to the knowledge and treatment of disease. Therefore avoid being led astray by the seductive theories of any sect whatever. Be neither homœopaths, nor allopaths, nor antipaths, nor any other "paths," but scientific medical men. And if you really are such, you will secure one of the greatest sources of happiness through life, one of the greatest consolations in its many uncertainties—an enthusiasm for your profession. And having that, you cannot fail to feel also a love and enthusiasm for the school where you first became imbued with the principles of scientific medicine.

THE salary of Mr. Butler, surgeon at the Brighton Sanatorium, has been increased from £100 to £150 per annum.

# ON THE RELATION OF PARTIAL RETENTION OF URINE TO ITS DECOMPOSITION WITHIN THE BLADDER.

By WILLIAM S. SAVORY, F.R.S.,  
SURGEON TO ST. BARTHOLOMEW'S HOSPITAL.

THE opinion is, I believe, current, it is certainly general in our books and elsewhere, that inability to empty the bladder completely is a common cause of chronic inflammation of the viscus, because a portion of stagnant urine is retained until it is decomposed, and so becomes an irritant. In this way, by confining some of the urine until it becomes decomposed, it is stated that all forms of obstruction to its exit produce chronic cystitis. Now, is not this opinion that residual urine thus remains to decompose based on a misconception of the actual facts, or at all events of the cause, in such a case? Is it not assumed that the urine which remains behind is a fixed quantity, and therefore stagnant? Is it not overlooked that, although the bladder may be never emptied, yet that, inasmuch as a large portion of the urine it contains is frequently leaving it to be replaced by another portion which is continually entering it, the same portion of urine does not necessarily remain long enough in the bladder to become, of itself, the source of the mischief that ensues? Of course urine may remain long enough in the bladder to decompose, for no one needs to be reminded of the fetid urine reeking of ammonia in chronic cystitis; and it admits of demonstration that urine which enters the bladder in a healthy state is very rapidly changed by the disordered secretion of that organ. But this need not depend simply on retention, either total or partial. Micturition may be frequent, and the bladder may be frequently quite emptied, and yet the urine that flows may be putrid; or urine may be retained for a very long period, and yet when it escapes there may be no evidence of decomposition. In many cases, for example, where a person is confined to the recumbent position, the bladder is never able to expel the whole of its contents, and yet this state of things may continue for weeks without the residual urine showing any sign of decomposition; and in other cases, where it may even become necessary to draw off the urine in this enforced position of the patient, the bladder, in all probability, never becomes completely emptied, and yet, at least for a long while, the urine passes without change. Therefore, even if all reasoning on the matter be excluded, it cannot, in the face of these facts, be accepted that as a rule residual urine is to be regarded as the source of the mischief that is so often associated with it. No doubt the longer any given quantity of urine is retained in the bladder, when the causes of its decomposition are ripe there, the farther will its decomposition proceed. But the duration of the retention of any given portion is by no means represented by the amount of residual urine after each act of micturition. The quantity of urine which enters and escapes from the bladder daily must rather be considered. Just as the water drawn off from a cistern gives no evidence of being stale or changed, although the reservoir is never emptied, because the whole of its contents are nevertheless rapidly renewed.

If healthy urine is passed into a bottle capable of holding, say, two pints, and the bottle as it becomes filled is from time to time only partially emptied, so that always about half a pint be left behind, the urine in the bottle, even after months, will still retain an acid reaction. It does not become ammoniacal or acquire the characters of the urine in chronic inflammation of the bladder. And in this experiment the circumstances, so far as ordinary decomposition of stale urine is concerned, are, on the whole, far more favourable to change; for although the temperature of the bottle may not be so high as that of the bladder, yet air is frequently and freely admitted, and of course it is always abundantly present. If the changes by which urine becomes ammoniacal are due only to long-continued partial retention, how is the negative result of this experiment to be explained?

Yet, although I venture to think that the prevailing opinion in this respect is not well founded, I am indeed very far from saying, or even intending to suggest, that

there is no evil in partial retention. On the contrary, it is clear enough that the presence of residual urine implies some delay in the escape of a portion of it, and therefore in a corresponding degree favours the advance of decomposition. But this, I need not remark, is a very different view from that which regards partial retention as a common starting-point of cystitis and the further evils which hence ensue. But then the fact remains that these two evils—residual urine, the result of partial retention, and chronic cystitis—are very commonly associated. Can this be explained? The direct and immediate cause of the decomposition of urine in the bladder, which enters it in a healthy state, is the presence and action of a morbid secretion of the mucous membrane. Practically the changes of urine in the bladder are dependent on the action of unhealthy mucus, and the degree of decomposition, although of course affected by the time the urine remains there, is yet chiefly determined by the character of the diseased secretion which mingles with it. Even under the conditions of health it is the mucus present in the urine which mainly determines the decomposition of urea, as the result of the simple experiment of filtering fresh urine shows, and when mucus is morbid it is far more destructive. Now, this disordered secretion must be the product of an unhealthy membrane; and while there is but little difficulty in understanding how, when the texture of its lining membrane is altered, the bladder is hampered in its action, and its full and complete contraction impeded, there is hardly less difficulty in believing that a full and complete contraction of it from time to time is an essential condition of a healthy mucous membrane, and of a due secretion and free escape of healthy mucus. Therefore, the conditions under which the bladder is only partially emptied are oftentimes the very conditions under which unhealthy, and therefore highly mischievous, mucus is brought in contact with the urine there.

## ON A NEW TEST FOR ALBUMEN IN URINE.

By WM. ROBERTS, M.D., F.R.S.,  
PHYSICIAN TO THE MANCHESTER ROYAL INFIRMARY.

WHEN an albuminous urine is treated with a saturated solution of common salt, not the slightest reaction takes place; but if the brine be slightly acidulated with hydrochloric acid, the albumen is thrown down as a dense white cloud. This reaction constitutes a most delicate test for albumen in the urine. The best degree of acidulation for this purpose is obtained with about 5 per cent. of the dilute hydrochloric acid of the Pharmacopœia. A little more or a little less acid makes no appreciable difference in the sensitiveness of the test. Common salt dissolves in about two and a half times its weight of water at 60° F., and increase of temperature does not sensibly increase its solubility. The salt of commerce is always more or less dirty, and the solution requires filtration to fit it for use as a test. The salt solution should be fully saturated, otherwise the observer is apt to be led into error. In preparing the test with our common English measures the readiest plan is to mix a fluid ounce of dilute hydrochloric acid with a pint of water, and to saturate this with common salt, and filter. Dilute hydrochloric acid may be replaced by dilute sulphuric, dilute nitric, or dilute phosphoric acid. All these acids are of the same saturating strength in the British Pharmacopœia, and all of them yield with saturated salt solution an equally sensitive reagent for albumen. Even acetic acid may be used, but the delicacy of the test in that case is not quite so great as when it is prepared with one of the mineral acids. The method of applying the brine test is similar to that followed with nitric acid. A portion of the suspected urine is placed in a test-tube, the test-tube is then held very much aslant, and the salt solution is allowed to trickle along the sides of the tube to the bottom, so that it may form a distinct layer below the urine. If albumen be present, a white cloudy zone appears at the junction of the two fluids. Or the proceeding may be reversed. The salt solution may be first introduced into the test-tube, and then the urine added with the same precautions as before, so as to obtain two distinct layers, one above the other, in the test-tube. It is important to be aware that the precipitation of albumen by acidulated brine is not due to a true coagulation. In this respect the

brine test differs from nitric acid and boiling. In the two latter cases the albumen is transformed into the insoluble modification, which is known as "coagulated albumen." But when albumen is thrown down from urine by acidulated brine, the precipitate is not insoluble; on the contrary, it is redissolved by free addition of water, or even by free addition of the albuminous urine itself. It is therefore essential to the efficient application of the test that the salt solution should be in excess at the point of expected reaction. This end is obviously secured in the above-described methods of testing. It may also be secured by adding to the suspected urine a volume of the salt solution at least equal to that of the urine in the test-tube. If this point be not attended to the test is unreliable. For instance, if acidulated brine be added drop by drop to an albuminous urine, and the mixture shaken up after each addition, the first few drops either occasion no turbidity whatsoever or the turbidity produced disappears on shaking. But when by successive additions the quantity of brine approaches to or surpasses the volume of urine operated on the turbidity remains permanent. In point of delicacy the salt test stands on a par with nitric acid. The minutest trace of albumen detectable in the urine by nitric acid is also detectable with equal ease by acidulated brine. In high-coloured urines the brine test is distinctly superior. In this class of urines nitric acid produces a deepening of the tint, with, often, a disengagement of gas, which interferes with the sensitiveness of the reaction, but the brine test neither alters the tint nor causes disengagement of gas. On the other hand, I think that nitric acid gives a better idea of the quantity of albumen present by the density of the white cloud produced than does the brine test. In addition to albumen, acidulated brine precipitates peptones, which are sometimes present in urine; so that occasionally a slight cloudiness is produced by the salt solution where nitric acid and boiling (which do not precipitate peptones) produce no reaction. This distinction in the action of the brine test may hereafter lead to interesting information. In dense urines, highly charged with urates (but not containing albumen), the addition of nitric acid sometimes throws down the amorphous urates in the form of thick white clouds, and it is necessary to apply heat to distinguish with certainty the cloudiness so produced from cloudiness due to albumen. The salt test does not throw down the urates in this way. It is well known that the urines of patients who are taking large doses of resinous substances (such as the resin of copaiba), although free from albumen, yield a cloudiness with nitric acid in the cold, but if the urine be previously made hot, nitric acid produces no such reaction. This difference serves to distinguish cloudiness due to resin from cloudiness due to albumen. The brine test also produces a cloudiness in resinous urines, and the reaction occurs whether the urine be hot or cold. To avoid the fallacy thereby arising, all that is necessary is to add an excess of the urine which is being tested. If the cloudiness be due to albumen it disappears on such addition, but if it be due to resin, the cloudiness does not disappear on the addition of more urine. One of the chief advantages of the salt test is its incorrosive character. It does not stain nor burn holes in garments and carpets, nor fleck the hands with yellow spots. The use of it makes it possible to arrange a pocket-case for urine testing that shall not be a terror to the wearer. From this point of view the substitution of the salt solution for nitric acid will be a real boon to practitioners.<sup>1</sup> The salt test has this additional convenience—that it enables us to test successively for albumen and sugar on one and the same sample of urine. The suspected urine is first tested for albumen with the salt solution, and then Fehling's solution, or, still better, a pellet of the solid Fehling's test sent out by Cooper is added, and heat applied. After boiling a few seconds the absence or presence of sugar is ascertained. The admixture of the brine in no way interferes with the copper reaction, in case sugar should exist in the urine.

Manchester.

<sup>1</sup> I have carried about with me for some months past a little pocket-case (which is only a stiff-backed cigar-case) which I have found a useful and safe clinical companion. It contains a book of litmus papers; a narrow corked phial filled with acidulated brine; a test-tube charged with Cooper's pellets of the solid Fehling's test, guarded with an India-rubber stopper; and, lastly, an empty test-tube, also provided with a cork. This compact arrangement furnishes the means of ascertaining the reaction of the urine, and of testing it in the most delicate manner for albumen and sugar. The empty test-tube also serves to carry home a specimen of the urine for further and more minute examination. The "pellets" (made after a suggestion of Dr. Pavy) are sent out by W. T. Cooper, chemist, 26, Oxford-street, London.

## THE VOLUMETRIC ESTIMATE OF ALBUMEN IN URINE.

By GUY NEVILLE STEPHEN, M.R.C.S.

IN the wards, and in private practice, the method most commonly employed for detecting the presence and estimating the amount of albumen in urine is the application of heat, the result being aided and verified by the addition of a few drops of nitric acid. As a simple test, this method, though not absolutely free from objection, either on the score of chemical accuracy or ease of application—a matter of considerable importance in private practice,—is yet, when applied with ordinary care, sufficiently reliable and searching to warrant its popularity, and prevent one receiving as anything more than scientifically interesting the various other albumen tests that have been and are from time to time proposed. As a volumetric test, however, applied by precipitating the albumen, allowing it to cool and subside, and then noting the proportion of the albumen which has collected to the rest of the fluid in the test-tube, and reading it off as a fraction, it is at best but a very rough method, with numerous sources of error, and, as commonly employed, gives most inaccurate and deceptive results, due partly to inherent causes, and partly to want of care in throwing down the whole of the albumen and allowing it to thoroughly cool and subside. Such as it is, nevertheless, this method is even more universally employed in the estimate of albumen than are the same reagents, heat and nitric acid, as a simple test of its presence; but probably less, because general approval is accorded to it, than because of the other methods generally known none has a claim to be substituted for it—Esbach's test being, if more accurate, much more tedious, while the actual weighing of the albumen is, from the readiness with which albumen absorbs moisture, a process that taxes the resources of even a skilled chemist. Since, therefore, we are at present in possession of no easy, rapid, and trustworthy method of estimating albumen, every fresh idea and suggestion on the subject should receive a thorough clinical trial before being relegated to the chemical laboratory; and this has not yet been accorded either in England or abroad to a method suggested by Turret of Troyes as far back as 1872. The basis of this method is the precipitation of albumen by the double iodide of mercury and potassium, and it is equally applicable both for testing for and estimating albumen. The manner of procedure is extremely simple, and in practice the testing and estimation may be done at the same time, but for the sake of descriptive clearness the testing will here be taken first.

*Testing.*—For this all that is required is a solution of the double iodide of mercury and potassium and some acetic acid. The urine to be tested first must be rendered distinctly acid by the help of some of the acetic acid, and then a few drops of the solution added to it. If albumen be present a white opaque flocculent precipitate immediately forms, which on the one hand requires no verification like that formed by the application of heat to only slightly albuminous urine, and on the other is not, like the precipitate of nitric acid, liable to be redissolved by adding too much of the reagent. In point of delicacy, moreover, the test is superior to either of these, as the precipitate will form in the presence of as small a quantity of albumen as five centigrammes to a litre of water, a result which is only equalled by the very uncertain phenic acid test, and by heating with sulphate of soda. To the practitioner, too, who wishes to test urine for albumen by the bedside of his patient, it is a very distinct advantage to be able to dispense with test-tube, spirit lamp, and strong nitric acid, and to carry with him nothing but two small phials, and perhaps some litmus papers. It is scarcely necessary to enter into possible causes of confusion, as the only case in which the reagent under discussion itself gives rise to any other than albuminous precipitate is in the urine of patients who are taking alkaloids, when a precipitate may be formed which, however, is soluble either by heat or by the addition of alcohol; while the errors that may be entailed by the employment of the acetic acid, together with the means of avoiding them, are already for the most part well known. In urine loaded with urates a precipitate of uric acid may

be thrown down when the acetic is added, but merely diluting the urine with water will cause it to disappear. Mucus, too, if present, may also be precipitated by the acid, but will give no trouble, as it is quite different in appearance to the precipitate of albumen, and will have dropped to the bottom before the solution is added; and, lastly, if the acetic acid be not used in sufficient quantity to make the urine decidedly acid, urea may be thrown down by the after addition of the potassio-mercuric iodide.

*Estimation.*—The process for this is extremely simple and rapid, and only differs from that described above in that the solution employed is of known strength, and that the quantity used both of it and of the acid and urine must be carefully noted, and the complete precipitation of the albumen proved by a second solution. Besides the solution and acid, a glass, graduated in cubic centimetres, a pipette giving drops of five centigrammes, and a few glass stirrers, are all that is required. For the precipitating solution the formula is—potassii iodidi, 3 grms. 22; hydrargyri bichloridi, 1 gm. 35; aquæ destillatæ, q.s. ad 100 cc. For the confirmatory solution—hydrargyri bichloridi, 1 gm.; aquæ destillatæ, q.s. ad 100 cc. One drop of the precipitating solution given by a pipette of the above size precipitates 0.005 of albumen; so that so many drops as it takes to precipitate all the albumen, so many times 0.005 of albumen must there have been in solution. To save trouble in calculation, the same quantity of urine should always be taken, and the best quantity to take is 10 cc., as then the number of drops of the solution that it takes to precipitate all the albumen in this quantity of urine represents so many half grammes of albumen to the litre. Take then 10 cc. of urine, and add two of acetic acid, and stir with a glass rod; then add the precipitating solution drop by drop, stirring carefully each time, until the precipitate is no longer resolved in the albumen in excess—i.e., as yet unaffected by the reagent; then after each drop of the solution put a drop of the urine on a porcelain dish and watch if a yellowish-red colour appears on adding a minute drop of the confirmatory solution. As soon as it does, all the albumen is precipitated and the process is finished, and the amount of albumen per litre will be at once arrived at by taking the number of drops employed of the precipitating solution, subtracting three as having been used in excess to make the yellow colour perfectly clear, and then considering the rest as so many half grammes.

The chemical reactions and data upon the above depends are  $2\text{KI} + \text{HgCl} = \text{HgKI} + \text{KCl}$ . When the double iodide of mercury and potassium thus formed is added to albuminous urine sufficiently acidified, all the albumen is precipitated in combination with the mercury and iodide of the reagent, in the proportion of the equivalent of  $\text{HgKI}$ , weighing 393 to 1 equivalent of albumen,  $\text{C}^{60}\text{H}^{70}\text{Az}^{11}\text{O}^{33}$ , weighing 1004, while the potassium is taken up by the acid of the urine. As long as any albumen remains in solution the double iodide of mercury and potassium will not form red iodide of mercury when bichloride of mercury is added to it, but it does so as soon as all the albumen is precipitated. The solution formulated above is such that every drop of 0 grm. 05 contains 0 grm. 00196 of  $\text{HgKI}$ , and therefore in accordance with the equivalents given will precipitate 0.005 of albumen.

The rapidity and simplicity with which the volumetric estimate of albumen may be performed by this method, as above described, are self-evident, and it has been thoroughly tested by the writer in the Hôtel Dieu of Marseilles, and its convenience and utility found to be very great, as it offers a ready means not only of watching, as is most important, the diurnal variations in the amount of albumen in a patient's urine, but of comparing, as is most interesting, the different quantities present in diverse cases and in various diseases.

St. Bartholomew's Hospital, London.

#### DEVONSHIRE HOSPITAL AND BUXTON BATH CHARITY.

By Dr. Robertson's report, presented at a meeting of the Committee of Management on the 7th inst., it would appear that the definite cost of the extension of the hospital has not yet been ascertained. Meanwhile the benefit resulting from the enlarged accommodation is already apparent in the increased number of patients and the proportional alleviation of suffering through the instrumentality of the institution. The returns of cards stating the ultimate result of the treatment received have been satisfactory both in quantity and kind.

#### NOTES ON THE ANTISEPTIC METHODS EMPLOYED IN THE SURGICAL PRACTICE OF THE BASE AND FIELD HOSPITALS: EGYPTIAN CAMPAIGN.

BY EDGAR M. CROOKSHANK, M.R.C.S.,  
HOUSE SURGEON OF KING'S COLLEGE HOSPITAL, AND ATTACHED FOR  
DUTY TO THE BASE AND FIELD HOSPITALS, ARMY MEDICAL  
DEPARTMENT.

VARIOUS antiseptic methods having been employed by the surgeons of the Army Medical Department in the treatment of the wounded during the Egyptian campaign, it may be of interest to many to read the mode of application and the results which I had the good fortune to observe.

*Treatment of First Wounded at Base Hospital, Ismailia.*—The wounded sent down from the front after the first engagements had been, and were, treated at the base hospital, Ismailia, mostly with dressing of carbolic oil, some with the carbolic or the chlorinated soda lotion. In these cases it was found that if not dressed for forty-eight, or even twenty-four hours, the wounds were septic and the dressings odorous, and unless the latter had been covered with gutta-percha tissue, in this climate not only the lotion, but the oil, evaporated, and with the dried coagulated blood and discharge became glued to the wound, so as, even after sponging or soaking in water, to be in most cases with difficulty removed, and the cause of discomfort and of pain to the patient.

*Treatment of Wounded at and after the Battle of Tel-el-Kebir.*—The wounded brought from the field to the advanced field hospital after the battle of Tel-el-Kebir were dressed with the iodoform and boracic acid dressing, in the following manner. The wound and skin around were purified by washing with a strong watery solution of carbolic acid (1 in 20), and the surface of the wound sprinkled lightly with the powder of iodoform; a piece of protective dipped in carbolic, in the absence of boracic lotion, was next applied to the wound, just sufficient to cover it, and over this a couple of layers of boracic lint, fixed by means of a gauze bandage, the latter, from its lightness, being preferable in this climate to the ordinary linen bandages. Of these cases, some in which the discharge was profuse, were dressed again the next day at Kassassin, and others were not seen again until they arrived at the base hospital at Ismailia. Of the latter, the following day those in which the discharge had not appeared on the surface of the dressing, and the patient expressed himself as comfortable, remained untouched; so that there were cases not redressed until two or even three days after the reception of the wound. In these cases, just as in those dressed the day after the engagement, the dressing was perfectly sweet and the wound healthy; and last, but not least, the dressing was removed with facility, and the patient prevented thereby from suffering either discomfort or pain—the latter, of course, being due to the action of the protective, which, while enabling the discharge to run from beneath it and permeate the boracic lint, at the same time prevents the latter from adhering to the wound. Some of these cases, more particularly the severe ones—e.g., shell wounds—remained in the hospital for some days before being transferred to ships for England, and during this time their progress was carefully watched, and in all cases the same condition remained of a healthy inodorous wound, and consequently the iodoform and boracic-acid dressing met with such approval on the part of the surgeons that all the wounded who have passed through the base hospital, and those already in it since the action at Tel-el-Kebir, have, with few exceptions, been dressed at one time or other in the manner described. Of the cases already in the hospital, two may be cited as examples—one, a sailor with compound fracture of the femur, the other a private with an extensive shell wound perforating and lacerating the calf of the leg. In both these cases the wound had been dressed with the chlorinated soda lotion; nevertheless the discharge was offensive, and the wound, especially in the second case, presented a sloughing and generally unhealthy appearance. The application of iodoform and the boracic dressing acted with marvellous

rapidity, the fetor being corrected, the sloughs separating, and the wounds presenting healthy granulating surfaces. In the case of the compound fracture, the wound, after a second application, was not dressed again for five days, when the patient was ordered on board the *Lusitania*, and, before leaving, the splints and dressing were readjusted. The wound in this case had remained perfectly sweet, and, doubtless, would have continued so if left untouched for a week, the time recommended by Professor Lister when a similar dressing has been applied after the performance of skin-grafting on a large sore.

*Antiseptics after Operations.*—After the extraction of a bullet, swabbing the cavity of the wound with a solution of chloride of zinc (forty grains to one ounce of water), rendering the wound antiseptic, and the introduction of a drainage-tube giving free exit to discharge, and encouraging the wound to fill up by granulation, gave excellent results; and a similar treatment was equally serviceable in gunshot wounds with sloughing tract and a tendency to the pocketing of discharge. After amputations, also, the forty-grain solution of chloride of zinc proved invaluable for swabbing the flaps, not only as a powerful antiseptic, but as a styptic also, stopping all oozing and hæmorrhage from small vessels. Arteries requiring ligation were secured by means of the sulphurous or green catgut introduced by Professor Lister, and used in this campaign for the first time in military surgery. This form possesses all the advantages of the carbolic gut over silk, and over the former of greater strength, decreased rate of absorption, and from a point of view of transport in the small amount of space occupied in packing, compared with the cumbersome bottles of the carbolised gut.

In the wards a lotion, consisting of one part of the forty-grain solution of chloride of zinc with three parts of 1 in 20 carbolic, proved of great value in encouraging the separation of sloughs and rendering the wound antiseptic. This was especially brought to notice in the case of a Life-guardsman whose arm had been amputated at the shoulder-joint for a severe gunshot wound. Extensive sloughing occurred within the flaps and pocketing of pus. The removal of a couple of stitches, the introduction of a large-sized drainage-tube and syringing out the wound thoroughly with the lotion mentioned brought away the sloughs, gave free exit to the retained pus, and produced such a marked change in the appearance of the wound and general condition of the patient, that from that time the balance was turned in favour of recovery. For correcting the fetor of wounds, iodoform shaken up with 1 in 20 carbolic and syringed into the interior of the wound, also proved useful in the wards. Finally, a case of amputation of the arm by the circular method, performed at the Base Hospital, Ismailia, with Listerian precautions, tended to prove that Listerism could be carried out with equally good results in military as in civil hospital practice. It may be added as a point of interest that in spite of the iodoform having been used in some cases over large wounds more freely than was recommended, with the exception of one or two cases of headache and general malaise which may have been due to other causes, there were at any rate no marked symptoms of iodoform poisoning, which has been commented upon so much of late and considered a drawback to its use. These slight symptoms, if due at all to the iodoform, only serve to emphasise the necessity of following Professor Lister's instructions of lightly dusting and not thickly covering a wound with the powder.

## CASE OF LYMPH SCROTUM, ASSOCIATED WITH FILARLÆ AND OTHER PARASITES.

By PATRICK MANSON, M.D.

TEHHAI, male, aged thirty-four, of Tchih Kang, Tehhiah-thop, a cotton carder; both parents are deceased, his father having died of a cough, his mother of old age; young brother well; has no sisters; as far as he knows there is no elephantiasis in his village. The scrotal disease for which the patient applied began when he was twenty-six with inflammation and abscess; inflammation and elephantoid fever frequently recurred. Six years ago a lymphous discharge from the scrotum began; the scrotum was then larger and more tense than at present. Ten months ago the patient had a long series of genuine ague attacks they

began as quotidian, after a time became tertian, and finally quartan. The illness lasted for seven months; he became very weak, coughed, and lost appetite; for the last month the scrotal discharge, which hitherto had intermitted, had become constant, and in consequence he was reduced to a condition of extreme debility.

Sept. 2nd, 1881.—Scrotum is larger than a man's head, and the penis is buried in it; femoral glands are most affected, especially those on the left side, which are large and varicose; only one or two are similarly affected on the right side. The greater part of the scrotal tumour looks and feels like an ordinary elephantiasis, but on the thigh aspects of the mass, especially on the left side, there are patches of large tense vesicles, and on the upper and anterior surface of the tumour, about two inches from the preputial orifice, there is a long dilated lymphatic quite an eighth of an inch in diameter. Lymph constantly escapes, spurting in a fine stream from a vesicle on the right side and from any vesicle that is handled at all roughly. Several pounds of lymph must have escaped to-day. The discharge is white, like watery milk, coagulates rapidly, and contains filaræ. Several were found during a brief examination of lymph drawn in the forenoon (at 11 o'clock). Blood drawn from the finger at 6.30 P.M. contained filaræ. He had no elephantiasis of the legs, nor did he give a history of chyluria.—3rd: As it was evident that the continued lymphorrhagia would kill the man in a very few days, I removed the tumour in the forenoon. It weighed over three pounds, and had the usual section of lympho-elephantoid scrotum. A scrotal hernia on the right side, firmly adherent to the bottom of the scrotum, gave much trouble in dissecting up the sac. Large lymphatics in the upper and outer corners of the wound discharged much lymph, and were therefore ligatured.—21st: The patient died this morning of dysentery and exhaustion. For some time before the operation he suffered from vomiting of food, and ever since the operation there has been difficulty of swallowing. The symptoms were those of stricture of the œsophagus. Watery arrowroot was about the only food he could swallow. Dysentery set in soon after the operation. At the time of his death the wound, though indolent, was clean and sweet, and was in no way responsible for the fatal termination.

*Post-mortem examination, on the same afternoon.*—Thin and wasted; feet cedematous. On opening the abdomen the bladder was found to be rather distended. The whole of the mucous membrane of the great intestine, from the ilio-cæcal valve to the anus, was covered with ulcers. A number of parasites, twelve in all, were found lying in the sub-peritoneal fascia, about the iliac fossæ and behind the kidneys. A similar parasite was found lying free in the right pleural cavity. Some of these parasites were coiled up in loose knots, and others lay extended. On being drawn from under the peritoneum they exhibited languid movements like those of tapeworm. The œsophagus, where the left bronchus passes in front of it, was ulcerated and thickened, the ulceration and thickening extending completely round the tube, and being about an inch and a quarter in breadth. The œsophagus and bronchus opened into each other by a small ragged hole in the ulceration, admitting a penholder, and in the left bronchus were two full-grown female lumbrici, that had evidently passed into this unusual situation immediately before or after death through this hole. The œsophagus was firmly attached to bronchus, and at the site of ulceration was so narrowed that the little finger could not traverse the stricture. The ulcer was very irregular, and in different places its surface was pitted with rough holes running into the walls of the tube under the mucous membrane. Lymphatics of groins over saphenous opening much enlarged, especially on the left side; they were firm but not hard, and gave the idea that the outer part of the gland had been distended, but had now collapsed and lay loosely on a very hard nucleus. Lumbar glands large, but nothing remarkable. Examined blood from lungs and spleen, and from both obtained a few filaræ. The juices expressed from the left groin gland contained filaræ in considerable abundance.—24th: The parasites referred to as having been found in the subperitoneal areolar tissue were long tape-like animals, twelve to fourteen inches long, one-eighth of an inch broad, and about one sixty-fourth of an inch in thickness. They were dead white, and moved distinctly when taken out of the body. The extremities were rather thicker than the rest of the body, and were rounded off. A hurried glance with the microscope showed one extremity to be lipped. I placed them in a mixture of

serum and urine, intending to examine them more carefully in the evening of the post-mortem, but was disturbed. Next morning I poured spirits of wine over them. To-day I find them so friable that I cannot make out the structures. There are no joints or articulations. The entire animal seems stuffed with clear globular egg-like bodies, in many of which double and treble outline, with appearance of nucleus, can be traced. These bodies are apparently held together by a loose fibrous matrix, which on pressure splits up longitudinally or ruptures transversely. The integument is very thin. One extremity appears to be provided with a narrow longitudinal slit, the other is distinctly lipped.

Amoy.

[We are informed that the tapeworm-like parasites were submitted to Dr. Cobbold for identification, and he finds that not only are they new to science, but they belong to the genus *Ligula*, hitherto not known to infest the human body. Accordingly he proposes to call the worm *Ligula Mansoni*.—ED. L.]

## REMARKS ON PROSTATORRHOEA.

By D. CAMPBELL BLACK, M.D., L.R.C.S. EDIN., &c.,  
EXTRA-PHYSICIAN TO THE ROYAL INFIRMARY, GLASGOW; PHYSICIAN  
TO THE GLASGOW PUBLIC DISPENSARY.

THE normal function of all glands is maintained by a healthy coördination of the three divisions of the nervous system—viz., the motor, the sensory, and the sympathetic. The integrity of such coördination may be disturbed by peripheral or central influences, or by lesions of the intercommunicating apparatus. Bodily waste and repair—the persistence of healthy structure,—equally with the normal secretion of all glands, are thus dependent on a healthy nervous system, and it in turn on a healthy blood-supply. If at any of the points indicated the normal influence of the nervous system be perverted, the due circulation of blood is interfered with, and in glands one or other of the following changes take place, as certain conditions predominate.

On the Basement Structure  
of Glands.

On the Secretion of Glands.

Neoplasm.	Degeneration.	Augmented or diminished secretion.	Changes in the composi- tion of the glandular secretion.
-----------	---------------	--	--

The functions of the sexual and urinary organs may be said to be compound in respect that they are partly voluntary and partly involuntary, and that some are participated in by purely cerebral influences, while others are exclusively reflex phenomena in association with given centres of the spinal cord, and thus totally independent of the higher nervous centres. To the former belong the functions of micturition, and to some extent the special sexual functions; while to the latter are to be assigned those of the testicle, the prostate, Cowper's and the other smaller subordinate glands. The nerve centre for the sexual organs is situated in the lumbar enlargement of the spinal cord, and presuming the integrity of the centre and reflex loop, the sexual secretory functions, while they may be influenced by psychical impressions, are carried on quite independently, as all vegetative functions are. In the light of the above propositions we have seen that these functions may be deranged by peripheral, central, or intermediate influences. Under the first category are recognisable the phenomena attendant on the presence of stone in the bladder, hæmorrhoids, preputial irritation, contracted meatus, prostatitis, and varicocele; under the second two categories the phenomena arising from disease or injury to the spinal cord, and the disturbed motor conditions thereby occasioned. These, it will be obvious, comprise retention and incontinence of urine, reflex pain, a peculiar form of spinal paralysis, excessive secretion of the testicle and consequent spermorrhægia, excessive secretion of the prostate (prostatorrhœa), &c.

When several glands discharge their peculiar secretion into a common emunctory it is often difficult to distinguish how far discharges from such emunctory are simple or compound, or to what extent they are the latter. This is notably the case with the urethra, as the term gonorrhœa sufficiently demonstrates. Empirics are never slow to find out the hidden or neglected arcana of medicine and surgery, and profit thereby at the expense of the credulity or un-

founded fears of their victims, backed up as they have been in the case of urethral discharges, other than gonorrhœa, by the sensational and ill-advised writings of such men as Lallemand and his followers. The frequency of urethral discharges, at stool especially, and at other times in rarer cases, did not fail to excite their notice, and they forthwith sought, and too often sought successfully, to associate such discharges with the "chamber of horrors" in which Lallemand and such as thought with him, delighted to revel, to the irreparable injury, bodily and mental, it may safely be asserted of countless thousands. As there is no system or form of quackery which does not depend for its maintenance on the kernel of truth within, the expediency of disentangling the true from the meretricious in the present instance is now sufficiently recognised, though there are still considerable differences of opinion among authorities on certain points, to one or two of which it is my present object to direct attention, record my experience, and invite discussion on the part of others whose opportunities of observation are of a more extensive nature than my own. The subject of involuntary emissions of semen is coexistent with the literature of medicine,<sup>1</sup> but comparatively little pathological significance was accorded to them until the ill-advised and hastily-generalised treatise of Lallemand appeared at Montpelier. Antecedent to this time happy ignorance prevailed upon the subject, and people consequently enjoyed physical and mental health. It was not until 1860, I believe, that a special discharge from the prostate gland was described by Professor Gross;<sup>2</sup> and in his admirable work on this and allied subjects Dr. Samuel W. Gross defines prostatorrhœa as an "excessive secretion of a clear viscous fluid, dependent upon chronic catarrhal inflammation of the tubular glands of the prostate. It is included by some authors in their description of chronic prostatitis; but it is an entirely independent disease, as it does not follow an attack of acute inflammation, nor is it attended with suppuration or other morbid changes of the parenchyma of the organ." Erichsen states that "the disease is characterised by the discharge of a few drops of ropy viscid mucus from the urethra after micturition and defecation. It is chiefly of importance from its liability to be confounded with spermatorrhœa, and from the depressing effect consequently produced on the patient's mind," and he further indicates that its diagnosis is to be effected by microscopic examination of the nature of the discharge, thereby indicating that if the discharge contain spermatozoa, the disease is spermatorrhœa; if they are absent, that it is prostatorrhœa. Professor Humphry, in treating of spermatorrhœa, remarks, "Accompanying this malady, or independent of it, there is sometimes a discharge from the urethra of a tenacious fluid, like white of egg, in small quantity, following the urine, or expelled during the evacuation of the feces, especially when straining is required for this purpose. This symptom causes great alarm to the patient, as he believes that he is suffering from a continual escape of the semen. Such is, however, not the case. I never found any sperm elements in it. It proceeds apparently from the prostate gland; and its presence in sufficient quantity to issue from the urethra is an indication of a relaxed condition of the ducts of the gland, permitting the secretion to be expressed during the voiding of the urine or feces." Dr. King Chambers seems to be of a similar opinion, regarding this discharge as one of pure mucus, which may go on for years without any physical or mental impairment unless the patient's mind is directed to the subject. Mr. Teevan, on the other hand, regards this as "true spermatorrhœa," and curiously enough ascribes it to indigestion. Mr. Benjamin Phillips remarks, "At one time I doubted whether this fluid were spermatic, it is usually so smooth, transparent, and homogeneous; but if it be examined under the microscope, spermatozoa can usually (italics writer's) be observed in it. Its thin character has induced people to think that it was a depraved secretion become watery by exhaustion of the secretory organ; and sometimes it may be so, for if a person who complains of the constant escape of the thinner fluid has an ejaculation, the fluid will be thick and grumous. It is therefore most probable that the more fluid portion of the secretion which fills the seminal vesicles is most easily pressed out; and this is a reasonable explanation of this feature of seminal discharges." Considerable diversity of

<sup>1</sup> I am not forgetful of the fact that Hippocrates describes spermatorrhœa and tabes dorsalis as arising from venereal excesses, *Ἡπὶ τῶν ἐν τῷ κατὰ φύσιν καὶ ἐπὶ τοῦ νοσήσαντος*.

<sup>2</sup> North American Med. Chir. Rev., July, 1860, p. 693.

opinion, it is therefore obvious, exists as to the nature of this discharge, the presence of seminal elements being denied on the one hand and affirmed on the other. Some years ago, in writing on this subject,<sup>3</sup> I expressed the conviction that while in the majority of instances the secretion was entirely from the prostate, yet that facts were wanting to prove that involuntary seminal emission did not so occur, and, indeed, that my experience proved the contrary. Further observation entirely confirms me in this opinion. It seems to me immaterial whether the discharge be called prostaticorrhœa or spermatorrhœa (and if the presence or absence of spermatozoa is to regulate the nomenclature, the microscope will at once determine this), the main question being, whether this is a normal condition, whether it is injurious to health, its causes, and how to remedy it. I do not think it will be maintained that this is a normal condition; neither will it, I suppose, be denied that a constant drain of seminal fluid from the urethra is likely prejudicially to affect the health. In the following cases of prostaticorrhœa two groups are recognisable; in the one spermatozoa existed in the discharge, in the other these elements were absent; while the apparent causes were various, and bore out the propositions enunciated at the outset of these remarks.

Case 1 came under my notice in October, 1880. I have but few notes of this case, being that of a third-year's student of medicine. Patient complained of a frequent discharge of tenacious matter from the urethra during defecation. He felt confident that his health suffered, and he desired my opinion as to the nature of the discharge. Examination of the urethra revealed a certain amount of prostatic tenderness, and the microscope the abundant presence of spermatozoa in the discharge as represented in the subjoined diagram.

FIG. 1.

I advised the passing of a full-sized metallic instrument twice a week, and tonic treatment, requesting that I should be informed if the result were not satisfactory. Not having seen the patient subsequently, nor having heard from him, I infer that his ailment disappeared.

(To be concluded.)

## THE TREATMENT OF GONORRHOEAL OPHTHALMIA.

BY CHARLES BADER,  
OPHTHALMIC SURGEON TO GUY'S HOSPITAL.

THE uniformly favourable success of this new treatment, and the serious nature of the disease, will, I hope, justify the publication of the following cases, which have occurred in the present year. See also THE LANCET for May, 1880.

CASE 1.—Miss S—, aged eight, when seen on Jan. 21st with Dr. Harter, of Artillery-place, Finsbury-square, suffered from gonorrhœal ophthalmia (fifth day) of the right eye, probably through a servant with gonorrhœa using a towel in the child's room. The anæsthetic was necessary for examination, the child being most troublesome; this Dr. Harter had to repeat each time when injecting the ointment.

<sup>3</sup> On the Functional Diseases of the Urinary and Reproductive Organs. Second edition. J. & A. Churchill, London.

The purulent discharge, redness, and swelling of the lids were very great, and even under the anæsthetic only a glimpse of the lower margin of the opaque cornea was obtained. Similar examination on Jan. 24th and Feb. 7th showed the lower third of the cornea opaque. The ointment was injected once daily, and the eyelids kept bound with lint smeared over with it, changing the lint several times during the day. The left eye, which remained unaffected, was only bound up with lint and ointment, taking care to attend to this eye before the other was touched. The injection of the ointment was discontinued on Feb. 7th, when the lids opened sufficiently to see the entire cornea. When the child was seen in March, the surface of the cornea was smooth, and the opacity reduced to a small nebula.

CASE 2.—Mrs. E. B—, aged thirty-four, was admitted into the eye ward of Guy's Hospital on March 3rd, with gonorrhœal ophthalmia of both eyes. The lids of the right eye were too much swollen to admit of a view of the cornea; that of the left eye, on raising the red drooping swollen lid, was found to be transparent. The sister of the ward injected the ointment at 9 A.M. and 4 P.M. daily; both eyes were kept bound up with lint thickly covered with ointment; fresh lint was applied after each injection.—March 14th: Injection of the ointment at 9 A.M. only; the lids open fairly; the lower margin of the right cornea is opaque.—21st: Discharged. Advised to smear some of the ointment among the eyelashes at bedtime.—April 4th: All discharge ceased; right corneal opacity barely noticeable.

CASE 3.—Mr. H—, aged twenty, when seen on April 26th, 1882, with Dr. Blades of Kennington-park-road, was suffering from gonorrhœa and from gonorrhœal ophthalmia of the left eye. No inspection of the cornea was possible, the swelling and tension of the eyelids being too great; there was much purulent discharge, pain, and intolerance of light. Right eye not affected. Dr. Blades injected the ointment daily (about 11 and 4 o'clock) beneath the upper eyelid of the left eye; both eyes were kept bound up with lint and ointment.—April 30th: Less pus and swelling; eyelids of a dark blue-red hue; the lower part of the cornea, as far as visible, opaque. On receiving a telegram the next day that the right eye was also inflamed and discharging, I replied, "Inject both eyes." Five days later the discharge from the last attacked eye had greatly subsided. As the lids opened and discharge and swelling became less, the injection was made once daily, but the bandage with lint and ointment was continued. On May 25th the ointment was discontinued and weak alum lotion used for bathing. In July I saw the patient: both corneæ were clear, and the eyes well in all respects.

Remarks.—The ointment consists of one grain of the red oxide of mercury (supposed to destroy the contagious matter), of one-fifth of a grain of daturin or atropin (to combat iris complications), and of one ounce of vaseline (as the best vehicle to touch and saturate the entire surface of the conjunctiva with the remedies). In no case, however great the

swelling of the eyelids and conjunctiva, has any difficulty been experienced in injecting the ointment. For injection a small glass syringe, figured above, is used (made by Messrs. Krohne and Sesemann) with a flat nozzle, to pass readily beneath the margin of the upper eyelid. The ointment, passing beneath the margin of the upper eyelid, escapes, generally with some pus, at the inner canthus. About two drachms of the ointment suffice for one injection. No pain whatever is felt when manipulating gently.

At a meeting of the Medico-Chirurgical Society of Glasgow, held on the 6th inst. in the Faculty Hall, St. Vincent-street, the following gentlemen were elected office-bearers for the session 1882-83:—President: Dr. W. T. Gairdner. Vice-Presidents: Drs. Robert Grieve and Alex. Robertson. Council: Drs. George Mather, H. C. Cameron, Robert Forrest, Lapraik, D. Maclean, J. C. Woodburn, Wm. Whitelaw (Kirkintilloch), W. A. Wilson (Greenock). Secretaries: Drs. W. L. Reid, and J. W. Anderson. Treasurer: Dr. Hugh Thomson.

## A Mirror

OF

HOSPITAL PRACTICE,  
BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORAGANI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

## GUYS HOSPITAL.

ACUTE ABSCESS IN LUMBAR REGION AFTER INJURY;  
SEVERE PAIN DOWN THE COURSE OF THE ANTERIOR  
CRURAL NERVES TO KNEE; FREE OPENING; NECROSIS  
OF LUMBAR VERTEBRA; RECOVERY.

(Under the care of Mr. BRYANT.)

FOR the notes of this case we are indebted to Mr. Kidd.

Frederick L.—, aged twenty-two, was admitted into the accident ward on Dec 2nd, 1881. Three days prior to admission he fell from a height of about eight feet upon his back. He got up and went on with his work, carrying timber, for an hour. He then left work for dinner, but felt sick. He then walked a mile and a half to the hospital, where his back and arm were strapped up. He walked home and went to bed, and stayed there until Dec. 2nd. His appetite remained good, and he took bread-and-butter and milk. During this time he felt pain across his back, down the front of his thighs, and in his knees (not down the legs). A fortnight before the accident he had pain and stiffness in the left elbow, though he could remember no injury.

On admission there was great pain in the lumbar region, with a slight swelling over the third and fourth lumbar spinous processes, and tenderness on pressure. There was pain likewise down the front of the thighs and knees. There was also a slight bruise over the left olecranon process. Milk diet was ordered.

On Dec. 3rd one grain of opium pill was ordered twice a day; milk two pints and a half. Spongio-piline, with tincture of opium, was applied to the back. He still complained of pain in the knees; movement of the knees was becoming impaired, and there was hyperæsthesia. On the 5th the tongue was red and dry. There was apparently deep-seated pus in the lumbar swelling; the swelling was three to three and a half inches long by about two inches wide. He complained of pains in his knees, but pressure did not perceptibly increase it. Next day there was retention of urine. A deep puncture was made through the muscles into the lumbar swelling, and about an ounce of pus and blood came away. There was an acute inflammation over the olecranon process of the left arm. Lead lotion was ordered. On the 7th fluctuation was detected in the olecranon bursa. The abscess in the lumbar region was further opened, and an ounce and a half of blood and pus came away. The abscess over the olecranon was opened and flaky lymph came away; an internal angular splint was applied to limb. On the 8th patient passed his urine easily. Bowels not opened since accident. A soap enema gave relief. Two days later there was a good deal of discharge from lumbar abscess, and on the 12th the pain in the knees had entirely disappeared. On the 24th the patient appeared to be nearly well. There was very little discharge from the sinus in lumbar region or over the olecranon.

On Jan. 6th the granulations at the elbow being large were lightly touched with nitrate of silver. On the 25th a piece of bone exactly three-quarters of an inch long was found sticking to the orifice of the wound. The exfoliated bone was the result of periostitis, following on inflammation of the ligaments of the lumbar vertebra, probably coming from the spine or lamina of one of the lower lumbar vertebra. The spicules of bone were not sharp.

On Feb. 10th another small piece of bone came away from the lumbar wound. A Sayre's jacket was put on, extending from the nipple to the crest of the ilium. A square hole was cut over the wound. On the 21st the patient was discharged feeling quite well, and still wearing the Sayre's

jacket. The wound in the back was quite healed. His left elbow was rather stiff, but its condition was much improved by gentle movement.

The temperature ranged between normal and 102.5° from Dec. 3rd to the 15th, it then fell to normal, and continued so.

## ROYAL BUCKS INFIRMARY.

DISLOCATION OF THE FIFTH CERVICAL VERTEBRA; REDUCTION; RECOVERY.

(Under the care of Mr. T. H. CEELY.)

FOR the following interesting notes we are indebted to Mr. E. Van Buren, house-surgeon.

Charles K.— was admitted to the infirmary on August 4th with the following symptoms. The history obtained was that he had been loading hay on to a rick, and at the time of the accident was standing on the top of the rick close to the side. The hay gave way, and he fell backwards on to the ground (a distance of between twenty and thirty feet), striking himself on the back of the neck. He was picked up insensible and conveyed in a cart to the hospital.

On admission he was found to be partially insensible. The pupils were both rather dilated, but equal. There was complete paralysis of the upper and lower extremities, and the breathing was slightly abdominal. The penis was in a state of erection, and there was a desire but no power to pass water. A No. 10 catheter was passed and about a pint of urine drawn off. It was clear and acid; sp. gr. 1020, and contained no albumen. The pulse was 64, full, and non-compressible. He gradually became more sensible, and complained of great pain at the back of the neck, and he also said his arms and feet felt cold and numb, and that he had great difficulty in getting his breath. The slightest movement of the head hurt him, and as he seemed to be improving it was deemed advisable to leave him alone, strict abstinence from all movement was enjoined, and sand-bags were placed on each side of the head. Some injury to the upper part of the cervical vertebra was suspected.

In about an hour and a half after admission the man became rapidly worse. The breathing was almost entirely abdominal and stertorous; he was with difficulty roused, and there was evidently paralysis of the glottis as fluids entered the lungs. He began to get much cyanosed, and it was but too palpable that unless something were done, and that something quickly, the lad would die. In Mr. Ceely's unavoidable absence Mr. Van Buren took upon himself the responsibility of acting.

On sitting the man up, and examining the back of the neck, much bruising was present over the cervical region, and evidently some abnormal condition of the anatomical arrangement of one of the cervical vertebra. The seventh was prominent, and could be readily recognised; but the second spinous process above this was even more prominent still, and there was marked displacement of the vertebra. No signs of fracture could be detected, and it is certain there was none of the spinous process.

It was concluded that it was a case of dislocation which should be reduced. The nurse being instructed to steady the head, Mr. Van Buren placed his two thumbs on each side of the projecting spinous process, and with the rest of his hands taking a firm grip of the neck just above the clavicles, and commenced to apply gradually increasing pressure, the nurse at the same time elevating the head slightly. The vertebra went in with a distinct snap, and all prominence and displacement disappeared. The lad at once became quite sensible, and in a very short time the breathing gradually became thoracic. When seen two hours after he could move his legs and arms, and said he felt quite well, only a little sore behind the neck. His temperature was 100° F.; pulse 84. He had no bad symptom afterwards, and eventually left the hospital in capital health.

*Remarks.*—That cases of this kind are rare no one can deny. In fact, Sir Astley Cooper went so far as to say they could not occur; but that the one narrated was a case of dislocation I honestly believe. I have wished to put this case on record, because there is a great tendency to give up all hope if the neck is seriously injured. I trust this case will show there is a *dernier ressort* which may do good, and at the least can do no harm.

## LIVERPOOL LOCK HOSPITAL.

(Under the care of Mr. A. BERNARD.)

THE following notes of cases of warty growths on the genitals may prove of interest.

CASE 1. *Phimosis*.—On compressing the forepart of the penis a hard mass was felt simulating induration of the glans. A few small warts at the free border of the prepuce led to the belief that the induration was due to the presence of warty growths, which was confirmed on freely dividing the foreskin, an extensive crop of warty excrescences becoming exposed attached to the under surface of the prepuce, furrow, and glans penis. A strong solution of liq. plumbi was applied for a few days with the hope of drying up the growths. As this was not satisfactory, it was decided to remove them by means of the thermo-cautery, under the administration of chloroform. By this means all the growths were carefully removed, and afterwards attended with but very slight pain for a short time. The cauterised surfaces healed in a fortnight. This patient came under notice six months afterwards, the penis showing no trace of the excrescences.

CASE 2. *Phimosis, complicated with ulceration and perforation of the prepuce, the glans protruding*.—Upon drawing the glans through the perforation a few warty excrescences became visible, fetid pus exuding. The prepuce felt very hard on pressure. The only indication was to remove the fore parts of the prepuce, chloroform being administered in this case also. On removing the prepuce a crop of warty excrescences, situated similarly to Case 1, became visible. These were all ligatured. The patient was discharged cured in fifteen days.

CASE 3.—Female patient affected with an extensive crop of warty excrescences situate on the labia majora, and extending backwards, occupying the greater part of the perineum. Removed by means of the thermo-cautery, under the administration of chloroform. Discharged cured in three weeks.

CASE 4.—Elongated left nymphæ extensively hypertrophied at the lower half, which was thickly studded over with hard warts. Expectant treatment with local applications having failed to restore the nymphæ to its normal appearance, the hypertrophied part was removed with the bistoury, the thermo-cautery being applied to the cut surface to allay hæmorrhage, which it did most effectually. This patient was discharged cured in twenty days with little to distinguish the affected nymphæ from the sound one.

CASE 5.—Thick warty growths on the glans, prepuce, and furrow, giving to the parts a most unsightly appearance, situated on broad bases, and of some months' duration. Removed with curved scissors, perchloride of iron being immediately applied to check hæmorrhage. This patient was discharged in three weeks with nothing to indicate his previous affection.

CASE 6.—This case was admitted to hospital on Sept. 12th, 1882, suffering from phimosis with ulceration and perforation of the prepuce, the result of irritation set up by the pus exuded from warty excrescences situated on the inner surface of the prepuce, furrow, and glans. The aperture of the prepuce was very small owing to congenital phimosis. A bunch of warty excrescences protruded through the perforation, and a small wart at the aperture. The prepuce was freely divided under the administration of chloroform, and the growths, which were numerous, were removed with curved scissors. Very slight bleeding. Perchloride of iron was applied similarly to the last case. This patient was discharged, at his own request, on Sept. 22nd, all but well.

Mr. F. W. Lowndes administered the chloroform in all these cases.

THE HOWARD MEDAL.—The Council of the Statistical Society announce their intention again to grant the sum of £20 to the writer who shall gain the above medal for 1883, essays for which must be sent in on or before June 30th next. The subject is "The best Exposition of the Experiences and Opinions of John Howard on the Preservation and Improvement of the Health of the Inmates of Schools, Prisons, Workhouses, Hospitals, and other Public Institutions, as far as Health is affected by Structural Arrangements relating to supplies of Air and Water, Drainage, &c."

## Reviews and Notices of Books.

*Clinical Lectures on Diseases of the Nervous System.* By THOMAS BUZZARD, M.D. Lond., F.R.C.P., Hon. Fellow of King's College, London; Physician to the National Hospital for the Paralysed and Epileptic. London: J. & A. Churchill. 1882.

## [SECOND NOTICE.]

If anyone wishes to be cured of a habit of taking too narrow a view of tabes dorsalis, we specially commend these lectures to him. He will find in them due attention given to tabetic symptoms so different as optic nerve atrophy, herpes with lightning pains, a certain joint disease, and gastric crises, as well as to the two especially important diagnostic symptoms—absent knee jerk and the Argyll-Robertson phenomenon. The question as to the influence of syphilis in the causation of tabes is considered at some length. As from a therapeutical point of view this is a most important matter, we quote Dr. Buzzard's brief summary of a lengthy consideration of the facts. He says (p. 214): "Whilst it appears to me incontestable that there is a remarkable frequency of association between syphilis and tabes dorsalis, I do not think, all things being considered, that the time has yet arrived for us to draw safe inference as to the precise nature of the relation."

The following quotation gives the author's view of the pathology of "gastric crises" in tabes, and embodies, too, some facts corroborating his well-known hypothesis as to its physiology and pathology. The importance of the subject justifies a long quotation:—

"In a communication brought before the Pathological Society of London in February, 1880,<sup>1</sup> I made the suggestion that gastric crises depend upon irritation of the nucleus of the vagus by sclerosis. At that time I had no anatomical evidence to offer in support of the hypothesis, which was based upon the paroxysmal character of the attacks, so completely in accord with that characterising the attacks of lightning pains. It appeared evident to me that if sclerosis, which when it attacked nerves of common sensation produced pain, came to invade the nucleus of the vagus, it might be expected to give rise to symptoms like those of the gastric crises. During the meeting of the International Medical Congress in London, 1881, Professor Pierret, of Lyons, showed me sections of the medulla oblongata which he had recently made from a case of tabes with gastric crises. I was greatly interested in his demonstration that the fasciculus gracilis in immediate relation with the nucleus of the vagus exhibited distinct sclerosis. It will be remembered that the funiculus cuneatus and gracilis, which closely adjoin the sensory portion of the pneumogastric nucleus, represent the continuation of the posterior columns of the spinal cord upwards to the cerebellum through the medulla oblongata." Dr. Buzzard adds in a footnote: "Whilst this work is going through the press I note a paper by Dr. Emile Demange (*Revue de Médecine*, No. 3, Paris, 1882) on the 'Chute Spontanée des Dents, et Crises Gastriques et Laryngées chez les Ataxiques.' In a case marked by spontaneous shedding of the teeth (without caries), and also by gastric and laryngeal crises, histological examination of the medulla oblongata showed the greater part of the nuclei of origin of the bulbar nerves plunged in the midst of sclerous tissue. The nucleus of the mixed nerves (glossopharyngeal, vagus and spinal accessory), as well as the ascending root of the fifth and other structures, were evidently involved in this sclerosis. The signs of sclerous neuritis were observed in the branches of the fifth nerve."

About fifty pages are devoted to one tabetic symptom, not more than its importance deserves, to what the author calls "Charcot's joint disease" in tabes. In this country Dr. Clifford Allbutt was the first to draw attention to this morbid affection in tabes; later Dr. H. Thompson published a case; then follow Dr. Buzzard's observations. We strongly commend the four lectures on this form of joint disease to

<sup>1</sup> Transactions of the Pathological Society, 1880.

the attention of surgeons. They embody as important a contribution to surgery as they do to medicine. The author shows that in spite of its rarity it has as much right to be included in the symptomatology of tabes as any other symptom, whether striking or not striking. He relates several cases, and in addition makes the following general remarks:—

"Experience of these cases shows that with a striking similarity in their onset, their progress varies. In some, at the end of a few weeks or months, the swelling disappears, and the joint apparently returns to its former condition. In others, on the contrary, grave disorder remains—erosions of the osseous surfaces, creaking movements, various luxations, or even total destruction of the joint. As regards the order of frequency, it is first the knee, then the shoulder, the elbow, hip, and wrist, which are apt to be affected. Several joints may be coincidentally involved."

Dr. Buzzard has pointed out that there is a remarkable frequency of association of tabetic arthropathy with gastric crises. "The cases of tabetic arthropathy that I can find recorded (including nine of my own) number forty-eight. In twenty-four there were gastric crises," (p. 266). This is certainly a very striking proportion. If further evidence confirms Dr. Buzzard's opinion he will have enriched medical science with a generalisation of great value. He believes that there is a nerve centre in the medulla oblongata concerned with the nutrition of bones and joints, and thinks the "lesion of a structure adjacent to the nuclei of the vagus may be found to explain the osseous affection in tabes."

There is another matter of great interest to surgeons as well as to physicians, Dr. Buzzard writes (pp. 273 and 274):

"It has occurred to me to see one patient in whom the presence of a stone in the bladder led me to examine the state of the patellar tendon-reflex. It was found to be absent, and inquiry elicited the fact that the patient suffered from most characteristic lightning pains. I would suggest that tabes may be an occasional source of origin of a calculus, of the kind which Sir Henry Thompson calls 'local,' in contradistinction to the calculus (as—e.g., uric acid) which is of 'constitutional' origin. In many cases of tabes, at an advanced stage, there is actual paralysis of the bladder. But a certain amount of difficulty in expelling urine may be a very early symptom, dependent probably upon vesical anaesthesia and absence of normal reflex. It will often be found, on inquiry, that the patient never has the natural feeling of wanting to pass urine, and does not know when it is being voided, or when he has finished. In such circumstances, unless he contracts the habit of passing it at regular intervals, there is always the possibility of cystitis occurring from urine getting retained, and in the mucous of the bladder; in these circumstances, a phosphatic calculus may easily be formed. It is worth while remembering that a bladder trouble of this kind may be as prominent and absorbing a symptom as either the gastric crises or the optic atrophy; and if ataxy of gait be absent, the real nature of the trouble may be easily overlooked. I have but little doubt that not a few cases of atony of the bladder for which the surgeon is consulted are examples of tabes with the bladder trouble predominating." He adds in a foot-note (p. 274): "At the International Medical Congress, held in London, 1881, Sir William Gull, President of the Section in which the substance of this lecture was read as a paper, expressed his opinion that the position here taken as regards stone in the bladder was sound, and remarked that the case of the late Emperor of the French was one which, according to his belief, went in support of my view."

In Lecture XVI. he tells us that, "There is a kind of stupor which is a noteworthy feature in many cases of intracranial syphilis." After his usual clinical method, he illustrates by a case, describing the particular symptomatic condition in his narration of it. He does not glibly pass over its pathology as being "caused by syphilis," leaving the process of causation out of focus. Most syphilitic nervous symptoms are indirectly owing to syphilis, as the author believes the one he is dealing with to be. His in-

ference as to its pathology is that the cortical substance of the brain is "starved of blood to a considerable extent" by syphilitic disease of the cerebral arteries. "We can easily conceive," he suggests, "that this starvation may stop short of death of the tissue—that is to say, there may not be absolute obstruction and consequent softening, but a state of partial atrophy." Thus it will be seen that he distinguishes, as indeed he does expressly further on, the condition he supposes to exist from that of local cerebral softening owing to actual thrombosis of syphilitic arteries. The happy fact of his patient's recovery leaves, the author admits, the pathology of the case he adduces hypothetical. The opinion of this physician on the treatment of any variety of cerebral syphilis deserves most respectful attention; we gladly give space for it. The matter is of grave clinical importance. Here is what Dr. Buzzard has concluded as to the relative values of the iodide of potassium and mercury in the treatment of cerebral syphilis. Referring to the case alluded to, he writes (p. 289):—

"B—, it will be remembered, had been taking thirty grains of iodide daily for two months, when he broke down in his brain. This drug, then, supposing the view taken of the man's pathological state to be correct, had failed to influence the new formation in the arterial walls, so as to prevent the grave consequences of narrowing and thrombosis. No doubt there is the probability that its administration was commenced too late; that changes had taken place in the growth such as rendered its absorption (which might have been practicable at an earlier stage) no longer likely to happen; and there is the possibility also that the dose was not large enough. But it is a fact, however it is to be explained, that we very often meet with this condition of thickened arteries in the post-mortem examinations of persons who have been taking iodide of potassium up to the time of their death. I have long had a rather strong impression that the iodide has comparatively little effect upon this arterial change, and that it is best to employ mercury without delay in most cases of this kind. At all events, under a really effective use of this drug (administered by inunction), the restoration to health which took place in these patients was most striking. It is not unfair to suppose, although it cannot be proved, that under its use a good deal of the new growth in the arterial walls, which had resisted the effects of the iodide, was absorbed, so that the channels of circulation became gradually liberated to a great extent."

Lecture XIX is on paralysis agitans; and since its diagnosis from disseminated sclerosis is therein carefully considered, we may say that it is partly on the latter morbid affection also. We must refrain from dwelling on more than one part of this excellent lecture. There is an entirely novel observation which is of great interest in several different ways. Speaking of the alteration of voice in one of his patients suffering from paralysis (agitans, Dr. Buzzard writes (pp. 334-335):—

"We all know that on the stage peculiarities of every kind are obliged to be accentuated for the sake of strong light and shade. When a very advanced period of old age has to be represented, the tone of voice adopted is exactly of the shrill piping character which we note in this woman, who, however, is only sixty-two years of age. Shakespeare thus refers to this character of voice in connexion with the sixth of his 'Seven Ages of Man':—

"His big manly voice,  
Turning again towards childish treble, pipes  
And whistles in his sound."

Since I first noted this piping note in cases of shaking palsy I have been interested in observing whether it was common in the exceptionally aged persons, not afflicted with paralysis agitans, whom from time to time I have met. I have not found it to be so. Now, paralysis agitans, although, as Charcot has pointed out, it especially assails persons who have passed their fortieth or fiftieth year, has a slow march and little or no tendency to curtail longevity. Hence there is always to be found a certain number of persons afflicted with paralysis agitans who have arrived at a ripe old age, and who present this peculiarity of voice. I cannot help thinking that the conventional voice of age on the stage has originally been derived from the study of some

old person affected with this disease, and thence handed down, as we know is the stage custom, to successive generations of performers."

Dr. Felix Semon examined this patient laryngoscopically, but discovered no abnormality.

The rest of the work deserves as much notice as has been given to the lectures we have already remarked on, but the demands of our space leave us no choice but to do little more than mention what remains. There is no separate lecture on diphtherial paralysis, but in many parts of the work the author deals with it in a very realistic manner. There is an admirable lecture on "Ophthalmoplegia Externa, with Tabes Dorsalis," with an elaborate and excellent examination of the parts diseased, by Bevan Lewis. If anyone wishes to realise that scientific research and what Carlyle calls "practicality" may be combined without confusion, he will, by reading this lecture, see that it can be thoroughly well done. From Lecture XXIV. the reader will find that fourteen years ago (*Practitioner*, October, 1868) Dr. Buzzard drew attention to the phenomena of "transfer" induced by encircling blisters placed on limbs above the point of departure of the so-called epileptic aura. This was some years before the well-known experiments on cases of hysterical hemianæsthesia by Charcot and others. Thus Dr. Buzzard was prepared to think, from what he had previously observed himself, that such transfer was very probable, and that there were no good grounds for doubting the *bona fides* of the hysterical patients.

OF

## INTRODUCTORY ADDRESSES

DELIVERED AT THE

## PROVINCIAL SCHOOLS OF MEDICINE

AT THE

Opening of the Session 1882-83.

### COLLEGE OF MEDICINE, NEWCASTLE-ON-TYNE.

ADDRESS BY DR. THOMAS OLIVER.

THE lecturer took for his subject "Medicine, its Progressiveness and Relation to Civilisation." After a few words of introduction Dr. Oliver said:—"The existence of the science and practice of medicine is a necessity. Its origin is shrouded in mystery. To understand the causes which led up to the origin of the art, you must go back with me to a time when this earth was peopled by masses of rude men and women; to a time when lawless hordes roamed about, owning no habitation but the face of nature, and bound to each other by no tie save that of the social instinct. Civilisation, or, in other words, the development of these masses, could only arise through differentiation of the individuals. . . . From the peculiar nomadic character of primitive tribes, the art of surgery must have preceded that of medicine. As, in the world of life, no development takes place, no organisation is accomplished without interdependence of parts, so, in the development of society, special men were set aside to do special work, different duties were allocated to different individuals; and each one, trying to do his own work aright, was unconsciously contributing to the improvement and elevation of his fellow-men. In the social as in the physical world, kosmos succeeded chaos, and, with the growth of society, the requirements of men became greater. From being pastoral in their habits, and predatory in their inclinations, men of the Indo-European race after a time became settlers. I am not in a position to tell you how disease originated. It is not necessary to believe with Plato that it was due to the degeneration of man, for these primitive people were living under the freest of conditions, under conditions which harden rather than

lead to degeneration. It may be that disease originated then, as it does now, in repeated violation of the laws of nature, or was part of that Almighty fiat which said, 'Let there be life,' or, as moralists tell us, was a visitation for some sin. Once originated, however, it formed one phase of social life which had to be dealt with, and requiring treatment at the hands of the tribal physician. The origin of the art of medicine, then, if this summary is correct, presupposes a higher state of the social mass for its reception than the origin of surgery. Observation of disease, and the results obtained by means of the treatment adopted, led to the recognition of antidotes, and to their classification. Out of observation and experience arose the practice of medicine. From the nature of things, men were contented with results for some time before they attempted finding out the reason why. It was when the faculty of reason was brought to bear upon the questions at issue that medicine developed from an art to a science. There could not have been in those early days, more than there is at the present time in Central Africa and some of the Oceanic Islands, anything like a well-arranged system of medicine. Empiricism, trading upon ignorance and superstition, was the condition of medicine until late in the development of the Continent, and in this condition it remained until Greece asserted her influence. It is true that the early Egyptians were not altogether unacquainted with the efficacy of medicines; but, so far as our inquiry is concerned, Egypt at this period, though far advanced in civilisation, is only interesting to us as being the source whence the Greeks got their information. Simple in their manners, severe in their laws, and careful in the education of youth, the Greeks soon rose to fame. They recognised the fact that to be great they must be learned; and yet, while the Greeks recognised the great influence of culture in almost every department of life, while the nation was being consolidated at home and extended abroad, and its language becoming almost universal, the science of medicine had made little or no progress in their hands. And how was this? The rise of the nation was very rapid; plenty had too easily replaced want, and in that way damped the enthusiasm and aspirations of a noble people. The Greeks, overcome by pride and satiety, failed to push forward the good works they had begun.

"As for medicine, how could it develop? Like the other sciences, it had been carried to the temples, where, for a time, it was practised by Æsculapius and his followers. Æsculapius, who has been called the god of medicine, was a man with a wonderful reputation. With his two sons he founded a system of medicine, the followers of which were called Asclepiadæ. But, with Æsculapius, as with all founders or originators of systems, his pupils, in their attempts to further the development of that system, simply distorted it to meet their own ends. They built temples to the god of medicine in healthy situations—buildings surrounded by everything that nature could give to refresh the sight of the sick; and, internally, as in our modern hydropathic institutions, these buildings contained everything to make a residence within them pleasant and agreeable to the invalid. The external application of oil and water were the hygienic remedies employed; but, in addition, the Asclepiadæ were bold enough to make use of harsher measures when the occasion required them. These men, however, saw that they had a monopoly in their hands. Somehow or other a kind of sacred feeling came to surround these temples, wherein prayers were offered up by the priest-doctors, and fasting advised; and, recognising the influence of the moral on the physical, they took every opportunity to impress their patients that a cure to their disease could only come from the god of medicine, whose messengers and interpreters they were. Forming, in this way, a separate class, and transmitting their medical knowledge from one to another, as a family heritage, the Asclepiadæ followed their practice in profound secrecy.

"In the temples of Æsculapius, medicine made little or no progress—none, at least, so far as we know, until the Asclepiadæ revealed the secrets of their practice to those who had undergone a process of training. Medical instruction may thus be said to have originated in the temples. It could not be without its advantages to the Asclepiadæ, for the fact that their actions and lectures were criticised by younger men must have forced them to exercise the faculty of reflection. The most we can say of the Asclepiadæ is that they attempted exactness in their practice; they took notes of cases, and classified symptoms; but they seldom discussed the

origin of symptoms. That duty, and with it we may trace the rise of the real art of medicine, was left to those who rescued it from the temples, and foremost amongst the Greeks stands out Pythagoras. Close upon Pythagoras comes Hippocrates, one of the greatest writers on medicine. To him is attributed the statement that health depends upon an exact proportion of the four cardinal elements of the body—blood, bile, phlegm, and black bile, a doctrine which constituted the ancient system of 'dogmatism,' and which was taught, with few exceptions, until the foundation of the schools at Alexandria. Hippocrates was a simple observer, and an accurate recorder of facts. Amongst his pupils, however, dissensions arose. Methods and theories were thus attributed to Hippocrates which were never his.

"The art of dissection, and the facts recorded by Galen, gave a great impulse to the study of medicine. At this time, however, Alexander the Great was at the height of his glory. Successful in his wars abroad, Alexander had enriched his native country by the treasures he brought home. But it was left to one of his generals named Ptolemy to complete his work. Ptolemy recognised the secret of Grecian development, and, wishing to be great like his master Alexander, he saw that this could only be accomplished by making mind the moving force. For this end he gathered around him the intellect of the day. Philosophers and mathematicians now made their way to Alexandria, where medical schools sprang into existence, which soon eclipsed those of Cos and Pergamos. In the details of the study of practical anatomy the Alexandrians were well versed, and, for a time, all went well. As Alexandria acquired intellectual renown, so, in like degree, prospered the science and practice of medicine; but an evil day came. As in the earlier days of Greece, the people were not content to live in obedience to law, so in Alexandria, when it reached the height of fame, its statesmen and its scholars no longer observed and studied facts for themselves. The art of dissection fell into disuse, research was no longer stimulated, and science ceased to advance. It is true that Galen, by his writings on anatomy, has shed a lustre on the Alexandrian epoch. Much of his teaching, and much of the teaching of the schools was carried back again to Greece. Meanwhile, Alexandria was rapidly falling into decay. Rome, now in the ascendant, was travelling eastward. Julius Cæsar burnt the great library, and, for a while, the ruin of a marvellous city was all but complete. . . . Soon after the Mahomedan conquest of Egypt the Alexandrian library, which had been restored, was again destroyed. To the extent, however, that the Saracenic empire was enriched by the capture of Alexandria, so was that empire and the other nations impoverished by the rash order of Amrou. Mussulman princes invited men of learning to settle amongst them, and of these not a few were zealous students of Greek philosophy. Into many Mahomedan families the Jews gained access in the character of physicians. This contact refined the Mussulmans, for soon their fanaticism abated, their manners became polished, and their thoughts elevated. They ranked first amongst the commercial nations of the world, and were far ahead of all in science and philosophy. Under a system of freedom in education and physical research the Saracenic empire kept extending in every direction. Great in territory, it was also great in education, for in nearly every part of this large empire colleges existed. In the schools of medicine good work was done by these Arabians, especially in the departments of materia medica and pathology. Alexandria no longer occupied the prominent position which had been hers for centuries; but ere she entered on her decadence she gave that stimulus to progress which has not yet spent its force in Western Europe.

"It is a long time from the epoch during which the Universities of Europe sprang into existence, such as Bologna, Paris, Salamanca, and Oxford; and while it is true that for generations their work was carried on in comparative quietude, and the results of their teaching unfelt, their influence is now seen in that general diffusion of education which is the crowning glory of our age.

"Soon after the art of printing was revived, the art of engraving came into use, and, by its means, the practical study of anatomy and physiology was facilitated. With the revival of letters, physicians turned their attention to the means of preventing, as well as curing, disease. Harvey, at this time, had discovered the circulation of the blood; and, though his views were only a modification of Galen's, they simply revolutionised physiology. Like every new discovery,

however, it was long in being adopted. The teachings of antiquity could not be overthrown at once. For twenty-five years Harvey maintained in the face of great opposition what is now the chief fact of physiology. Following in the train of medical discoverers, comes Malpighi, who demonstrated by means of the microscope the existence of corpuscles in the blood; then Asselli, who discovered the lymphatics—a discovery which the two Hunters showed to be more comprehensive than Asselli ever dreamt. Medicine was now a preventive as well as a curative science. The hospitals built in earlier days were no longer fit receptacles for the sick. Hygiene was not sufficiently understood to enable physicians to deal satisfactorily with the disposal of large masses of men and women. Epidemic disease had again and again played sad havoc with our soldiers and our prisoners. For the diminution of such evils as prevailed at this time we can point with true pride to the labours of one man, who made public health his special study, the welfare of his fellow-men a life's work—I refer to John Howard. Small-pox had decimated the masses on more than one occasion, and, for the diminution of its mortality, we are indebted to Lady Wortley Montague for inoculation, and to Jenner for vaccination.

"It is unnecessary to trace the progress of medicine further. With men like Cullen, Boerhaave, and Corvisart medicine made steady progress, and the close of the eighteenth century saw a system of clinical teaching revived, more brilliant and more glorious in its results than that which had fallen into disuse two thousand years previously. What medicine of the nineteenth century has done, and has still to accomplish, writers of succeeding generations may record. Much has been done; much still remains to be accomplished. Just at a time, however, when civilisation is at its highest, and scientific men had renounced everything for the investigation of the more hidden causes of disease and their means of treatment, their hands are tied by Parliamentary interference. Not to destroy life, but to save it, is our motto; and if to accomplish this the lower animals are made the basis of considerably conducted experiments, how great is the gain to man and to the animals themselves."

#### QUEEN'S COLLEGE, BIRMINGHAM.

ADDRESS BY DR. RICKARDS.

AFTER a few introductory remarks, Dr. Rickards gave an outline of the history of the Medical School, which was started in 1828 as the Birmingham Royal School of Medicine and Surgery. The local medical activity, instrumental in its first formation, led to the creation of a second school in 1851—Sydenham College. The two institutions, having served their purposes for many years, became in 1868 merged into one—Queen's College. In 1873, for the purposes of clinical teaching, the practices of the General and the Queen's Hospitals were amalgamated, and students were required to attend each hospital alternately for six months. This arrangement gave them the opportunity of seeing the practice of the staffs of both hospitals, and enabled them to cull their experience from the widest possible field. During the past year a change had been effected in the medical department of Queen's College. An arrangement had been made for its students to receive the strictly scientific part of their education at Mason's College. It had been urged against provincial medical schools that they were unable to offer their students advantages equal to those of the metropolitan schools, and therefore decoyed students from the best education; but Birmingham, he thought, need not shrink from comparing its school, as at present constituted, with any in the United Kingdom. There was one disadvantage under which its student who purposed taking the degree of Doctor of Medicine still laboured. He had to go elsewhere to pass his examinations, and was even obliged, in some cases at any rate, to complete a period of residence and a course of study at another medical school before he was allowed to present himself for examination. This was why the local medical profession was directly interested in the establishment of a university in the town. Already there were in Birmingham a number of institutions devoted to higher education, each with its staff of professors engaged in teaching literature, languages, mathematics, natural science, fine arts, theology, and engineering. Surely these institutions might in some way

be affiliated so as to make the possibility of a university in Birmingham no mere dream. He then proceeded to speak of education, especially in reference to the medical calling. He thought the time was coming when the teaching of natural science would take the place of that of the dead languages in the education of those who were not going to make literature their business in life. In the middle and upper class schools the boy's mind was already so taxed as to admit of no further strain. The direction of any change in his education must rather be towards altering the subjects taught than in adding to his school hours. He considered that, as regards the training of the mind to such habits as those of rapid thought, quick observation, fixed attention, sound reasoning, the teaching of natural science would surpass that of the dead languages, and that the other requisite mental training might be acquired by the study of modern literature, with the help of a knowledge of modern languages. He maintained that by the use of the dead languages as the chief means of training the minds of the young, an amount of time and brain power was expended which would be of the greatest possible value if applied to the study of subjects more directly connected with future careers. The early teaching of natural science would not only prepare the mind for a more complete study of its various branches, but would create a desire for advanced scientific knowledge and for the prosecution of scientific research. He thought that, on the grounds of political economy, natural science should not be restricted to the few, but should be widely taught in public schools. He quoted Professor Huxley: "I weigh my words when I say that if the nation could purchase a potential Watt, or Davy, or Faraday at the cost of £100,000 down, he would be dirt-cheap at the money," and remarked that the more labourers there were in the field of science, the greater would be the probability of getting a potential Watt, Davy, or Faraday. The lecturer went on to say that when a student entered a medical school he ought to have acquired a sufficient knowledge of such sciences as physics, chemistry, and biology (not including human anatomy and physiology); that the time usually spent in the medical curriculum was sufficient only for the more strictly medical studies; that under the present system sufficient time was not spent by the generality of students in the wards of the hospitals. In speaking of the modern method of clinical research, he pointed out the value of certain medical appliances. The introduction of the stethoscope, the microscope, the laryngoscope, the ophthalmoscope, the sphygmograph, the clinical thermometer, while facilitating correct diagnosis, had considerably augmented the labour of the student, and had made it imperative that he should devote more time to clinical work than formerly. But, he continued, the student had other objects in view in the wards than fitting on the medical armour for diagnosis—he had to learn the treatment of disease, and here he would find the greatest gap in the science of medicine which had to be bridged over by art. No amount of talent, no bookwork, no systematic lectures, could take the place of bedside study in learning the art of treatment. The student must watch the experienced artist at the bedside. Turning to the students, Dr. Rickards said they were on the threshold of a noble profession. Other callings ministered to the wants of man when in the enjoyment of that greatest of all blessings, health; there came, however, a time when all that he possessed, all that he enjoyed, his ambition, his hopes, his plans were all under a cloud. That was the hour of sickness. It was then that they would be called upon to perform the noblest actions which could fall to the lot of man: to combat disease in all its hideous forms, to ease the pain-racked frame, to succour the dying, to console the survivors, were only some of the sacred duties they would have to fulfil. It was a profession which necessitated much self-sacrifice and even risk to life; the battlefield, the hospitals, the crowded alleys of towns, all in their different ways echoed this truth. They would have to work day and night, paid and unpaid, with appreciation and without it. It was a benevolent profession; to it many of the "medical charities" owed their origin; nor was it unmindful of its own; the medical benevolent societies might prevent any medical man, his wife, or children from being destitute. The profession, though rarely leading to the accumulation of fortunes, assured a comfortable competency to all its members, the demand and supply of medical assistance was so evenly maintained that none need be idle. He advised the students to work regularly and methodically so that they might not have to resort to the "cramming"

system; they should be advised by their seniors. As to their working capacity, they ought not to overwork, squeezing two days' work into one; the midnight oil had put many a prizeman into a premature grave. He urged upon them the importance of practising putting their thoughts on paper and of cultivating the memory by learning by heart and reciting. He begged them not to let a mere diploma be the goal of their medical curriculum, but that their grand object should be to fit themselves for the grave responsibilities of practice.

### LEEDS SCHOOL OF MEDICINE.

ADDRESS BY MR. JAMES WALKER,  
LECTURER ON PRACTICAL PHYSIOLOGY.

ADDRESSING himself specially to the younger students, the lecturer impressed upon them the importance of recognising the fact that they had left school by beginning at once to think and act as men; nay more, as gentlemen and Englishmen. The profession they were about to join, he pointed out, adapted itself so to different tastes that a man could hardly fail to find some opening for his particular bent. After throwing out various other suggestions, Mr. Walker proceeded as follows:—"Your first two years ought to be nearly entirely devoted to anatomy and physiology, or the subjects which are required for the first professional or intermediate examination of the College of Surgeons. Anatomy, being the groundwork or mainstay of surgery, is perfectly indispensable to everyone entering the profession; and to most people, after the first natural aversion and dislike has been overcome, the subject becomes very interesting, or even fascinating, partly on account of its being so thoroughly and completely worked out and understood, for we may say that we now know nearly everything that can be known certainly in ordinary anatomy; and also it illustrates at every turn and in so many different ways, by its beauty and evidence of design, the omnipotence, and even the very existence of the Creator, if such could be necessary. It also has a personal interest to many, for I think most of us like to know as much about ourselves as possible, especially if the knowledge does not happen to be of a disagreeable kind. The only way to acquire the subject is by patient, regular, and persevering practical work in the dissecting-room. Physiology—under which head is now included, somewhat wrongly, the subjects of histology, which is nothing more than minute anatomy, and histochemistry, or chemistry of the tissues—is a subject not so definite and settled at the present time as anatomy, but still so extremely necessary and of such vital importance to the medical world that one hardly knows how or where to begin to advise you for the best, and give you a liking for this most generally necessary of the introductory subjects. It is certainly, as I think no one will deny, at the very root of all treatment of disease, and the groundwork of all rational medicine. It should strike everyone that before you can treat or correct what is wrong in any subject you must know as far as possible the original and healthy condition first, or you are liable and very likely to do more harm than good in your attempts. Whether it is worse, I should like to know, for that is what the question really resolves itself into, to experiment upon living human beings—perhaps your friends and relations—which would happen generally when they are more or less helpless with their feelings, morbidly exaggerated and excited by disease; or to try to find out the same thing through the lower animals, whose nervous system is not so highly developed, and in which case nearly always the animal is rendered insensitive to both mental or bodily pain? It behoves everyone, especially the student of medicine, to look around him and acquire the habit of studying human nature for himself from the reality, and not from books or other people. I remember the late Mr. Nunneley, when I was a student, telling us in a lecture that very early in his career he formed the habit of constantly trying, as he went along the street, to diagnose and make out what ailed people as they passed, and he said that it had been to him a great help in his after-life and training for active practice, often saving much time at very critical moments. He did not do it in any spirit of inquisitiveness, but to aid and cultivate his powers of observation. And I think no one who knew him well will deny that he became a keen reader of character, an acute diagnostician, and first-rate surgeon for his

time. Physiology, as I have said before, has made such rapid strides of late that it seems to have invented or opened up to the profession, and brought very prominently before the public, many new branches for special and more extended work and research. Formerly the only specialists were the pure consulting physician and surgeon (excluding, of course, the arrant quacks who are now being bowled out of existence), and even these were hardly recognised until very recent years in this district. They certainly did not take the same place and standing that they do now. But I think the day is not far distant when the truth will be recognised that for economy of labour and to gain better results in practice it is necessary to divide the profession, which is now too wide for any one mind to grasp, into several subordinate sections. You hear men, from interested motives, exclaiming against the tendency as damaging to the profession at large; but this false and mistaken conservatism—so called—if carried too far, is liable to set up and foster all manner of foul excrescences from the profession, which cannot be got rid of without entire separation and loss to the Faculty in dignity and everything else. It should be the object rather to encourage men at the top of the profession, who have gone through a previous general training, to take up special subjects for which they may have a liking or natural aptitude, than that the public should be imposed upon by men from the other end, or perhaps outside the profession altogether. Physiology is also the foundation of all sanitary science, and so much has lately been done in this direction, and that not always the best, from ignoring or want of knowledge by the acting authorities of often the most elementary rules, that I have only to draw your attention to it and ask you (if interested) to refer to the press, both medical and lay, which at the present time teems with what are thought by their authors to be practical and useful suggestions, and abounds with addresses to learned bodies. There are so many different examining bodies open as an entrance to the profession, that it is difficult for those who do not know much about the subject to choose and settle which diploma to go in for, and especially if they have no knowledge of their value and status, or have no fixed ideas as to their probable future line of practice. It is the general rule at our school for all men to take at least the College of Surgeons' membership for the surgical qualification, and for medicine either the licence of the London College of Physicians or Apothecaries' Hall. These are very good, entitling men to practise in any branch. But I should like the Leeds School men to look upon these rather as the minimum test, and aim at higher things. There is at present, I believe, a Royal Commission sitting, taking evidence as to the quality of the different boards, which promises to do great good. It has shown so far that two of the Scotch licensing bodies or colleges, which give grand sounding titles, are, to say the least, very inferior, and easy for anyone to get, and misleading to the general public. There is no excuse, in my opinion, for our men not taking an English degree who have the means. And I hope all of you would despise the man who, in order to deceive the public in his own interests, or from concerted motives, under the term by courtesy or sufferance, would style himself doctor, or even use M.D. on his door-plate, when he has no moral right; aping at the highest honours when really he has only taken the lowest degree possible. Another rock to avoid, which fortunately now is not so common, is for young men to start practice on a single qualification, which is generally the surgical one, and never take another, the excuse being, and often rightly, that they have no time to work for it. This fault lately has been to some extent cured by the College of Surgeons and Physicians introducing the subject of medicine in one case into their examination for those who have a degree, and so giving, as it were, a double qualification; and now, before a man can get his diploma to practise, or enter his name in the Register, he must have shown fitness in both branches. Besides, there are many appointments, both public and private, where two qualifications are a *sine qua non*; so let me urge upon you the importance of not stopping your school work, as I will call it, until you are fully equipped. Men at the Leeds School cannot blame the school for want of opportunities of acquiring a good, sound, and useful professional education. The school buildings and staff have been lately added to, and made as perfect as possible for teaching, especially in the practical courses; and it is hardly necessary for me to say that with a fine institution and building like the infirmary, with its many unrivalled advantages, the staff of

which is widely acknowledged to be so able, and deservedly looked up to, we should be able to keep up our former reputation, and compete favourably with any teaching institution in the kingdom."

## PROFESSOR PACINI ON THE CLAIMS OF HARVEY AS THE DISCOVERER OF THE CIRCULATION OF THE BLOOD.

To the Editor of THE LANCET.

SIR,—I have recently had the honour to receive from Professor Pacini, of Florence, a letter of which I enclose a copy, together with a literal translation which I have made, omitting only the complimentary Italian superlatives. I do not doubt that you, Sir, and your readers will feel an interest in the verdict of this eminent Italian professor with regard to the relative claims of Harvey and of Cesalpino to be considered the discoverer of the circulation of the blood.

I am, Sir, yours, &c.,

Savile-row, October 7th, 1882.

GEORGE JOHNSON.

[COPY.]

Illus. Sig. Prof. Johnson,—Ho letta con grandissimo piacere la sua bella Dissertazione (Harveian Oration) che ella si è compiaciuta mandarmi, circa la grande scoperta della circolazione del sangue; e dietro questa lettura ho dovuto riconoscere che la gloria di avere dimostrata questa scoperta con ogni sorte di argomenti e di fatti appartiene incontestabilmente ad Harvey. Ello però non deve meravigliare e che attualmente i più rumorosi sapienti Italiani preteudono attribuirlo a Cesalpino. Che se Cesalpino ed Harvey fossero tuttora viventi, è certo che i nostri sapienti si farebbero un dovere di attribuirlo ad Harvey. Ma essendo ambedue morti, è naturale che i sapienti Italiani pretendono rivendicarla per Cesalpino: ed ecco perchè l'Italia è detta ancora *la Terra de' Morti*. In prova di ciò potrei citare più di un esempio, in cui non sempre si è lasciata parlare la verità dei fatti; come si è visto ancora ultimamente nella R. Accademia Lincei, quando questa Accademia ebbe a giudicare il famoso concorso per Scienze Biologiche nella seduta solenne del 18 Dicembre, 1881. Pubblicherei pure questa lettera se vuole, purché sia pubblicata tutta intera; e intanto profitto di questa occasione per mandarle, con i miei ringraziamenti alcuni miei opuscoli; mentre mi confermo con tutto il rispetto.

Suo affet. collega,

FILIPPO PACINI.

Firenze, 28 Settembre, 1882.

Translation.

To Prof. Johnson,—I have read with the greatest pleasure your beautiful dissertation (Harveian Oration) respecting the great discovery of the circulation of the blood, which you have been pleased to send me; and having read it I am bound to acknowledge that the glory of having demonstrated that discovery by every kind of argument and of fact belongs unquestionably to Harvey. You ought not, however, to wonder that actually the most clamorous of the scientific Italians endeavour to attribute the discovery to Cesalpino. If Cesalpino and Harvey were now living it is certain that our scientists would consider it a duty to attribute it to Harvey; but both being dead, it is natural that Italian scientists should attempt to claim it for Cesalpino, and thus it is that Italy is still called *the Land of the Dead*. In proof of this I could cite more than one instance in which to speak the truth with regard to facts has not always been permitted, as was seen recently in the Royal Academy of the Lynxes, when this Academy had to decide the famous competition in *biological sciences* at the solemn sitting of December 18th, 1881. You may, if you please, publish this letter, provided that it be published quite entire. Meanwhile I avail myself of this opportunity to send you, with my thanks, some of my pamphlets, and I remain with all respect,

Your affectionate colleague,

Florence, Sept. 28th, 1882.

FILIPPO PACINI.

UNIVERSITY OF ABERDEEN.—The University Court on Oct. 6th appointed the following six extra-professional examiners in medicine—viz., Dr. James Anderson, London. Dr. John Barolay, Banff, Dr. George M. Edmond, Stonehaven, Dr. James Greig Smith, Clifton, Mr. Fred. Treves, London, and Dr. R. M. Wilson, Old Deer.

# THE LANCET.

LONDON: SATURDAY, OCTOBER 14, 1882.

BEFORE leaving the subject of the Inequality of Medical and Surgical Examinations and passing on to that of the Inefficiency of the General Medical Council, it is but right to look at the Scotch view of this branch of the evidence adduced before the Royal Commission on Medical Acts. This is to be gathered from the opinions expressed by the Scottish witnesses—notably by Professor SPENCE, Dr. SCOTT ORR, Dr. HALDANE, Professor GAIRDNER, and Professor STRUTHERS. We publish to-day another part of the evidence of Dr. HALDANE, which tends to show the weak parts of other examinations than those of the Scotch corporations. These investigations into our examining system must be complete and impartial. Nobody can pretend that in any division of the kingdom this system is perfect. If that of the Scotch corporations is most spoken against, it is only fair to admit that, until recently, that of the English College of Surgeons covered a very incomplete number of subjects, and that it is still very uncertain and one-sided. Our own determination is to be impartial, and to be satisfied with no reform that does not give every conceivable guarantee of equality in corresponding examinations in each division of the kingdom. Dr. HALDANE tells us that of 191 candidates for the single qualification of the Edinburgh College of Physicians, 100 were members of the English College of Surgeons, and that of these 22 had to be rejected in the final examination, including medicine, materia medica, midwifery, and medical jurisprudence. Dr. HALDANE takes this as a proof that the examination in the subject of medicine of the Edinburgh College of Physicians is a more severe one than that of the English College of Surgeons. This is not saying very much for it. The examination of the English College is one essentially in three subjects—anatomy, physiology, and surgery. Until lately, neither medicine nor midwifery was at all adequately recognised. It is no proof of the adequacy of an examination of a College of Physicians that it rejects candidates who have obtained a surgical diploma. We accept Dr. HALDANE'S statements gratefully, as a proof of the defects of the examination in Lincoln's-inn, although they do not acquit the Scotch corporations, or explain why members of the London College of Surgeons should seek the licence, not of a London but an Edinburgh College of Physicians. Be this as it may, is there anything in the evidence of the Scotch witnesses to refute the statements of such men as PAGET, GAMGEE, HEATH, STOKER, and JACOB, &c., that men failing to pass the examinations in England and Ireland go with confidence to Scotland and succeed? Let us notice the principal replies of the Scotch witnesses, whose character could not well be higher. Professor SPENCE asked for proof, and said that he did not know of anything of the kind taking place. What more proof can be expected? It is not likely that names of individuals will be published. We confess to feeling that

a gentleman who does not know of "anything of the kind taking place" must lay himself open to the charge of not having taken much trouble to make himself acquainted with facts. Surely all this conviction of English and Irish witnesses cannot be a matter of pure prejudice. We have too much respect for the memory of Mr. SPENCE to dwell further on an entirely inadequate refutation of contrary and positive evidence. We note with satisfaction his emphatic concurrence in the principle "that the curricula and the examinations should be *equal*." Dr. SCOTT ORR had two answers. When pressed with the case of a person alleged to have failed to pass the examination for the Membership of the English College of Surgeons, and then of the Edinburgh College, and who, having shortly thereafter succeeded in passing the examination for the licence of the Glasgow Faculty, was yet, a little while later, to be found an actual *Fellow* of the Edinburgh College, he admitted this might have been the case. His defence is that the same thing *might* have happened reversely. When Dr. SCOTT ORR produces such a case, beginning in rejection at the lowest examinations of Scotland, and ending in the *Fellowship* of the English College of Surgeons, he will have answered the charge; but he has not done so yet. Dr. ORR'S other point is, that if examinations are pitched too high, men cannot be got for country practice. Is it, then, the function of the Faculty and other Scottish corporations to provide men for the country as distinguished from the town? Surely this defence will not be accepted by the holders of the licence of the Faculty. We venture, in the name of country practitioners, to repudiate such an argument as—unintentionally, we are sure, on Dr. SCOTT ORR'S part—an unwarranted reflection on them. Professor GAIRDNER admits "the licensing bodies have been *weak*," but thinks there has been exaggeration. Dr. STRUTHERS, too, uses the doctrine of *asthenia*. There have been "weak points" in the corporations, and he adds: "I do not think my friends in the Edinburgh Corporations have latterly acted judiciously." These are important admissions by men with such associations with the Edinburgh Corporations as GAIRDNER and STRUTHERS. Dr. STRUTHERS thinks, however, that there are only two faults to be remedied: the first is, that one corporation accepts the examinations of another; the second, that Conjoint Boards do not exist except in Scotland. This is a strange way of refuting the charge that in Scotland, where the Conjoint Board does exist, the gate of entrance is wider than it should be, and than it is elsewhere. We cannot but regret that the representatives of Scottish universities, whose privileges and rights have been amply respected in the Report of the Commissioners, should take so inadequate a view of this question, and should feel themselves called on to defend a system which is unfair to the holders of Scotch diplomas, and seems likely to bring these diplomas into serious discredit. It would surely be more kind to the Scotch Corporations to advise them to accept, even to demand, legislation which would free them from the charge of passing the rejected of other boards—a charge of which we can find no disproof in the evidence of the Scotch witnesses.

PERHAPS there is no function of the body which plays a more important part in various morbid conditions of the abdominal viscera than the movements of the bowel; and

certainly there is none which, in its pathological relations, has received less experimental study. Uncertain inference from clinical symptoms is almost all that physicians have had to depend upon in their diagnosis, and in their endeavour to alter by treatment that which they assume to be present. As an instance, we may adduce the difference of opinion which has existed and still exists among distinguished authorities on the question whether there ever is, in morbid states of the bowels, what has been misnamed an antiperistaltic action—a question of great importance in many acute disorders.

Thanks to the well-directed energy of NOTHNAGEL, and so far as animals can furnish it, we have now some definite knowledge. He has made a series of experiments to ascertain by actual observation what modifications the intestinal movements undergo in morbid states. The experiments (described in the *Deutsche Zeitschrift f. Klin. Med.*) involved no suffering to the animals concerned. All were kept insensible by ether—dogs and cats by inhalation, rabbits by subcutaneous injection; and all were killed by division of the medulla oblongata as soon as the experiment was over, and before the return of consciousness. The method employed was that of SANDERS and VAN BRAAM HOUCKGEEST, of keeping the animal, with abdomen opened, immersed, with the exception of the head, in a one-half per cent. saline solution, at a uniform temperature of 100° 2' F. Under these circumstances, as the originators of the method pointed out, rest is the rule in most parts of the bowel, with the exception of the duodenum. Now and then, at rare intervals, there is a gentle peristaltic movement in the small intestine, and local irritation causes only a local effect, without producing any trace of general peristalsis. But the condition is changed at once by the presence of a quantity of gas and liquid distending part of the bowel. This is immediately moved forwards by a stormy peristalsis, a circular contraction behind it pushing the distended portion onwards to the cæcum. Sometimes, however, the movement suddenly stops, to go on again after a brief pause. It is distinctly analogous to the sudden temporary cessation of griping pain, which is familiar to most people. NOTHNAGEL can discover no cause for it, except a sudden inhibitory nervous influence, which its aspect indeed suggests.

As regards the first fundamental question—the occurrence of antiperistalsis—NOTHNAGEL entirely corroborates the statement of ENGELMANN, that the intestinal contractions may take place either upwards or downwards. But the last-named observer, experimenting with the intestine exposed to the air, was in error in assuming that peristaltic action, upwards or downwards, was set up by any local irritant. When the bowel is preserved from the air by the saline solution, local irritation causes a local constriction, if the bowel was previously at rest. Moreover, NOTHNAGEL concludes, from a series of sixty observations, that antiperistalsis never occurs in the normal uninjured intestine so long as no pathological influences are brought to bear upon it.

The effect of injections into the rectum was next investigated, the injections being of indifferent or irritating liquid, tinted with carmine so as to show how far it was sent up the intestine, and post-mortem examination subsequently showed whether it had been carried higher by any movement of the intestine itself. A small quantity of warm

water (from two to five cubic centimetres) had no effect; it remained in the rectum until ejected by a contraction, or until it was absorbed. A somewhat larger quantity distended the rectum, but seemed to excite little peristaltic action, some of it escaping in consequence apparently of the elasticity of the bowel. Iced water caused constriction, which passed a short distance upwards so as to move the injected fluid up from five to twenty centimetres. Olive oil gave a similar result. Of greater significance, however, was the effect of a strong solution of chloride of sodium. A small quantity, three to five cubic centimetres, passed up, by the force of the injection, about ten centimetres. In a few minutes, however, the coloured liquid was carried upwards by a distinct ascending contraction, and the antiperistalsis gradually carried it, together with a mass of fæces, as high as the cæcum. Sometimes the antiperistalsis took the form of a series of circular constrictions, especially marked at the highest part of the column of liquid. Besides this, descending contractions occurred in the lowest part of the rectum. Similar results were obtained with injections of concentrated solutions of nitrate of potash and bromide of potassium, and weak solutions of sulphate of copper.

NOTHNAGEL found that the needle of a hypodermic syringe could be passed through the wall of the small intestine without exciting local contraction, and the minute wound immediately closed without allowing the escape of the intestinal contents. Injections of chloride of sodium were found invariably to cause contractions which passed upwards as well as downwards. In a case of ileus in the human subject he found that chloride of sodium solution has evidently the same effect as in animals, since a small coloured injection into the rectum was found after death to have passed upwards some distance above the cæcum. The fact may possibly prove of great practical importance in the treatment of intestinal obstruction. The injection of indifferent fluids of the temperature of the body had as little effect on the small intestine as on the rectum. The conclusion from this series of experiments is that when the intestine is under normal conditions, or contains only un-irritating contents, the peristaltic contractions occur only in the direction from the stomach towards the anus. If, on the other hand, the contents of the bowel consist of an irritant substance, the stimulant causes contractions to pass also in the opposite direction. Nevertheless it was found that the latter only occurs when the irritant substance is introduced into the bowel in, so to speak, an unphysiological way. A solution of sulphate of copper was injected into the stomach, and quickly passed into the bowel, but, entering it thus, it caused only descending peristaltic contractions. Hence we must assume that, so to speak, preformed arrangements exist, of an anatomical or physiological nature, which determine the direction of the movement.

How does fecal vomiting occur in cases of obstruction of the bowels? It will be remembered that many authorities, from the time of VAN SWIETEN, have asserted that it does not necessarily occur by antiperistaltic contractions. VAN SWIETEN maintained that it was by the action of the diaphragm and abdominal muscles, and BRINTON urged with great ability that its mechanism must be a reflex current in the centre of the distended intestine, opposed in its direction to that of the peristaltic action. VAN BRAAM HOUCKGEEST,

and LICHTENSTERN have experimented on the subject, and were unable to discern any ascending contractions. NOTHNAGEL has made a large number of experiments on this subject. Ligature of the small intestine caused in some cases very little effect. The intestine above gradually became filled without any marked contractions, and the portion below gradually became emptied. In other cases, however, a series of vigorous contractions passed down from the stomach, and distended the part immediately above the ligature, ceasing in the distended portion, and as this extended upwards higher, the section in which the peristaltic contractions occurred became smaller and smaller, until it was reduced to a narrow segment near the pylorus. After the distension had existed for half an hour, local contractions could no longer be excited by mechanical stimulation; the intestine was evidently paralysed. In these cases there was no antiperistaltic action. In others, however, the descending contractions on reaching the ligature seemed to return up the bowel for a very short distance, and were even augmented in force just above the ligature, so that the intestine here was emptier than it was higher up. There was no regular antiperistaltic action, and after a short time these "rebounding contractions" ceased, and the distension and paralysis went on as just described. Sometimes, however, the peristaltic action quickly ceased, but the distended bowel seemed to undergo a slow imperceptible contraction, which caused its contents to pass upwards, because the ligature prevented them from passing downwards. In a series of experiments in which the intestine was ligatured through a small opening in the abdominal wall, and was returned into the cavity for some hours before the abdomen was opened, the events were found to be essentially the same. Various injections were also made into the intestine above the ligature. When indifferent liquids were injected, these were moved upwards, sometimes as much as thirty centimetres, although only by the descending peristalsis and the rebounding contractions already described as occurring just above the ligature. Injections of a concentrated saline solution, however, produced distinct ascending antiperistaltic waves, precisely similar to those produced in the unligatured bowel by the same injection, and by them the liquid was quickly moved upwards.

The paralyzing effect of the distension of the bowel above the ligature, which quickly annihilates its movements, throws an instructive light on the well-known injurious effect of purgatives in cases of intestinal obstruction. As they increase the peristaltic contractions, they carry the contents of the intestine more rapidly to the neighbourhood of the obstruction, and so more quickly bring about the paralysis which follows distension.

The results of these experiments are certainly opposed to the idea that fæcal vomiting is the effect of any regular antiperistaltic contractions. These were only observed as the effect of the presence of irritant substances in the bowel, and the only condition in man to which this observation can fairly be applied is that in which irritating aperients, such as croton oil or colocynth, have been given. The simple diffusion of liquid contents causes their slow extension upwards, and a still greater effect is produced by the rebounding contractions, but the influence of both these was too slight to allow them to be regarded as the cause of fæcal vomiting.

The conclusion of NOTHNAGEL therefore is that this symptom results indirectly by the mechanism which VAN SWIETEN rightly assumed. To some very instructive observations of NOTHNAGEL on the movements of the intestines in other morbid states, we must return on another occasion.

ALL error has truth for its starting-point, and underlying the wildest flight of fancy there is to be found a solid substratum of fact. The philosophy of BERKELEY, antithetical as it is to the prevailing belief in matter as the sole embodiment and source of force, has so much truth in it that only the narrow-minded or unreflecting can wholly reject or disregard it. To the intelligent student of the so-called "medical sciences," and to the practising physician, Berkeleyism supplies the only key that will unlock a world of mystery, and the only guiding principle in the interpretation of a multitude of obvious but unsafe inferences. Translated into the language and terminology of contemporary schoolmen, the essential principle of this system of philosophy may be said to consist in the recognition that the external—as it stands related to our consciousness, whether through the mental or the physical senses—is the reflection of our own conceptions. What we see, hear, smell, taste, and touch are not—so far as we are concerned—the things themselves, but our sensory notions or impressions of them.

Between us, the internal; and the objects that surround us, the external, the very existence of which BERKELEY first doubted, then denied, there intervenes a halo or cloud—the personal environment through which all impressions are transmitted and have to be received; and by which every impression is modified, so that when it reaches the mind, and becomes a conception, it only more or less faithfully represents the external, but is never its true counterpart. This is what happens to that which comes to us through our environment. On the other hand, what leaves us is, so to say, projected upon the mirror-like inner surface of the mental and sensory medium that surrounds us; and just as every pane of window-glass plays two parts in relation to light and its pictures, transmitting and reflecting, so that we see through it, and at the same instant see our own reflection on its surface, so in looking at the external through our environment, we see surrounding objects—albeit distorted by our medium—and at the same moment see our own ideas of fact superimposed upon the external and mingling with it in such fashion that it is difficult, sometimes impossible, to distinguish between the true external and the projected imagery of our own mind-chambers.

There is something more in this than merely "seeing things through our own spectacles," as the phrase goes, because what we see is, in part at least, not an object but a reflection of self contributed by our "environment." The existence of such a halo or enveloping cloud of consciousness as we have termed the "personal environment"—in a special sense,—cannot be doubted as a subjective experience, although some may be inclined to reject it as a scientific proposition. The personal environment—call it what we may—of the child is blank, and yet it strangely distorts his vision of the external. As time rolls on and his education by surroundings is advanced,

the horizon of his perception extends, and his strength of view becomes greater, but the projections of his own thought and fancy multiply, and these stand pictured on the medium through which he looks at the external, so that the life of relation is really a life of experience, and experience is always a thing of self, and determined by the way things affect us rather than what they are in themselves.

It follows that, in a very real and practical sense, for ourselves and others, both subjectively and objectively, we need to analyse every impression or description of an impression, with a view to distinguish between the actual and the imaginary. This is not an easy, and it will often prove a very onerous, duty to discharge, but it is one which must be performed at any pains or cost, if we would avoid being deceived and deceiving others. In the study, in the consulting-room, at the bedside, in the laboratory, or in the post-mortem room, in scientific investigation, and in practice, it is indispensable to be severely scrutinising and to keep the inevitable, and in a way natural, mingling of the real and the unreal always in mind, if we would be accurate. It follows also that what we have called the "personal environment" is the source and field of impressions and visions which are ideal although they seem actual. Failure to recognise this fact makes otherwise intelligent and truth-loving minds the victims of self-deception in the matter of many of the occult phenomena—for example, those of spiritism, mesmerism, hypnotism, metallo-therapy, and the host of half-truths distorted and transmuted to errors by the intervening influence of the environment with its mental reflections and sensori-motor reflexes.

It is absurd to suppose, and vexatiously wanton to assume, or try to prove, that all the believers in these "isms," which have done, and are still doing, much to retard the progress of rational science, intentionally deceive either themselves or others. They are simply persons who, from the habit of their intellectual and mental work—using the latter term in its broadest sense—do not recognise the existence, and therefore make no allowance for the influence, of the enshrouding medium which interposes between every consciousness and the external. Ghosts, spirits, waking dreams, dozing dreams, sleeping dreams, and any and all of the objecto-subjective phenomena of consciousness, whether in health or disease, may be real—as real as anything can be—to those by whom they are witnessed or experienced.

The student or practitioner who does not perceive and—which is more to the point—bear constantly in recollection these facts about mental reflection can never be quite safe as regards his own impressions and the use he makes of descriptions of impressions; nor can he be a perfectly trustworthy reporter of experiences and observations for the information and guidance of those with whom he is associated. It is always timely to raise a warning cry in presence of the peril of errors growing out of truths; but it is especially reasonable to call attention to the subject at the commencement of a new session of study and clinical work, in the course of which we are sure to be treated to the narration of divers marvels. It would be well if we could incorporate a spice of Berkeleyism with the crude materialism of what is now deemed rational medicine.

THE Royal Victoria Hospital, the great invaliding hospital of the British Army, was established shortly after the termination of the Crimean War with a view to supply a want which was greatly felt, of a hospital for the reception of the sick and wounded during war, and of men sent home as invalids at all times. The accommodation provided at Fort Pitt, the previous invaliding hospital, was found to be quite inadequate to the requirements of the army, and its situation in the midst of a large garrison like Chatham was attended with many serious drawbacks. After much consideration and a good deal of opposition, the situation where Netley Hospital now stands was selected, and the present building erected to accommodate about 1000 invalids, and also to provide a training school for army medical officers, where, on entering the service, they might be taught those special subjects bearing upon the health of troops serving abroad, and the duties—surgical and sanitary—devolving upon them when employed with an army in the field. The importance of such an institution can only be appreciated by those who have had an opportunity of watching its working. The careful treatment of sick and wounded by the experienced officers composing the staff, and the valuable instruction received by the junior officers and the surgeons just commencing their career in the army, fully justify the expectations which were formed by those to whom the establishment owed its origin. A few years ago the discharge depot for time expired men was removed from Chichester to Netley, and the anomaly was created of an establishment of unemployed idle soldiers within the walls of a hospital intended only for the care of the sick. Happily this has now been abolished, and the building is again employed solely for its original purpose. On the outbreak of the recent war every preparation was made for the reception of the wounded and sick who might be sent to England from Egypt. Quarters were fitted up in the hospital for the reception of twenty-five officers, and, by the removal of the time-expired depot, accommodation was provided for 978 men. When a vessel containing invalids or wounded arrives at Portsmouth a special train for Netley is provided, and an intimation sent by telegraph of the probable time at which it will arrive, and the number of men it will convey. An ambulance and stretcher party, proportioned to the numbers intimated as coming, is in attendance at the Netley station on the arrival of the train, and the patients are removed expeditiously and comfortably to the hospital, under the superintendence of the principal medical officer assisted by the medical staff and the officers of the Army Hospital Corps. On arriving at the hospital they are immediately told off to their respective wards, where beds are ready for those who require them, and where they at once receive such nourishment and attention as may be deemed necessary for them. There have already been thirteen officers and 839 men admitted from Egypt. Upwards of half the former and above one-third of the latter have been cases of wounds, and the remainder medical cases, consisting chiefly of dysentery, sunstroke, and debility from the hardships undergone in the field and from climate, and there have also been several cases of typhoid fever among them. Of the surgical cases many have been severe gunshot wounds, which, however, under the judicious and careful treatment of Professor LONGMORE, have as yet done well. We are informed that in the treatment of these cases Listerism

is carried out in its most minute details. We regret to learn that when the discharge depôt was removed from Netley, the military staff was not removed with it, but the Commandant and Assistant-Commandant were left, with apparently nothing to do. The system of dual government by a military commandant and a medical chief in a hospital cannot fail, like all dual governments, to prove injurious to the best interests of the sick, and subversive of the efficient and harmonious working of the establishment—a point of immense importance to the patients; but we understand it has been decided that the dual government is to cease.

## Annotations.

"Ne quid nimis."

### THE VACANT EXAMINERSHIP AT THE ROYAL COLLEGE OF SURGEONS.

ON Thursday next the Council of the Royal College of Surgeons will elect a member of the Court of Examiners to fill the vacancy caused by the resignation of Mr. Birkett. This gentleman, who has occupied a seat in the Court since the year 1872, will not seek re-election. Four actual or probable candidates are already spoken of—namely, in order of seniority as Fellows of the College: Mr. Thomas Bryant, of Guy's (1853); Mr. George Lawson, of Middlesex (1857); Mr. Christopher Heath, of University College (1860); and Sir William MacCormac, of St. Thomas's (1871). Mr. Bryant and Mr. Heath, like all the existing members of the Court of Examiners, are members of the Council. Whether this fact will in any degree lessen their otherwise strong claims will depend on the view which the majority of the Council may take as to the expediency of selecting, as far as practicable, examiners from among the Fellows who are not members of the Council. There is much to be said in favour, not only of keeping the Court of Examiners more or less independent of the Council, but also, on the other hand, of obviating a preponderance of examiners in the Council. It has happened more than once within the last twelve months that the examiners have, by dint of numbers, forced measures upon the Council that were opposed by a respectable minority of independent members. As there are ten members of the Court of Examiners and only twenty-four members of the Council, it is never difficult for the examiners, by combination, to gain a victory in the Council, even against a strong opposition. This is obviously undesirable, though not altogether avoidable. Those Fellows who are most likely to make good examiners are sure, sooner or later, to find their way into the Council; and it would be eminently unwise to push the principle of independence and separation so far as always to refuse to elect a candidate to the Court of Examiners because he was already in the Council. In the present instance, however, the principle may be carried out without any disparagement of the undeniable merits of either Mr. Bryant or Mr. Heath. Mr. George Lawson has for many years been successfully engaged as a teacher and lecturer on surgery at Middlesex Hospital, and has had considerable experience as an examiner in surgery at the Royal College of Physicians. Sir William MacCormac is so junior a Fellow that his candidature may be taken rather as a forecast of his future expectations than a declaration of his immediate intentions.

### A CHARGE OF MANSLAUGHTER AGAINST A MEDICAL MAN.

CONSIDERABLE interest has been excited by a charge of homicide by imprudence, preferred against Dr. J. D. M. Coghill of Colombo, in having caused the death of Mr. Stephen Rowan Aitken, by negligently and without due caution prescribing and causing to be administered certain medicines. From the evidence, it would appear that Mr. Aitken, who was thirty years of age, had been under Dr. Coghill's treatment for tapeworm for nearly three months. A number of remedies had been prescribed, and had failed to bring away the head of the worm, although they had given rise to considerable intestinal disturbance and irritation. For nearly two months no joints were passed, and it was hoped that the treatment had proved successful. Some eight or ten days before his death Mr. Aitken called on Dr. Coghill, told him he was again troubled by his old enemy, and begged that something more might be done towards effecting a cure. He said he would begin taking medicine on the following Sunday morning. He was given a prescription, of which the following is a copy:—"R Ext. æth. filic. mas., 1½ oz.; pulv. kamalæ, 3 drachms; pulv. granati rad., 3 drachms; mucil. acac., syrup simp., q.s.; aq. cinnam. ad 4 oz. Half to be taken at bedtime, and half at 2 A.M." The chemist having no powdered pomegranate root in stock, communicated with Dr. Coghill, and the prescription was made up without it. It appears that he noticed the large dose of male fern, but thought it might be dispensed with safety. About 11 o'clock on Sunday morning Mr. Aitken wrote to Dr. Coghill saying that he had taken the first half of the draught, and that it had caused him a good deal of distress, but he had passed nothing but a few joints. He wanted to know if he might take the other half, and an answer was returned that he might do so. A little later he sent again, saying that he wished to see Dr. Coghill at once. He was seen at two o'clock, when it was found that he had been purged and had vomited a good deal, but had not been able to eat anything. He had passed a large quantity of the worm, which he had placed in a finger-glass in spirit. He was ordered chicken-broth and beef-tea and brandy, to be taken frequently in small quantities, and directions were given that he should be kept warm. He was seen again between 7 and 8 o'clock the same evening, and was then not so well. He had been again purged and had vomited, and was complaining of cramps in the hands and toes. He had some champagne, and a large mustard poultice was applied to the pit of the stomach, with hot-water bottles to the feet. He seemed soothed, and said he should be better if he could get some sleep, but the pain in the stomach kept him awake. He was given a hypodermic injection of a quarter of a grain of morphia, which afforded him speedy relief. He fell asleep, and directions were given that he should be awakened in two hours for some more chicken-broth and brandy, and that this should be repeated at intervals during the night. From the statement of the friends it appears that at a quarter to twelve he was bathed in perspiration and was very drowsy, but with much difficulty he was made to swallow a cupful of chicken-broth. About half-past one Dr. Coghill was sent for hurriedly, and on his arrival found the patient dead. He gave a certificate that he died of "choleraic diarrhœa," and expressed an opinion that it was induced chiefly by the weather, although it was possible that the irritation resulting from the treatment had rendered him predisposed to such an attack. The pupils after death were widely dilated, and this was accepted as evidence that the morphia could not have exerted any injurious effect.

The post-mortem examination was made by Dr. Carbery, who found general venous congestion of all the organs, including brain, heart, and lungs. The right side of the heart

was filled with blood partially clotted, the left side being empty. The stomach was empty, and at the cardiac end there was a congested patch, about three inches in diameter, covered with small lines of extravasated blood. The outer surface of the small intestine was of a rose-red colour, and the mucous membrane was marked with patches of congestion, with slight extravasation, particularly in the first three feet. Other patches of minute extravasation were scattered through the intestine. The mucous membranes of the stomach and intestines were smeared with a dark-brown fluid having a smell of ether. Curiously enough, there was only one kidney, the right, which was about twice the normal size.

Several medical witnesses were examined, and they were unanimously of opinion that the dose of male fern administered was poisonous. Dr. Coghill, on the other hand, according to the report upon which we are dependent for the facts of the case, said that he had previously given six drachms without ill effect, and maintained that the dose was not excessive, giving as his authority for the treatment Dr. William Brinton, of London, as quoted in the last edition of "Napheys' Modern Medical Therapeutics." The explanation was considered satisfactory, and the accused was discharged, the verdict at the inquest being that "deceased died from exhaustion produced by irritants considered necessary for the treatment of his case."

The case, as we have said, presents many points of interest. The use of the rhizome of ferns as a vermifuge was well known to the ancients, and is referred to by Theophrastus, Dioscorides, and Pliny. It was also administered during the Middle Ages and had a place in German pharmaceutical tariffs of the sixteenth century, as well as in Schröder's Dispensatory. It is the active ingredient of most quack remedies for tapeworm. Peshier of Geneva was the first to employ the ethereal extract as a substitute for the bulky powder of the root, but it was not till about 1851 that it was generally employed in this country. The ordinary dose of the preparation is a drachm, and we find no record of its having been previously administered in the heroic doses recommended by Dr. Coghill. The prescription as given in Napheys' Therapeutics is clearly a mistake, the word *ounce* having been substituted for *drachm*. The original prescription was not by Dr. William Brinton at all, but occurs in a paper by Dr. John Brunton, published in the *Glasgow Medical Journal* in 1865, the dose being one and a half drachms, not ounces. Had his directions been followed no harm would have ensued. It is no easy matter to apportion the blame in this unfortunate case. A grave responsibility undoubtedly rests with the editor of the work in question, and immediate steps should be taken to notify the occurrence of this lamentable error. At the same time it is difficult to understand how a medical man could blindly copy a prescription from a book without first ascertaining the correctness of the dose.

#### THE INCREASING COST OF LUNATIC ASYLUMS.

It is unreasonable to complain of the increased cost of maintaining asylums for lunatics, and of feeding and clothing their inmates. The spirit of the times has tended, and is still tending, to the multiplication of comforts in asylum life. What were deemed luxuries ten years ago are now classed as necessities. If Mr. Hibbert had taken the trouble to recognise the rise in prices generally, and to estimate the additions made to the appliances of asylum life within recent years, he would not have expressed surprise on finding a large increase *pro rata* in the decade 1871-81. The only wonder is, that the increase is not greater, even making very little allowance for the increment of the population as a whole and, of course, of the insane in proportion.

#### NOTIFICATION OF DISEASE IN LIVERPOOL.

THE Health Committee of Liverpool have received a deputation of medical gentlemen on the subject of the notification of disease. The chief speaker was Mr. Carter, who made some statements which were most satisfactory, and others which do not seem to us so happy. Mr. Carter said that they were as anxious as the Committee for the public health, and that they had no sentimental objection to notification. Their objections were entirely based on experience. The experience he referred to was twofold, and to this effect: that in the places where notification was in force there was a concealment of disease on the part of the poor in the first place, and a friction between the profession and the sanitary authorities in the second. There is something in these arguments, but not so much as our friends in Liverpool think. There is sure to be at first some evasion of a law so new, and in its naked form so inconvenient; and until medical officers of health learn to consider their brethren in practice a little more, there will be occasional friction. But these will become less and disappear under the educating influence of a good system of notification by the householder, who will not be required to notify until the medical attendant is fully satisfied of the existence and nature of an infectious case. Mr. Carter was entirely right in calling for a Parliamentary discussion of this question, and demanding that it should be dealt with in a general law. It is intolerable and unworthy of Parliament that it should be dealt with furtively in local Bills, often ostensibly introduced for other purposes. We cannot compliment Mr. Carter on his last argument: that, in the event of compulsory notification, medical men will be induced, from humanitarian feelings, to give inexact certificates. This argument was illustrated by the statement that, though drinking kills from 40,000 to 50,000 persons annually, only 600 deaths are attributed to it by the Registrar-General. This is not much to the point, and is not very complimentary to the profession. Medical men return a drunkard as dying of disease of the liver or kidney, or what not. This is the cause of death. The cause of the disease is another question, on which the State has not asked medical men to be explicit in their certificates. The compulsory notification by parents of the nature of a disease that is dangerous to others is a very different thing from the publication of an opinion as to the cause of a disease that is only dangerous to the person affected. Besides, there is no shame in having an infectious disease, such as there is in having delirium tremens or alcoholic cirrhosis.

#### RAPID BLANCHING OF THE HAIR IN NEURALGIA.

IN the *Revue de Médecine* (September) Dr. Raymond records a case which must be added to the list of others more or less well authenticated, where the curious phenomenon of the sudden blanching of the hair has taken place under the influence of profound nervous disturbance. He prefixes to his record the *ex cathedra* statement of Kaposi in Hebra's treatise, who relegated all such reported instances to the region of fable, owing to the impossibility of accounting for such decolouration on physiological grounds. However inexplicable, such facts as Dr. Raymond's cannot be gainsaid. The case in question was that of a lady whose hair was abundant, and of a black colour. Although emotional and nervous, she had never been attacked with hysteria, and enjoyed good health until July, 1881, when she began to suffer from insomnia, only relieved after sea-bathing at Arcachon. In January she was again much affected by a considerable monetary loss, became restless and sleepless, and lost her appetite, and about the same time began to suffer from neuralgia. The catamenial flow was arrested at the time of the mental shock, and had not recurred. She was seen by Dr. Raymond on the 27th January, when she complained

of great weakness and of pains in the head, abdomen, shoulders, and legs. Nothing abnormal was observed in these regions. The pain was not only continuous, but was marked by frequent and violent exacerbations. Spots of tenderness were detected in many parts of the face and head, as well as over the shoulders, the first and second dorsal spines, and on the arms and legs. There was also tenderness in the ovarian region and in the abdomen. Quinine, then aconitine, and on the 31st bromide of potassium were prescribed in succession without relief. At half-past nine in the evening of the 31st the pains in the head were extremely severe, and morphia had no effect. At 2 A.M. the pains were at their maximum. At this time the hair had its normal colour. At 7 A.M. she was found with her hair nearly completely decolourised. The black colour was preserved only on the sides and back of the head, elsewhere the hairs were of nearly a bright red, a certain number (especially of the smaller hairs) being perfectly white. In some parts there was a considerable admixture of white and red hair. In other parts of the body no change in the colour of the hair had taken place. The pains persisted throughout the day, but ultimately some sleep was obtained by large doses of bromide. In two days' time most of the red hairs had become blanched, and a large quantity fell off. The neuralgia had now abated, and her general health improved, but with almost total loss of hair, a few white, red, and black hairs remaining on March 30th in the temporal and occipital regions. Dr. Raymond remarks that the phenomenon is evidently to be explained by the profound disturbance of innervation produced in the first instance by a severe mental shock, characterised by neuralgia, especially of the scalp, and culminating in the decolourisation of the hair when the neuralgia was at its height.

#### THE BELFAST MEDICAL SCHOOL.

THE Royal Hospital, which undertakes the entire clinical instruction of the students of the Belfast Medical School, has up to the present been without efficient special departments for the treatment of diseases of women and children, and diseases of the eye, ear, and throat. The committee has accordingly proposed to open special departments in these subjects, at which their students can receive proper instruction in these more special forms of disease. But a serious difficulty has presented itself in the form of a want of proper space and funds. This has occasioned a counter proposal, to the effect that the six special hospitals at present existing should be amalgamated with the Royal Hospital for clinical purposes, and thrown open to students. To judge from comments in the lay press this proposition promises to meet with considerable support. There can be no doubt that special departments at general hospitals are far more worthy of support than are separate hospitals for the various special classes of disease. There is a great saving of money in having all under one management; there are great advantages to the patients in attending where they can be thoroughly treated, rather than at a special institution where a single local ailment, often but a part of the real disease, is treated; there is also a saving of time and labour to the students in receiving all their clinical instruction under one roof. The best form of amalgamation of the Belfast hospitals would no doubt be a complete one, in which all should be placed under one common governing body and all the funds entrusted to one treasurer. Failing this, however, an arrangement by which the Belfast medical students can receive instruction at all the hospitals is undoubtedly a wise one, but care should be taken not only to give the privilege, but to insist on the students availing themselves of it; and also to ensure that the instruction at the special hospitals shall be regularly and systematically

given; and for these ends the medical school authorities ought to have representatives on the committees of these special hospitals. We trust that some steps will be taken at once to supply the serious want there appears to exist at present in the Belfast Medical School, and that, at any rate during the present session, the students will receive proper clinical teaching in the important subjects of the diseases of women and children, and of the eye, ear, and throat.

#### LIME-JUICE.

THE question as to the respective merits of lime-juice and lemon-juice as antiscorbutics is frequently brought forward for discussion. Lime-juice is used exclusively in the Royal Navy; lemon-juice almost generally in the service of the mercantile marine. Practically, we should say the antiscorbutic value of the two juices would be the same if both were used freshly expressed from the fruit; but there is no question of the vast superiority of the lime-juice served out to the ships of the Royal Navy over the average specimens of the rival juice found on board the majority of our merchant ships. Why this should be so it is difficult to determine, for we see no reason why lemon-juice should not preserve as well as lime-juice, if equal care were taken with its preparation. Two objections formerly urged against the introduction of lime-juice into the mercantile marine were its expensiveness compared with lemon-juice, and the difficulty of obtaining a regular supply. Both these objections have ceased to exist. The growing favour with which lime-juice has been received by the general public, as an ordinary beverage, has encouraged the cultivation of the fruit to a large extent, so that ample supplies now reach us from Montserrat and the West Indian Islands to meet the increased demands. Whilst considering the rival claims of lime-juice and lemon-juice as antiscorbutics, we must not forget that their employment is to a certain extent a reproach on our carelessness with regard to the dietetic conditions under which our sailors subsist at sea on long voyages, since the use of lime-juice or lemon-juice indicates that the dietary employed on board ship is an artificial one. In spite of the vast improvements that have taken place in naval architecture, and in the comforts and luxuries afforded to passengers in the magnificent ocean hotels that our steamships have become, little change for the better has been experienced by the common sailor; indeed, in many cases, we believe his lot to be far harder than in the days of the roomy sailingship, and before the introduction of lime-juice, when owners relied more on the quality of the provisions to prevent an outbreak of scurvy than at present; now they have this sure agent to hide their shortcomings in respect of the food supplied. There ought, however, to be no difficulty in providing sailors with a daily supply of fresh provisions even on the longest voyages. Fresh meat preserved in tins should not be more difficult of carriage than salted; indeed, if properly managed, it is less so, since the weight and bulk of the added salt are avoided. The question of a constant supply of vegetables is a more difficult one, since their efficiency when dried and preserved is somewhat limited, but this might, we think, be overcome by using vegetables cooked on shore and preserved in tins. At present the supply of vegetable food served out in any form is certainly inadequate considering the ease with which both in the dried or tinned form they can be procured. It is to be hoped that ere long the Legislature will devote some attention to this important point. We are now able to bring to our shores fresh produce in the shape of meat, fish, and fruit from distant regions. It is not unreasonable to insist that our sailors should participate in the benefit thus conferred on our land population, and that the same agencies employed in the preservation of fresh articles

of food during their transit on long sea voyages for use on shore should be available for the sailor as well. It took nearly two hundred years to enforce the fact that lemon- or lime-juice was a preventive of scurvy; we hope a shorter period will elapse before the lesson is learnt that it is possible by an improved dietary to do away with the necessity for the employment of that agent at all.

### A WORD FOR TOBACCO.

IN a pleasantly chatty article, which takes us to Paris, Jules Noriac, Henri Mürger, and *la vie Bohémienne*, the *Daily Telegraph* of Monday last incidentally refers to the views upon tobacco expressed by the late Dr. Anstie. "The effect of tobacco-smoking in moderation," Dr. Anstie writes, "on the majority of persons who are skilled in the use of the pipe is a marked increase of stimulation, the pulse being slightly increased in frequency and notably in force, and the sense of fatigue in body or mind being greatly relieved. This stimulation most assuredly is not followed by depression. On the contrary, the smoker seems lighter and more cheerful, and the pulse maintains its firmness, in many cases for an hour or two, and even then yields to no morbid depression. Where depression is produced, it is produced early, and is a sure sign that even the small dose is too much for the smoker's constitution, and that he had better not smoke at all." It is refreshing to come upon this sensible language in these days. We live in times in which the custom is to denounce as deleterious everything which happens to be pleasant. Man could probably live without tobacco, as he certainly used to live without clothes; but the fact that both these luxuries are in the nature of comforts should not necessarily spur us into antagonism against either of them. And so it is with the question of alcohol. If Anstie's little book, "On the Uses of Wines in Health and Disease," published by Macmillan, were generally read, a great deal of the prejudice existing upon this subject would give place to views which would not be the less sensible because they represented unprejudiced examination of the question from a physiological standpoint, freed from the bias which moral considerations dependent on the weakness of human nature must necessarily introduce.

### FEVER IN THE COUNTRY.

WE have frequently occasion to refer to the dangers undergone by families who spend a month or more during summer in country quarters. A lurking but fatal foe, and one about which, perhaps, they had scarcely cared to inquire, finds a fertile field, and, through one fever or another, the holiday time is changed into a time of mourning, or of grave anxiety. Certain remedies are proposed for this state of matters, and severe measures may be necessary with those who, in letting houses or rooms, purposely conceal the recent existence therein of infectious disease. Yet it is likely that a large part of the evil is due to ignorance and supineness rather than cupidity. In many cases where infectious diseases have become endemic the knowledge of, or even interest in, the laws of health, is simply non-existent in the minds of the lower classes of the population; whereas their only educated advisers on general subjects are either equally ignorant on this matter, or are so anxious to point another moral, that physical causes are completely overlooked, and the epidemic or "visitation" only ends when suitable material for its spread is wanting. What seems needed in rural districts especially is some educational machinery by which the now well-known principles guiding the spread of infectious diseases may be made more quickly to penetrate the mass, that they may no longer stand aside with folded hands while the poisons find their way,

not only by atmospheric pollution, but by a complete soaking of the soil around and consequent contamination of their water supply and sewerage system, into their whole environment. The amount of literature dealing with sanitary matters now falling into the hands of working-class country readers is quite insignificant, while they continue to be so deluged with religious tracts that their distributors are often looked upon as little short of nuisances, and their influence for good diminished to a corresponding extent. Were short and plain statements regarding ordinary hygienic laws as often found in the reticule of the philanthropic lady on her rounds of mercy as is now the ubiquitous tract, we could promise the fair distributors that amount of success which they now fancy so difficult of attainment. That cleanliness is next to godliness is a text which may yet afford material for many quiet remarks, and that cleanliness in the presence of infectious disease can only be attained by the complete destruction of the causative germ, is a lesson which needs wholesome enforcement. In many country districts the surroundings of the people are so deplorable as to render the presence of fever a quite normal state of matters; Providence is looked upon as sole agent in the outbreak, and interference is looked upon as impiety. Health officers and local authorities have done much; but were the evil sufficiently understood we do not doubt that philanthropists would be found ready to do a work similar to that so abundantly undertaken in the cause of temperance, and by missions of various kinds to the poor. We want "Sanitary Societies" of far less pretence than those which meet autumnally, and treat us to such eloquent but frequently futile harangues; societies embracing in their membership large numbers of the people, from among whom would be chosen men and women sufficiently advanced to act as leaders, yet with humility enough to enter the houses of the poor, and to demonstrate there the value of those simple laws which are so often forgotten by the transcendentalists.

### INTERNATIONAL DEBATE ON ALCOHOLISM.

IN the Second Section of the Geneva Sanitary Congress, Dr. A. L. Roulet, Councillor of State of Neuchâtel, urged the necessity of international organisation to obtain more precise data on the effects, direct and indirect, of alcoholism. Similar statistics are required from each country as to the amount and quality of alcohol consumed, the nature of the drinks most popular, and the criminal and medical returns in connexion with drunkenness. Dr. Roulet proposes to collect all the laws of every country affecting the sale of spirits and the repression of drunkenness, and suggests the extension of those measures of propaganda which the Temperance Societies have rendered so familiar in England; but he concludes by asserting that no measure against alcoholism will produce any serious result till some chemical test has been discovered which will enable us to estimate rapidly the quality of alcohol—the proportion of non-ethelic alcohol that a given volume of alcohol may contain. Dr. Roulet would forbid the sale of all but alcohols made from the grape. During the course of the discussion that followed these proposals, it was estimated that in Switzerland 4 per cent. of the deaths, or 1 death per 1000 of the population per annum, could be attributed to alcoholism, and that excess was more general than in France. In the canton of Neuchâtel the proportion is 11 per 1000. The consumption of alcohol per head of the population was estimated at 23 litres in Denmark, 16 litres in Russia, 10 litres in Sweden and Germany, 9 litres in Belgium, about 7½ litres in Switzerland and the United States of America, 6 litres in England, 4 litres in Austria, and 3 litres in France. In the southern countries, such as Spain and Italy, the proportion was much less. M. E. Agave proposed as a remedy that the

State should control the manufacture and sale of alcohol, as it had done the sale &c. of tobacco in France; while Dr. de Thérésiopolis, of Brazil, insisted that coffee was the natural antidote to alcohol, and its consumption as a nutritive stimulant should be widely encouraged. The bad, indeed the dangerous, character of the water-supply in many European towns also helped to stimulate inebriety. In Brazil, he maintained, the people had better water, drunk more coffee, and were more sober. The idea of a State monopoly met with considerable opposition. Dr. Landowsky insisted that drunkenness was the scourge of Russia, and this was due precisely to the fact that the trade in alcohol was a Government monopoly. In Russia the drunkard was venerated as much as the Arab venerates the madman. Peasants who had not money enough to drink copiously, pretended to be drunk for fear of being qualified as freethinkers, atheists, or nihilists, who are renowned in Russia for their comparative sobriety. Dr. Roulet, in reply, remarked that the State distillery at Berne was very unpopular, and declared he preferred an army of inspectors to an army of Government *employés*. Finally, Dr. Lubesski thought the occasion a good opportunity of challenging the French idiom, "Drunk as a Pole." In defence of his national honour he pointed to the statistics proving that drunkenness was more prevalent in several European countries and various districts of France than in Poland. Altogether the discussion seemed to show that the chemist, by facilitating analysis, would do more to prevent the evil effects of alcoholism than either private temperance societies or public legislation.

#### ANOTHER CHARGE AGAINST GUY'S HOSPITAL.

IN reference to the most recent charge brought against officials of Guy's Hospital, we felt it our duty to make some inquiries at the hospital, where we obtained from the house-surgeon the real facts of the case. It appears that on Friday morning, the 6th instant, half an hour after midnight, a cabman was brought to the hospital by his wife and a friend, who stated that he had fallen in getting out of his cab. The man smelt strongly of spirits, and appeared very drunk indeed, so much so that the house-surgeon gave him an emetic, and, that failing to produce effect, used the stomach-pump, with the result of removing from the stomach a very large quantity of strongly alcoholic fluid. After this operation the patient so far recovered as to be able to give his name and address and to walk out of the hospital to the cab, supported by his friends. He had been carefully examined by the house-surgeon, the house-physician and others being present, and no injury could be discovered beyond a bruise just above the left eye and a graze on the nose. From *The Times* report of the inquest which was subsequently necessary, it appears that the man was so helplessly drunk before the accident occurred, that he had to be driven in his own cab to his master's yard by a friend; on arriving, he tried to leave the cab, and in so doing fell. The diagnosis of the house-surgeon that the man was drunk was therefore abundantly confirmed; this being so, it seemed extraordinary that the coroner omitted to order a post-mortem examination to be made, so that the cause of death might be accurately determined, but was satisfied with the evidence of a medical man who had never seen the patient alive; still more strange that he did not call for the evidence of the hospital officer, especially as charges of gross inhumanity had been made against him and the nurse in the course of the inquiry; these, we are informed, can readily be refuted. It is something more than strange that the coroner, after such evidence, the truth of which remained unsubstantiated, should have felt justified in making "strong remarks," and thus should have led the way to record a formal reprimand against the hospital

officials. We are glad to hear that the matter is not likely to end here; it has of late unfortunately become the fashion to bring sensational and false charges against this hospital, and the authorities are determined that these shall no longer pass unchecked; they have therefore resolved that an effort shall be made to have the present charge fully investigated, and with this intention an application has already been forwarded to the Home Secretary calling his attention to the matter.

#### A CASE OF GASTROSTOMY.

ON Wednesday, the 4th inst., Mr. Francis Mason performed the first step of this operation at St. Thomas's Hospital on a man aged about sixty for rapidly increasing carcinoma of the left tonsil and neighbouring parts. An incision about two inches and a half in length was made parallel with the costal cartilages of the left side and about a finger's breadth from their margin, the lower end of which was about opposite the ninth rib. The structures of the abdominal wall were divided until the peritoneum was reached, which was carefully opened. The forefinger and thumb of the left hand were then introduced, and, guided by the left lobe of the liver, the stomach was readily grasped and brought out slightly at the wound. Great care was taken, both before and after the peritoneal cavity was opened, to arrest all hæmorrhage with catgut ligatures. The parietal layer of the peritoneum was accurately adjusted in contact with the visceral layer of the stomach, and the two surfaces were kept in contact by passing a carbolised silk thread through the whole thickness of the abdominal parietes, and also through the serous and muscular walls of the stomach; four such stitches were employed. Two other deep sutures were made to transfix each end of the wound only, care being taken to include the peritoneum. Lastly, a stitch was passed through the serous and muscular walls of the stomach itself, and was left hanging from the wound to be used as a guide for the future opening of the stomach. Superficial stitches were used to unite the edges of the skin wound. The operation was performed throughout under the carbolic spray, and dressed with the usual antiseptic precautions. The patient was very comfortable during the remainder of the day and passed a good night, but on the following day he complained of hiccup, which distressed him a good deal, giving rise to a painful dragging in the region of the wound. This was allayed by the administration of small doses of medicine containing dilute hydrocyanic acid; beyond this nothing but ice in small quantities, and afterwards, at the patient's special request, a small quantity of tea was allowed by the mouth, he being fed by nutrient enemata. On the second day there was some difficulty of breathing, and he spoke of a sensation of not being able to cough up phlegm and other accumulations from the air-passages. Still his temperature kept fairly normal. On the third day, however, the temperature rose to 101°, and in the afternoon his dyspnoea became so urgent that it was thought necessary to perform tracheotomy as a *dernier ressort*. This operation was performed by Mr. Duncan, the house-surgeon, with some relief, but, in two or three hours after, the patient died, apparently from exhaustion, exactly seventy-two hours after the gastrostomy was performed. At the post-mortem examination, it was found that adhesion of moderate firmness had taken place between the visceral and parietal layers of the peritoneum at the site of the operation, but not sufficiently firm to heal. The mucous surface of the stomach had not been perforated, and there was no general peritonitis. It may be added that the patient inhaled ether during the operation, which may possibly account partly for the dyspnoea, and also that he had some symptoms of carbolic poisoning, as indicated by the condition of the urine during life.

## THE MEDICAL SOCIETY OF LONDON.

THIS Society will, under the presidency of Mr. Francis Mason, open its 110th winter session on Monday evening, the 16th inst., when, after the conclusion of the ordinary routine business and the delivery of a few introductory remarks by the President, Mr. Dolan of Halifax will read the *résumé* of his essay on Whooping-cough, which obtained the Fothergillian Prize of the Society in March last. Much important work is already arranged for the weekly meetings. On the 23rd inst. Mr. Bryant will read a paper on Inflammation and Ulceration of the Tongue, and early in November Mr. Sampson Gamgee will communicate a paper on Wounds and Fractures. The evening of Nov. 20th will be set apart for the discussion of points in thoracic surgery. Later on Mr. Edmund Owen will open a discussion on the Treatment of Cervical Caries, with the special view of ascertaining to what extent Sayre's "jury mast" is being employed at the present day. Dr. Heneage Gibbes has promised a demonstration of Bacteria. The builders are already at work upon the property which the Society has recently acquired next door to its home in Chandos-street, and when all is finished the Society will be well and permanently housed. The Medical Society of London, though an old one, is by no means infirm; indeed if the practical value of its communications and the vigour of its discussions count for anything, it appears to be growing younger with each returning session.

## THE HUNTERIAN MUSEUM.

THE Museum of the Royal College of Surgeons has been in the hands of painters and cleaners since the beginning of August, and may remain in their possession for two months longer; the work is, however, sufficiently advanced to afford some idea of the final effect. The rooms are being painted not only with a pleasing regard to taste, but also with a view of displaying the treasures of the museum to advantage. The repairs are being conducted under the jealous eye of Professor Flower, the indefatigable curator of the museum.

## BROMINE AS A DISINFECTANT.

IN a paper on the above subject, read at the Berlin Apothecaries' Congress, Dr. Franke of Charlottenburg called attention to the fact that the difference between disinfection and deodorisation has only recently been appreciated by the general public. It is, however, now known that many inodorous substances are highly dangerous communicators of disease. The researches of Dr. Koch have brought to light the fact that a number of so-called disinfectants which have been employed for many years are quite insufficient preservatives against many kinds of disease-germs. Thus of late the search after new and reliable disinfectants has been actively carried on. Bromine has materially decreased in price since its production on a large scale at Stassfurt has made it an article of commerce, and Dr. Franke claims to have succeeded in obviating the difficulties which its strong corrosive qualities and other circumstances placed in the way of its general adoption. By the employment of organic acid combinations of alkalis he has succeeded in obtaining in a fluid form eight-tenths of the volume of bromine. The evaporation of the bromine is, he states, thereby considerably retarded and a permanent disinfection facilitated. For mere deodorisation a comparatively small quantity of bromine suffices, while for real disinfection a greater bulk is required. Experiments made by the Berlin sanitary officials have resulted in the fact being established that three and a half ounces of bromine could disinfect a space of 918 cubic feet against the most inveterate forms of infection, for removing which sulphurous acid had proved unsuccessful. Other experiments showed that for simple deodorisation one-third

of an ounce of bromine, hung up high, is sufficient for a space of 7000 cubic feet. With reference to the use of bromine in the practice of medicine, he remarked that in a gaseous form bromine could be introduced into parts of the body not accessible to any other corrosive agent. In connexion with the corrosive properties of bromine, he stated that petroleum had been accidentally discovered to be a cure for burns caused by bromine in a fluid state.

## PROPOSED SANITARY MUSEUM IN SUNDERLAND.

A PRAISEWORTHY attempt is about to be made in Sunderland to extend the knowledge of sanitary matters amongst the residents in the North of England. The effort is initiated by Dr. Mordey Douglas, senior physician to the Sunderland Hospital for Sick Children, who proposes that the new municipal buildings be made to include accommodation for a permanent exhibition or Sanitary Museum, in connexion with which lectures on health subjects may be delivered from time to time, the discourses to be illustrated by the various exhibits. The proposal is a good one, and worthy of successful realisation.

## PERTHSHIRE MEDICAL ASSOCIATION.

THE fourth annual meeting of this Society was held last week at the Infirmary, Perth. The Council's report showed the Society to be in a flourishing condition, that last year's meetings had been well attended, and the scientific work considerable. Special mention was made of the publication of the first volume of Transactions, and Dr. Urquhart, the editor, was cordially thanked. The Society had petitioned Parliament for further liberty to physiologists and others in experimenting upon animals; and the local members had been addressed on subjects of interest in medical politics. Mr. Fleming delivered the president's retiring address, dwelling chiefly upon the origin and progress of the Society. After some formal business was transacted, the following office-bearers were elected for the ensuing year: Mr. Thom, F.R.C.S.Ed., Crieff, President; Dr. Bramwell, Perth, Vice-President; Dr. Baird, Secretary; Dr. Graham, Treasurer; and Drs. H. W. Laing and Urquhart, and Messrs. Gillespie, Trotter, and Paterson, members of Council.

## FULHAM HOSPITAL.

IN consequence of the prevalence of scarlet fever in the metropolis, this hospital was reopened on the 6th inst. for the reception of cases of that disease. Mr. R. D. R. Sweeting has been reappointed medical superintendent. Meanwhile it may be noted that the committee which moved successfully, a few months ago, for an injunction to stop the reception of small-pox cases at the hospital met on Thursday last, and passed the following resolutions:—1. "That the solicitor be instructed to write to the Asylums Board asking if they will confine the admission of the patients to the mile radius, as in the case of the existing injunction." 2. "That the solicitor, Mr. Tomlin, be instructed to take the necessary steps to obtain an injunction against the Asylums Board using the hospital for scarlet fever, typhus, or other contagious or infectious diseases."

## NEW ENTRIES.

As the roll-books of the various metropolitan medical schools are open for fresh entries until the 14th of the present month, statements regarding the number of such entries must necessarily be imperfect prior to that date. We hope, however, by next week to be in a position to publish complete returns of the number of new students in the several schools of London and the provinces.

### EPIDEMIOLOGICAL SOCIETY.

WE understand that at the conversazione of this Society, to be held at University College on the 18th instant, an interesting collection of microscopical preparations illustrative of the pathology of zymotic and parasitic diseases will be exhibited (on the invitation of the President, Dr. Buchanan) by Drs. Klein, Cobbold, Stephen Mackenzie, Professor Axe, Mr. Malcolm Morris, and others.

### PATHOLOGY IN EDINBURGH.

OUR Edinburgh correspondent informs us that Dr. Bryan Waller, Lecturer on Pathology in the Extra-Academical School, is also a candidate for the office of Pathologist to the Edinburgh Royal Infirmary. His name was accidentally omitted from the list of candidates which we published last week.

TYPHOID FEVER is stated to have broken out among the men of the metropolitan police located in Portsmouth Dockyard. The police are quartered in a new pile of buildings, which has been erected in the Extension Works. The outbreak having been attributed to impure drinking-water, Major Grove, the superintending engineer, has written to exonerate the Water Company. He remarks that a report received from the Admiralty chemist upon several samples of the water supplied to the police quarters in question states that, after testing, he finds no difference between them, and that the water is of excellent quality as regards freedom from organic impurity.

ON Monday last H.S.H. Prince Edward of Saxe-Weimar, the General commanding the Southern District, accompanied by the Countess Domberg, visited the Royal Victoria Hospital at Netley. They appeared to take a deep interest in the wounded and invalids from Egypt now under treatment in that national establishment, and expressed themselves much pleased with the general arrangements and the care taken to promote the comfort and welfare of the inmates.

IN reference to a paragraph which appeared in the *City Press* of Oct. 7th, criticising the conduct of visitors at the soirée held at Guy's Hospital on the 2nd inst., the following, we are informed, are the facts:—During the evening some one strayed upstairs into the wards, and was followed by others. As soon as it was known by Dr. Steele, the superintendent, that this had occurred, it was immediately stopped, and the ward doors ordered to be locked.

OUR spirited contemporary, the *Sanitary Engineer* (New York) is publishing a series of articles descriptive of the elaborate sanitary arrangements in the residence of Mr. Cornelius Vanderbilt. The papers when completed will be interesting as showing what may be effected by scientific contrivances, designed to promote health and comfort, when the cost of them is not a consideration.

AT the last weekly meeting of the Metropolitan Board of Works in Spring-gardens, the tender of Messrs. Pearson and Son for £33,990 was accepted for the execution of an additional relief line of sewer on the south side of the Thames, with an outlet into the river at Deptford-green.

AN official despatch from Manilla, dated Oct. 7th, gives the average number of fatal cases of cholera as from 30 to 40 a day in the town and 12 in the suburbs. The epidemic, though declining in some of the provinces of the island, is increasing in others.

THE accounts of the spread of yellow fever in Texas are not reassuring. Though the epidemic is declining at Brownsville, Pensacola is suffering terribly from the scourge. The latest advices give 1300 as the present number of cases, whilst 113 deaths have occurred since the disease first broke out.

T. P. ANDERSON STUART, M.D., assistant to the Professor of Physiology in the University of Sydney, N.S.W., has been elected to the Chair of Anatomy and Physiology in that University.

DR. VANS CLARKE, medical officer of H.M. Convict Prison, Millbank, has been appointed Governor and Medical Superintendent of H.M. Convict Prison for Females at Woking.

THE Secretary of State for India has appointed Deputy Surgeon-General Francis Day, late Inspector-General of Fisheries in India, to the charge of the Indian department of the forthcoming Fisheries Exhibition.

WE understand that Mr. Redgrave, Her Majesty's Chief Inspector of Factories, is at the present time directing his attention to the arrangements connected with the white lead manufacture in Newcastle and its vicinity.

DR. CAMERON PIGGOT has been elected Lecturer on Chemistry and Pharmacy, and Dr. Amanda E. Taylor has been appointed adjunct to the Chair of Materia Medica and Therapeutics at the Women's Medical College of Baltimore.

BY the will of the late Mr. F. M. Balfour, £1000 is bequeathed to Dr. Michael Foster, to be applied by him to the promotion and encouragement of the study of physiology.

THE epidemic of typhoid fever at Bangor is reported to be showing signs of abatement, both as to extent and intensity.

## Public Health and Poor Law.

### LOCAL GOVERNMENT DEPARTMENT.

#### REPORTS OF MEDICAL OFFICERS OF HEALTH.

*Mid-Cheshire.*—Mr. J. Makinson Fox has issued his annual report for the Mid-Cheshire combination, which consists of six urban and four rural sanitary districts. According to the last census return the population of the district was 135,749, it having increased from 120,659 in 1871. The birth-rate for the entire district amounts to 33.1 per 1000 inhabitants; and Mr. Fox finds it necessary, in two separate portions of his report, to warn the people against giving heed to the Malthusian theory that the multiplication and preservation of infantile life should not be regarded as an unmixed benefit. He maintains, on the contrary, that the tendency of such a theory is purely mischievous, and that it can only be destructive of all healthy enterprise, besides proving injurious to the morals of the community. He very properly congratulates several of his authorities on the circumstance that the infantile death-rate has decreased, and he regards this as a sure indication of that sanitary progress which goes hand in hand with the well-being of the inhabitants. The death-rate for the entire district has undergone a diminution, amounting only to 15.5 per 1000, and that from the seven principal zymotic diseases is as low as 0.92 per 1000. In the Northwich rural sanitary district the need for the provision of an infectious hospital is pointed out. Mr. Fox, however, presses for the erection of a wooden hut, and he considers that the publication by the Local Govern-

ment Board of a report which, amongst other matters, quoted an opinion as to the good results following the provision of such a hospital in a certain district, may be regarded as implying that the board approve such buildings, if they do not, indeed, hold them up for imitation. The experience quoted as to wooden hospitals and their use in the report on the Use and Influence of Hospitals for Infectious Diseases, which has just been issued, makes it, however, clear that the Local Government Board hold no such view, and it seems evident that wooden huts, as ordinarily constructed, are not adapted to the more severe of our winters. In the Lymm urban district an arrangement to use the Warrington infectious hospital has not turned out satisfactorily, and it is clear that the distance between the two places will prevent such use of the building as can alone be regarded as meeting the wants of the district. On the whole the sanitary circumstances of this combined area are favourable, and the record given of the works, such as the provision of a wholesome water-supply, which have been completed or are in progress, afford, together with the diminishing mortality, a crucial indication of the progressive sanitary improvement which is steadily being effected.

**Birmingham.**—Dr. Alfred Hill in his last quarterly report refers to a renewed prevalence of small-pox in the borough, some forty-three cases having been admitted into the borough hospital. He further explains to the Corporation that the first case treated in the borough this year came from the neighbouring sanitary district of King's Norton; and he considers that the importation of cases, even into hospital, from the surrounding districts is fraught with danger, and that the authorities of those districts ought to provide themselves with separate hospital accommodation. As regards these particular districts, and apart from the general question of combination in the provision of hospitals, we fully concur in Dr. Hill's view; and it is to be hoped that the decision now arrived at to refuse admission to such cases may have the desired effect of securing isolation-provision in the sanitary districts around the borough. But so long as this provision remains in abeyance, Birmingham will probably be subjected to even a greater risk from the uncontrolled centres of infection about its boundaries than it has been from the reception of infectious cases into its hospital, where further extension was prevented. It is certain that the Corporation ought not to be placed in this awkward dilemma by the failure of its neighbours to take the needed steps for the prevention of epidemic disease.

**Islington.**—According to Dr. Meymott Tidy's annual report for Islington, that parish had in 1881 a population of 282,865, as opposed to 10,212 in the year 1801. The number of inhabitants per house is 8.3; the births have been exceptionally low—namely, at the rate of 35.0 per 1000; marriages have been at the rate of 16.1, and deaths at the rate of 18.0 per 1000. Having regard to the steady increase in the population, this death-rate, the lowest experienced for some years past, must be regarded as very satisfactory. In common with the remainder of London, Islington experienced last year an epidemic of small-pox. The total number of cases which came under notice was 797, with a death-rate of 16.2 per cent. That rate varied, however, materially according to the amount of protection afforded by vaccination. Amongst the unvaccinated the rate was 50 per cent; amongst those alleged to have been vaccinated, however imperfectly, it was only 12.5 per cent. In dealing with the question of the isolation of the infectious sick, Dr. Tidy refers to the unfortunate distinction between paupers and non-paupers in connexion with the use of the hospitals belonging to the Metropolitan Asylums Board. It has often been pointed out that these hospitals, though professedly used for paupers only, do, as a matter of fact, receive non-paupers to the extent of 90 per cent. of their total admissions, and Dr. Tidy says that the percentage of non-paupers from Islington is even greater than that from the metropolis as a whole. Having regard to these facts it becomes obvious, as pointed out in the report, that the poor for whom hospital accommodation is so essential should be provided with it free of cost, and the question of pauperism should not be raised when the point at issue relates to the protection of the public from infection. We have already adverted to the inspection of metropolitan bakehouses since that duty was transferred from the vestries to the inspectors of factories, but we may here add that the details given by Dr. Tidy fully confirm his view that the average three visits a year by the local sanitary officers had led to better results than the much more occasional vi- of

the Government inspector have as yet brought about. In this matter, it is urged, local registration was wanted, and not that centralisation which tends so effectually to remove local responsibility and hence to lower the general efficiency of local self-government. Separate reports are appended which show how effectually the tent hospitals tided over the emergency which the small-pox epidemic of last spring and summer had brought about.

**Rochdale.**—In a special report, Mr. Henry, the medical officer of health, gives certain statistical information concerning the late small-pox epidemic on which we recently commented. Out of a total of 906 cases the death-rate was 11.59 per cent. Amongst 742 vaccinated cases it was 4.31, amongst 54 doubtful cases 24.1, and amongst 107 unvaccinated cases it was 56.1 per cent.; whereas not a single fatal case occurred in a revaccinated person. The number of revaccinated patients was 3; the operation had in each case been performed at the age of puberty, and the slight attacks of small-pox, from which they suffered, occurred at the ages of twenty-five, thirty, and forty-six respectively. Mr. Henry estimates that 5 per cent. of the population of the borough are unvaccinated, and, according to his estimate, it would appear that small-pox attacked 11.3 per 1000 of those who had been vaccinated, however imperfectly; whereas it attacked 31.1 of the unvaccinated.

**Paddington.**—The report of Dr. Stevenson for the year 1881 is one of considerable interest. He is able to give a very creditable account of the sanitary condition of the parish; the annual death-rate being 15.7, as against 21.2 per 1000 for all London and 19.5 for the West districts. In the matter of small-pox, which was the special discredit of the metropolis, he has to record only seven deaths in Paddington. There was in the fourth quarter an unexplained prevalence of typhoid. The report abounds in very instructive tables of all kinds regarding the purity of the different water-supplies, population of areas, deaths from the principal zymotic diseases and from all diseases, &c.

## VITAL STATISTICS.

### HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns, 5513 births and 3228 deaths were registered during the week ending the 7th inst. The annual death-rate in these towns, which had been equal to 20.8 and 20.6 per 1000 in the two preceding weeks, further declined last week to 19.9. During last quarter the death-rate in these towns averaged 20.6 per 1000, against 23.2 and 20.5 in the corresponding periods of 1880 and 1881. The lowest death-rates in these towns last week were 12.6 in Halifax, 14.2 in Bristol, 14.4 in Huddersfield, and 14.7 in Norwich. The rates in the other towns ranged upwards to 26.8 in Manchester, 27.0 in Blackburn, 27.7 in Birkenhead, and 32.0 in Sunderland. The deaths referred to the principal zymotic diseases in the twenty-eight towns were 488, showing a further decline from the numbers in recent weeks; 132 resulted from diarrhoea, 119 from scarlet fever, 78 from "fever" (principally enteric), 70 from whooping-cough, 52 from measles, 30 from diphtheria, and 7 from small-pox. No death from any of these diseases was recorded in Huddersfield, whereas they caused the highest death-rates in Preston, Blackburn, and Sunderland. Diarrhoea was proportionately most fatal in Blackburn and Preston; scarlet fever in Sunderland and Sheffield; measles in Sunderland and Birkenhead; whooping-cough in Blackburn; and "fever" in Sunderland and Portsmouth. Of the 30 deaths from diphtheria in the twenty-eight towns, 22 occurred in London and 3 in Leeds. Small-pox caused 4 deaths in London and its outer ring of suburban districts and one each in Birmingham, Liverpool, Hull, and Newcastle-on-Tyne. The number of small-pox patients in the metropolitan asylum hospitals, which had been 79 and 80 on the two preceding Saturdays, was again 79 at the end of last week; 14 new cases of small-pox were admitted to these hospitals during last week, against 10, 13, and 17 in the three previous weeks. The deaths referred to diseases of the respiratory organs in London, which had in the four preceding weeks increased from 178 to 300, declined again last week to 253, and were 8 below the corrected weekly average. The causes of 81, or 2.5 per cent., of the deaths in the twenty-eight towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Brighton, and in four other smaller towns;

while the proportions of uncertified deaths were largest in Oldham, Preston, Hull, and Sunderland.

#### HEALTH OF SCOTCH TOWNS.

The annual death-rate in the eight Scotch towns, which had been equal to 18.1 and 21.0 per 1000 in the two preceding weeks, further rose to 22.3 in the week ending the 7th inst., and exceeded by 2.4 the mean rate during the week in the twenty-eight large English towns. The deaths referred to the principal zymotic diseases in these Scotch towns, which had been 83 and 117 in the two previous weeks, declined again to 107 last week; they included 36 from diarrhoea, 23 from whooping-cough, 17 from scarlet fever, 17 from diphtheria, 9 from "fever," 5 from measles, and not one from small-pox. The death-rate from these principal zymotic diseases averaged 4.6 per 1000 in the eight towns, and exceeded by 1.6, or more than a half, the rate from the same diseases in the large English towns. The highest zymotic death-rates in the Scotch towns last week occurred in Perth and Greenock. The 36 deaths attributed to diarrhoea showed a further increase of 2 upon those in the two previous weeks, and exceeded by 50 per cent. the fatal cases in the corresponding week of last year. The fatal cases of whooping-cough, which had been 13 and 17 in the two previous weeks, further rose to 23, of which 16 occurred in Glasgow, and 3 in Greenock. The 17 deaths from scarlet fever showed a decline of 5 from those in the previous week, and included 8 in Glasgow, 4 in Edinburgh, and 2 both in Dundee and Paisley. The 17 fatal cases of diphtheria also showed a decline; 7 were returned in Glasgow, 4 in Greenock, and 3 (Dr. Littlejohn reported but 2) in Edinburgh. Six of the 9 deaths referred to "fever" occurred in Glasgow, and 2 in Perth. Two more fatal cases of measles were returned in Dundee. The deaths referred to acute diseases of the lungs in the eight towns, which had steadily increased from 61 to 102 in the four preceding weeks, were again 102 last week, which exceeded by 6 the number attributed to the same diseases in the corresponding week of last year.

#### HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 26.1 and 23.7 per 1000 in the two preceding weeks, further declined to 19.9 in the week ending the 7th inst. During the thirteen weeks of last quarter the death-rate in the city averaged, however, 23.1 per 1000, against 18.6 in London and 17.8 in Edinburgh. The 133 deaths in Dublin last week showed a further decline of 25 from recent weekly numbers; they included 7 which were referred to diarrhoea, 4 to whooping-cough, 2 to "fever," one to measles, and not one either to small-pox, scarlet fever, or diphtheria. Thus 14 deaths resulted from these principal zymotic diseases, against 28, 20, and 15 in the three preceding weeks; they were equal to an annual rate of 2.1 per 1000, while the rate from the same diseases was equal to 2.8 in London and 3.4 in Edinburgh. The fatal cases of diarrhoea, which had steadily declined from 19 to 8 in the five previous weeks, further fell to 7 last week; they were equal to a rate exceeding that which prevailed in London, although considerably lower than the rate from the same cause in Edinburgh. The 4 fatal cases of whooping-cough and the 2 of "fever" showed an increase upon the numbers in the previous week. The deaths both of infants and of elderly persons were considerably fewer than in any recent week. The causes of 11, or rather more than 8 per cent., of the deaths registered during the week were not certified.

#### THE SERVICES.

ARMY MEDICAL DEPARTMENT.—Surgeon-Major Edward Litton Low, M.B., is granted retired pay, with the honorary rank of Brigade Surgeon.

BENGAL MEDICAL SERVICE.—To be Surgeons: Richard Havelock Charles, M.D., George Duncan, William Ainley Sykes.

MADRAS MEDICAL SERVICE.—To be Surgeons: Edwin William Reilly and James Scott.

BOMBAY MEDICAL SERVICE.—To be Surgeons: Robert William Steele Lyons, M.D., John Patrick Barry, Alexander Vase Anderson.

ADMIRALTY.—In accordance with the provisions of Her Majesty's Order in Council of April 1st, 1881, Fleet Surgeon John Mulvaney has been placed on the Retired List of his rank from October 6th; Staff Surgeon Ernest Arthur Hudson has been placed on the Retired List of his rank from Oct. 3rd.

Staff Surgeon William Labdon Powell has been promoted to the rank of Fleet Surgeon in Her Majesty's Fleet, with seniority of September 24th, 1882.

The following appointments have been made:—Fleet Surgeon Belgrave Ninnis, to the *Duke of Wellington*, additional, for transport service; Surgeon William G. K. Barnes, to the *Impregnable*, vice Surgeon M'Carthy; Staff Surgeon Alfred G. Delmege, to the *Constance*.

#### PROFESSOR LISTER ON THE APPLICATION OF A KNOWLEDGE OF HYDROSTATICS AND HYDRAULICS TO PRACTICAL MEDICINE.

PROFESSOR LISTER, F.R.S., delivered an address to the Medical Society of University College on Wednesday, the 11th inst., in the Botany Theatre of the College. There was a large attendance of students, who evidently highly appreciated the address, and gave a very warm welcome to Mr. Lister on this visit to his *alma mater*. Referring to Mr. Beck's remark, in his excellent introductory lecture, that physiology is the application of chemistry and physics to the study of life, Mr. Lister said that it would naturally be expected that physics would be one of the subjects in which medical students would be compelled to show a certain amount of proficiency. By the latest regulations of the Medical Council students could be registered without giving evidence of any knowledge of physics, and as this subject was not required by the Royal College of Surgeons, these students could, and no doubt would, become registered practitioners without such training. In view of this he proposed to show some of the practical uses in medicine of a knowledge of the simple facts of hydraulics and hydrostatics.

Mr. Lister then first referred to the fact that fluid always maintains the same level in communicating tubes of different calibre, and from that passed on to describe the "hydrostatic paradox" and the Bramah press. As a practical application of this principle he adduced the treatment of a wound of one of the palmar arches. In such a case it was necessary to enlarge the wound sufficiently to see the exact bleeding point, and to place the apex of a graduated compress exactly on this point; for if the compress were inaccurately applied, the blood finding its way out of the wounded artery would convert the wound into a kind of Bramah press, and either force up the compass or distend the interstices of the softer tissues. From this Mr. Lister passed on to consider some of the simpler facts about fluids in motion. For this purpose he had a vessel of coloured water raised above the table, from which depended a rubber tube connected at its end with a fine glass nozzle. Allowing the fluid to flow through this apparatus, he noted the height of the jet of water, and then replaced the middle of the tube by an equal length of tube of double the diameter and four times the capacity, and pointed out that, the force remaining the same, the height of the fountain of fluid was practically the same. He used this experiment to show that large varicose veins do not increase the labour of the heart or impede the return of blood to the heart, and that those writers who made such statements were evidently ignorant of simple physical laws. He next held the tube at various elevations, and showed that the position of the tube did not influence the height of the fountain or the flow of blood through the tube, and therefore the effect on the blood circulation of raising or depressing a limb could not be explained on simple hydraulic principles, except in so far as the increased or diminished blood-pressure might cause distension or shrinking of the blood vessels. And how were the facts to be explained, that raising the head of a debilitated patient may cause syncope and anemia of the brain, and depressing the head of a fainting person will infallibly cure the faintness and restore the circulation in the brain? What was

wanted was relaxation of the arteries; the mere action of gravity would tend rather to the dilatation of the veins, and as the brain is contained in a closed rigid cavity, it was impossible to explain the facts on mere hydraulic principles. Mr. Lister stated that many years ago he had a horse slung and laid bare one of the metatarsal arteries; if, now, he were held with the foot dependent the wound bled freely, and the artery was dilated and pulsated freely, while when the horse was inverted and the hoof raised in the air the wound ceased to bleed, and the artery contracted and ceased to pulsate visibly; in the horizontal position the condition was intermediate. Stephen Hales, who was a vivisector, though a divine, had shown that the blood-pressure in the carotid of a horse raised a column of blood seven feet high, and it was clear, therefore, that the effect in Mr. Lister's experiment was not due simply to the action of gravity. Further, when a large artery, such as the femoral, is exposed for the purpose of applying a ligature around it, the vessel is seen to be of a constant size; the pulse does not affect its calibre even when that is measured accurately by calipers; the vessel becomes slightly elongated, but the circular muscular fibres do not permit of lateral yielding of the vessel to any degree, and yet the blood is altered enormously during the cardiac systole. In reference to this, Mr. Lister warned his hearers against being misled by certain pulse-tracings in physiological works, in which the effects of respiration on the pulse were shown by large curves, and that of the cardiac systole by only short notches in the line, as if the effect of respiration on the arterial pressure was much greater than that of the heart. The explanation was that the effect of the heart's contraction took some time to show itself, and before it was fully recorded by the apparatus it was interrupted by the diastole. He had himself, many years ago, performed the following experiment:—Tying into the external carotid artery of a dog a glass tube with an aperture less than one-hundredth of an inch in diameter (so that the loss of blood should be insignificant), he directed the fine fountain of blood on to a sheet of white paper, which was regularly moved along; in this way a tracing was made by the blood itself, which showed that the arterial pressure during systole was double that during diastole.

From these facts it is evident that we must look to the vaso-motor system to explain the cause and cure of a fainting fit by position of the head, and the effects of position upon the blood-flow. When a limb is raised, blood flows down by gravity and the veins are relaxed, and we can imagine that an afferent stimulus is thus excited which reflected along the vaso-motor nerves contracts the arteries. If, however, the tissues are kept for a long time ill supplied with blood, there is such a demand set up for this fluid that the vessels dilate even in spite of the elevated position of the limb, which originally caused anemia. This was illustrated by the well-known experiment of keeping one arm raised above the head and the other pendent, the former becoming pale and the latter turgid. An elastic band was then rapidly wound round the upper part of the elevated arm, and when, after a few minutes, this was removed, the whole limb became suffused and redder than its dependent fellow. Illustrations of the working of this principle were to be seen in the sequence to the ligature of a large artery, the limb at first becoming cold and pale from mechanical cutting off of the blood supply, and then hot and suffused from dilatation of the vessels as a result of tissue-starvation. For the same reason, in piles and affections of the pelvic viscera raising the lower limbs gave great relief, for the contraction of the arteries was not limited to the limbs, but spread to the vessels of the pelvis. As a further instance, he mentioned the case of a man who suffered extreme pain in his testicles when in an upright position, but was immediately relieved by sitting down and putting up his feet. Raising the arms above the head, too, was a well-known means of stopping epistaxis, and succeeded, because the contraction of the arteries of the arms spread by sympathy to those of the Schneiderian mucous membrane. Mr. Lister concluded by stating that he hoped that the few illustrations he had been able to give would show the value of a knowledge of hydrostatics and hydraulics, especially as indicating where physiological effects were produced by other than physical causes.

The new isolation hospital for small-pox patients, erected at Barr-lane, Newcastle-on-Tyne, is stated by Dr. Armstrong to be full.

## THE MINUTES OF EVIDENCE BEFORE THE ROYAL COMMISSION ON MEDICAL ACTS.

### THE INEQUALITY OF THE MEDICAL AND SURGICAL EXAMINATIONS.

THE following evidence of Dr. HALDANE on the rejections of ill-prepared students by the Royal College of Physicians, Edinburgh, in addition to that published in THE LANCET of September 23rd, deserves publication and attention.

2684. (*Professor Turner.*) I think you have had large experience for many years as an examiner in the Royal College of Physicians, Edinburgh?—I have.

2685. A statement has been made to the Commission that a considerable number of students who have obtained their education in England come to the Edinburgh College of Physicians for the purpose of obtaining a licence in medicine; is that so?—That is the case.

2686. The statement has also been made that the students who come from England to the College of Physicians of Edinburgh are ill-prepared students, or students who have failed in London; have you any knowledge on that matter?—That many of them are ill-prepared I can answer for from the number of rejections that take place.

2687. Have you got any facts to lay before us as to the rejections which take place?—I have. I analysed the candidates who came up for the single qualification during the course of last year, 1880.

2688. (*Chairman.*) Is that for the first examination?—No, the final examination. I find that 191 candidates came forward, and they were classified as follows:—100 members of the Royal College of Surgeons of England appeared for examination, and every one of those had passed an examination in medicine before he came to us; but of this number 22 were rejected—22 per cent. of those men were rejected.

2689. (*Mr. Simon.*) In medicine, do you mean?—This was our final examination. I can give afterwards the subjects on which every man was rejected, but in the first place I am speaking of merely the general result of the final examination—22 per cent. of the members of the Royal College of Surgeons of England were rejected. Then we also take up men who have passed everything before the College of Surgeons of England with the exception of medicine; the registrar, Mr. Trimmer, sends a certificate stating they have passed upon everything but medicine. Of those candidates we had 24; seven of those 24 were rejected, or 29 per cent. That is a somewhat higher percentage of rejections than in the case of the members. Then 25 licentiates of the Royal College of Surgeons in Ireland came up; of these nine were rejected, or 36 per cent.; six licentiates of the Royal College of Surgeons of Edinburgh, and all of these passed; 15 of the licentiates of the Faculty of Physicians and Surgeons of Glasgow came up, and seven were rejected, or 46·6 per cent.; eight licentiates of the Apothecaries' Society of London came up, and they all passed; four men who were holders of Canadian degrees came up, and of those only one passed; nine students came up, and of those five were rejected.

2690. (*Professor Turner.*) When you say that the members of the Royal College of Surgeons of England who appeared before you had passed an examination in medicine, am I to understand that they had a licence in medicine?—No.

2691. But that they had passed an examination in medicine before the Royal College of Surgeons in England?—Exactly; the Royal College of Surgeons in England will not give its diploma to anyone who has not passed an examination in medicine. But as I have said before, they will put a man down as having passed in all his subjects and give him his diploma when he has passed in medicine somewhere else; and these are the men who come to us with the certificates of Mr. Trimmer. There were twenty-four of them, and they had not been examined in medicine at all.

2692. I think you referred to a hundred?—191 altogether; that is the total number. There were 100 members of the College of Surgeons of England who came up.

2693. The point I want to get at is this: Can you give us any information as to where these gentlemen had passed their examination in medicine. I mean these gentlemen that you found unqualified in medicine?—Before the College of Surgeons of England. They have, I think, two special ex-

aminers in medicine. I think two is the number; I am not quite sure.

2694. Have you formed any conclusion in your own mind as to the quality of the examination of your own body, looking at it in comparison with the examinations in medicine which these various candidates that you have referred to had passed at other examining boards? Have you formed any comparative idea of the value of your own examination?—Certainly. The conclusion to be drawn is that our examination in medicine must be very considerably higher than the examination by the College of Surgeons of England. Of course a man is not so thoroughly examined, I presume, before the College of Surgeons of England in medicine, where it is only one subject out of many, as with us, where it is our principal subject; 22 per cent. of those men were rejected.

2695. Then of these gentlemen, members of the College of Surgeons of England, who appeared before you for examination for a licence in medicine, can you state to us the subjects in which they were deficient when they appeared for your examination?—I can. I have taken a note of every one of the 53 rejections; I have no names, of course, but I have the qualifications in one column.

2696. Your table is evidently a table of considerable length, an elaborate analysis of the results of examination of your college. I will not ask you to give in your evidence the whole of the table, but perhaps you could select from it two or three prominent examples, so as to give the Commission an idea of the nature of the table?—Fifty-three candidates were rejected at our final examination, which includes an examination in medicine, materia medica, midwifery, and medical jurisprudence; 19 of the 53 were rejected in every one of the subjects; 13 were rejected in three of the subjects.

2697. Would you name the three subjects?—It is in the table, everything is there. Sixteen were rejected on two subjects, and 5 were rejected upon only one subject; 46 out of the 53 were rejected in medicine.

2698. Displaying ignorance in medicine?—Yes, to such an extent that we could not give them our diploma; 36 failed in materia medica, 39 failed in midwifery, and 31 failed in medical jurisprudence.

### MEDICINE IN JAPAN.

WE are glad to welcome, as a sign of the material progress of scientific medicine in the far East, our Japanese contemporary, the *I-ji-Shimbun*, or "Medical News," a weekly periodical, which has already, under the editorship of Mr. Midzu-moto, of Tokio, reached its second year of issue. The number now before us, dated April the 5th, 1882, may be taken as a good example of the work that the staff and publishers have courageously undertaken in the face of the untimely end that has befallen the previous literary bantlings of Japanese medicine. In form it is a useful compromise between the native and European styles; but although English paper has been substituted for the less convenient Japanese material (which allows the impression to be taken upon only one side of the sheet), and the solid wood blocks of the oriental printer have perforce given place to movable metallic type, the publication presents a rather strange aspect to European eyes, beginning, as it does, at the page that for us would be the last, and printed in complicated characters that run vertically down the page, and are separated into double columns by horizontal lines. The matter, however, in nature and arrangement, bears evidence of a close study of Western models.

The articles, which appear to be carefully written, and well adapted to the requirements of the subscribers, are grouped in sections devoted severally to original contributions, general medical news, official reports, hospital reports, meetings of societies, extracts from foreign periodicals, pharmacological notes, and notices of books.

In the first section is a carefully written account of a dissection of a double monster, accompanied by two good woodcut illustrations, one of which gives a well-drawn scheme of the circulatory apparatus in the fused thoracic-abdominal cavity. In the second section are several items that have an interest as indications of the national progress of the new system, such as the statistical report of the inmates of the Kyoto Lunatic Asylum (an entirely novel institution in Japan); a notification of the official permission accorded to

a provincial medical college, conducted upon the European plan, to give medical qualifications to its pupils; and the announcement of the despatch of Mr. Mayeda, a well-known surgeon attached to the Naval Medical School, to Korea, where it is proposed to initiate the study of Western medicine. These items, small as they may appear, speak volumes for the medical future of a country that only a few years ago was wholly given over to the barbarities of the pretentious empiricism of the Middle Kingdom.

The next section gives a statement in detail of the prevalence of typhoid fever in the past year. From this we learn that 23,552 cases were notified, and of these 5679 were fatal.

This is fitly succeeded by an account of the first meeting of a Sanitary Association, the members of which will indeed find no lack of material for their reforming energies to work upon, and may expect gigantic results in a country where cholera has within the last four years slain its two hundred thousand, and is now engaged in its third biennial campaign; and where typhoid fever, beriberi, and a dozen other filth engendered diseases have for centuries robbed the nation of its strength.

Passing on a stage further, we find hospital practice well represented by a report of a successful operation for strangulated inguinal hernia, by Mr. Sasaki, at Matsuye Hospital of Shimane Ken.

Lastly, the section of extracts includes a few translations from American and English medical journals, amongst which may be noted "The Use of Borax as a Deodoriser" (Dr. Thin), and "The treatment of Nebulæ of the Cornea by the Sulphate of Cadmium." This division of the paper, however, might be extended with advantage.

The originators of this modest publication may be congratulated upon the evidence of strong vitality which it displays. Medical journalism in Japan has had but poor prospects of success hitherto, for although there is no deficiency of practitioners of the art (the number of registrable "doctors" attaining the respectable figure of 65,000), the most charitable calculation has not extracted from the total more than about 800 enlightened spirits who have ventured to sacrifice the classical Chinese laws in favour of that which they designate the "Western system"; and it is to be feared that even this modest ratio of orthodoxy to empiricism would be terribly reduced were the claims of our nominal adherents subjected to serious test. The cause of medical literature must hence necessarily suffer from a poor subscription list; but beyond this it has in the past lacked a sufficiency of willing and competent native contributors, who alone could make the experiment with any hope of success. Happily, the *I-ji-Shimbun* proves that a new era is dawning, and leads us to hope that we shall soon see the results of the work done by the Government in the foundation of the Tokio Medical College, the Naval Medical School, and other institutions conducted by foreign instructors, and in the expenses they have incurred in educating chosen men in the Colleges of Germany and England. The country now has in Drs. Satow, Hashimoto, and Ikeda, who have graduated in Berlin, Mr. Takaki, a Fellow of the English College of Surgeons, Drs. Miyake, Toksuka, Matsumoto, and some others, a strong intellectual force, and it is upon these that the future place of Japan in the medical world will depend. The present journal has laid a good foundation, and is not attempting to run up the edifice too quickly. There is little in the numbers now before us that calls for quotation in our columns; but this is in no degree adverse to its claims as a valuable organ of instruction and intelligence. There are men in Japan who are fully capable of good original work; but, for the present, it is essential that the educational functions of the medical press should be confined within narrow limits, as the practitioners for whose benefit a native journal is especially desirable understand little of any language but their own, and almost nothing of the science of modern investigation. These will look for easily comprehended reports of cases of common occurrence, and well-chosen and carefully simplified illustrations of important facts of diagnostic and therapeutic interest, rather than for pathological theories and details of rare operations. On the other hand, the more accomplished members of the profession can read and digest the European journals in the original, and when this little band has become increased by the reinforcements now in busy preparation it will be time to take a new departure in literature. In the meantime ambition is best served by humility, and we hope to measure in the future years of the life of the *I-ji-Shimbun* the development of those newly awakened faculties of observa-

tion which are already so well manifested in the modest and useful articles which have set a stamp of value upon its earliest volumes.

### WOOLSORTERS' DISEASE.

To the Editor of THE LANCET.

SIR,—For nearly twelve months have we been clear in this neighbourhood of any cases of the above justly-dreaded disease. It appears, however, we have not arrived at the stage of complete immunity, notwithstanding all the precautions which have been adopted—the steeping of unopened bales, washing the wool in a sud of water at from 100° to 120°, passing through rollers, sorting the wool when damp, &c. The whole of these processes had been gone through prior to the wool reaching the workman who has now succumbed to this malady. Whether the washing process had been imperfectly carried out, or what is just as likely, that the workman became infected from having access to other departments where the washing of the wool was conducted, it is difficult to say.

John G—, aged sixty-one, a "filler" (in the combing department) of boxes with brown Van mohair which had been washed and sorted, had been at work for seven years, and had enjoyed previous good health; said to have been always temperate, and looked so. On Thursday the 7th ult. he observed a papule on the outer border of the right radius, two inches above the wrist; he paid no attention to it as he was free from pain. The top of the papule was knocked off on the 9th while cleaning some boxes. On the 10th the papule began to enlarge and became slightly inflamed. Continued to work till late in the evening of the 12th. Got up on the morning of the 13th to go to work, but said he would not go, although he did not apprehend anything serious. In the evening of this day I was called in, and found him lying on his back, looking anxious, pale, and sweating moderately; answered intelligently any questions, no delirium, complained of a little pain in the epigastric region. Above the right wrist I found an eruption about the size of a shilling, having a black sloughing centre with a vesicular rim, about one-eighth of an inch broad, loaded with a sero-sanguinolent fluid, which was trickling down on to the bed. The hand and half way up the arm was oedematous. Tongue moist, coated with white fur. Respiration 33 and shallow; physical examination did not reveal anything abnormal. Pulse 84, regular. Heart sounds very indistinct, could scarcely be heard at all. Bowels loose, from taking some sulphate of magnesia. Urine had just been voided when the bowels were moved, and could not be observed. Temperature in axilla was subnormal. Treatment: Stimulants, beef-tea, and milk ordered; sulphite of soda in drachm-doses every three hours, and a lotion of the same kept constantly applied to the pustule. The patient died seven hours after I saw him.

*Autopsy, twelve hours after death.*—Rigor mortis marked; livid discoloration on back, flanks, and back of left upper arm, whole of left side of neck; left external jugular vein distended; lividity of ears, fingers, and finger nails. Lungs emphysematous, not shrinking back after chest was opened; hypostatic congestion over posterior aspect of both lungs; very small quantity of prune-juice looking fluid, in right pleural cavity, none in left, no pleuritic adhesions; lungs crepitant all over. Heart: Cavity of pericardium contained half an ounce of bloody fluid; right ventricle collapsed and empty, both auricles empty; left ventricular wall thickened, cavities small; all the valves were normal; inner coat of aorta slightly stained, healthy otherwise. Abdominal cavity contained a large quantity of amber-coloured serum; between the layers of the large omentum there was a thick gelatinous deposit, extending over the right half of the omentum, including and covering the transverse colon, and half way down the ascending colon; patches of livid congestion existed in small intestines. Spleen twice as thick as natural, convex surface of capsule was dense, white, and opaque. Kidneys healthy;

the capsules stripped off easily. Liver: surface rough, nodulated, tough, and hard, resisting breaking up by the fingers; right lobe diminished, left lobe not so much altered in size. Bowels healthy, no hæmorrhages; the valvula conniventes were swollen from contained gelatinous material. The glands at the root of the lungs were not enlarged or softened. In removing the pustule on the arm, a quantity of serum which had become gelatinised, was observed beneath.

Microscopic examination of the fluids of the body, notably from the spleen, revealed the bacillus believed to be, by many, the *materies morbi*. Subcutaneous injection with these fluids, containing these bacilli, was fatal to animals, the fluids from these animals again showing the same micro-organism. I am, Sir, your obedient servant,

Bradford, Oct. 1882.

L. S. MACKENZIE, L.R.C.P., &c.

### MONOPOLY OF HOSPITAL APPOINTMENTS BY THE FELLOWS OF CORPORATIONS.

To the Editor of THE LANCET.

SIR,—The following passage on page 447 of your issue of September 16th induces me to address you as to what I feel to be a grievance: "Since the late Mr. Wakley founded THE LANCET to protect the rights of the public and to assert the rights of the profession against encroaching corporations." Also on page 449: "The Act of 1858 broke down the territorial privileges of the licensing bodies, and made a licence valid anywhere in the United Kingdom." The latter is only half the truth. It is quite true that the possessor of any registrable degree or diploma may now practise anywhere in the country without let or hindrance; but it is equally true that he cannot, unless he be a Fellow or Member of the Royal College of Physicians, hold any appointment in London which is worth having, and very few, indeed, in the provinces. The same obtains if not in Scotland at least in Edinburgh, where very recently a candidate was disqualified from competing because he was not a Fellow of the Edinburgh College of Physicians. I consider that this system is a grievous abuse; for it cannot be pretended that those who hold the degrees of Edinburgh, London, Dublin, Glasgow, Oxford, and Cambridge are, in point of scientific acquirements, inferior to members of the Colleges of Physicians; and that the exclusion of graduates of the universities from hospital appointments is a breach or evasion of the letter and spirit of the Medical Act before mentioned. It may be urged that private bodies have a right to nominate their own officials. I concede this, but must point out that, with the exception of Guy's, St. Bartholomew's, and St. Thomas's, all the other hospitals in London participate in public charity, and receive a share of Hospital Sunday collections, and that the same obtains in the provinces where, I imagine, there are no endowed institutions. But the fact remains that not only does this monopoly exist, but it goes on steadily increasing, and to this grievous abuse I hope you will turn your attention. There can be no possible objection to imposing certain conditions on hospital physicians—i.e., that they shall not be in partnership with anyone, and that they shall not practise midwifery. But beyond this, and a prohibition against dispensing, I do not see at present any reason for going. I apprehend that the statistics of cottage hospitals, which as a rule are not under the control of Fellows and Members of the Colleges, will show that, making allowance for country air, the patients in them do just as well as in those institutions where only Fellows and Members of the Royal College of Physicians are allowed to practise. In writing to you I do so in confidence, as I am fully aware of the boycotting propensities and practices of the Royal College of Physicians. I have been repeatedly urged to join them by Members and Fellows, and had it more than hinted that they were very clannish as a body and would have nothing to say to outsiders; and this I believe, from my personal observation, to be the case. Setting up for purists in practice and ethics, I know of one Fellow who has his name on a huge placard (of the style of "no trespassers allowed") at a considerable distance from his house, and another who does not disdain to put up a fracture when there are surgeons in plenty at hand.

I am, Sir, yours, &c.,

M.D. Edin. and Paris.

Oct. 1882.

## THE TEMPERATURE AND PULSE IN REMITTENT FEVER.

*To the Editor of THE LANCET.*

SIR,—During my three years' tenure of office as surgeon of the Royal Naval Hospital, Malta, ending in June last, numerous cases of Mediterranean remittent fever were received for treatment from the crews of H.M. ships on the station, and during the early months of this year the ships in the harbour sent to hospital an unusually large number of very severe cases with a marked tendency to develop complications.

The following fact presented itself to my mind very forcibly; and as it seems of considerable importance in the early diagnosis of complications in these fevers, I deem it worthy of record, not having noticed it in any of the works on the subject I have read—viz., that although the temperature often rose to 104° or 105° the pulse remained almost normal in uncomplicated cases. If, however, a complication set in, such as pneumonia, hepatic, or cerebral congestion, the pulse at once rose far above the normal. Of course when the temperature was 104° or 105° the patient was as it were on the brink of a precipice, and complications were then very liable to occur; but while the pulse did not exceed 80, even though the temperature was 104°, no complication was found to exist, and a favourable prognosis could be made.

I am, Sir, yours truly,

J. WILSON, M.D., Surgeon R.N.

H.M.S. *Hecla*, Oct. 4th, 1882.

## THE WAR IN EGYPT.

*(From our Special Correspondent.)*

THE brilliant campaign in Egypt, conducted by Sir Garnet Wolseley, having terminated dramatically with the general action of Tel-el-Kebir, the flight and surrender of Arabi, the forced cavalry march to Cairo, and the capitulation of all the places in the country that held out against us, has been followed by a pause sorely needed by the troops and all concerned. Events have hitherto succeeded one another with the rapidity of telegraphy. This war, as far as the military operations are concerned, began and culminated with a rush.

Probably no campaign undertaken by England has been characterised by a greater amount of preparation: field and base hospital material and *personnel*, medical and surgical appliances, and what are known as medical comforts, were shipped in abundance, accompanied by a body of well-trained nurses, most expensively fitted-up hospital ships, ice-making machines, and what not. That all these aids and appliances to our latest field service system were not utilised to the extent they might have been has been mainly attributable to two facts—viz., the necessarily precipitate and impetuous nature of the military operations and the want of adequate transport.

The field medical service of modern warfare is based upon a few simple principles capable of being understood by anyone. In civil life, in our civil hospitals for example, there is ample room for the exercise of individual skill and the leisurely application of surgical science. But in war it is far otherwise; there is room, indeed, for the exercise of these qualities, but organisation and system dominate everything else. If the administration be not based upon sound and simple principles no amount of individual skill, nor of supplies and appliances, will be of the least avail. The principles are then to evacuate the sick and wounded men from front to base, always—that is, in the direction they must take—in a continuous stream; and to provide for the requirements of the fighting force in front such an amount of hospital accommodation and medical aid as shall be adequate, while it is at the same time as mobile as practicable. The machinery by which all this is accomplished is a system of field or movable, and base or general hospitals, including in the latter any posting hospital accommodation that may be available and utilised. The very pivot of this system, without which its distinctive character of field and

base hospitals is lost and its effectiveness for work has no existence, is that, in military parlance, no part of the force should ever lose touch of a field hospital or some section thereof; for carrying this out in its integrity transport is obviously essential. People are very apt to forget this fact, but it is the very pivot of the whole thing; the usefulness, the adaptability of a field hospital system to meet every requirement, is in direct ratio to its facility of movement. Let that be assured, and all is easy; the splitting up of a field hospital, be its size what it may, is entirely a question of pre-arrangement and packing; medical and surgical stores, *personnel* and material, in brief, should be capable of meeting the wants of ten or ten hundred patients. And the converse of all this is true: in proportion as you diminish the mobility do you impair the utility of a field hospital, until you deprive it of its essential character, and relegate it to the category of a stationary or base hospital, temporary or permanent, as the case may be. Another principle is that in proportion to the completeness of the organisation and the adequacy, an adequacy to superfluity, of the supplies at the base, will be the adequacy of the supplies distributed in front, and the completeness and facility of the working arrangements in rear. So self-evident are these statements that when reduced to writing they partake of the nature of platitudes. But let the reader remember that promptitude of action was a military necessity in this campaign; that before anything like all the troops had disembarked a portion of the force had marched to the front and fought; another portion had to be hurriedly disembarked and marched to their aid, in order to secure the water-supply and seize the railway; and that from first to last transport was a great difficulty, never entirely overcome, it is true, but diminishing day by day as more and more of canal and railway carriage became available and was in working order. If these facts be borne in mind as essentially necessary to the right understanding of what follows, much needless repetition will be avoided in a narrative not easily compressed at the best, when there is not, paradoxical as it may sound, time to make it shorter. The troops arrived at Ismailia on August 22nd and 23rd, and were actively disembarked on these and the following days. A palace—the Khedive's palace—was hastily turned into a hospital; it was a beautiful building, but a palace, and never intended for a hospital, and without the sanitary essentials or conveniences of one. A portion of a field-hospital, No. 3 field-hospital, under Surgeon-Major Beattie, was disembarked on the 23rd and took possession of this building, which had scarcely been done when the sick and wounded began to arrive. The work was very hard,—night and day and every day. Everything had to be extemporised from the materials at hand and as they came to hand. A very considerable amount of originality, ingenuity, and energy was brought to bear on the arrangements of this hospital, which in the course of a comparatively short time, after the arrival of the hospital ship *Carthage* on the 28th with the base hospital stores and establishment, became, at the time I saw it under Dr. Oliver Barnett, an admirable hospital—clean, beautifully ventilated, well supplied and well arranged, with a ward atmosphere as sweet and wholesome to the senses as the outside air. This hospital received all those coming from the front, and fed all the transports at Ismailia with their freights of sick and wounded for Cyprus, Malta, or England, the immense majority being sent straight to the latter destination. The amount of work performed at this hospital may be gauged by the fact that, as we were informed, 2667 patients passed through it in the course of a month, 500 or 600 of whom were wounded men. At this hospital a system of antiseptic surgery, as far as its principles admitted of prompt and practical application, was either adopted from the first, or, as in the case of those wounded at the battle of Tel-el-Kebir, continued where it had been already applied elsewhere. The large size of the central hall and staircase, the skylights of the corridors, made by the medical staff to communicate directly with the open air, and the nature of the climate admitting of the windows being kept open night and day, and the freest use of disinfecting agents in the dressing of wounds, kept the hospital air remarkably pure; and we can say, from personal knowledge, that the dry earth system with metal buckets, periodically removed, rendered that part of the building set apart for this purpose perfectly wholesome—in fact, the doors and windows of this part, allowing of free communication with the rest of the hospital, were fully open without any trace of bad odour being discernible. At this hospital arrangements had been pro-

vided for the segregation of cases of infectious disease; and a local sanitary service for Ismailia existed.

Passing over the military events of the 24th, 25th, and 28th of August, we come to those of, and immediately preceding, the battle of Tel-el-Kebir. Had there been ample transport—that is, an ample supply of horses, mules, and carriage—it is believed that the provision in England presupposed as many as five field hospitals, each capable of accommodating 200 patients; but it was clear that it was impossible to make this number available. The sandy character of the soil would not admit of wheeled vehicles for the removal of wounded. The General (Sir Garnet) had matured his plans and settled his strategy, the boldest, and best because the boldest, that could be adopted. On the night march, the attack at dawn of day, and subsequent events there is no need to dwell; but it is essential to bear in mind that the attacking force had the line of railway available in its rear, and a water-carriage system along the canal on its left flank. The medical arrangements were somewhat as follows:—Two field hospitals had been established at Kassassin lock, some eight miles by canal from Tel-el-Kebir. Half a bearer company was attached to each division during the action, and a special cacolet corps to the cavalry division. About eighty dhoolies and dandies with bearers accompanied the force. The Indian contingent advancing on the other side of the canal had its own arrangements. On the night of the 12th the stores and equipment for an advanced dépôt field hospital were sent up the fresh water canal in a flotilla of cutters and flat-bottomed boats, ready to disembark at any point to be fixed upon, and daily supplies of ice were forwarded from Ismailia to Kassassin hospital, where medicines and medical comforts had been provided for the use of the wounded on their arrival from the front. The Surgeon-General was very early in the field directing the medical arrangements, and he subsequently rode over to Kassassin, to satisfy himself that the hospital there was prepared for the reception of wounded. The arrangements at the Tel-el-Kebir dam hospital seem to have answered well. The boats discharged their stores, a hospital of twenty-five tents was formed on a ridge contiguous to the fresh water canal, and the Geneva flag was hoisted on the top of an earth entrenchment evacuated by the enemy. The cutters and boats were thickly littered with hay and drawn up alongside the banks of the canal. From about 9 A.M. to 8.30 P.M. about 200 European patients were received and treated in the hospital, and forwarded in two batches to the Kassassin Lock Hospital. The system of water-carriage is admirably adapted for the transport of wounded men, and everybody was loud in praise of the navy for the careful forethought they brought to bear on the matter. Among the 200 wounded there were seven officers, five of whom were seriously injured, and about 200 cases of wounded Egyptians were also received and attended to, their wounds dressed and the patients prepared for transport by train to Cairo. A very successful attempt was made to administer systematically opium, either by mouth or hypodermically, to every wounded case. Supplies of fluid nourishment, water, and stimulants were also periodically furnished, and the wounds were all treated antiseptically. The wounded were conveyed on stretchers, dhoolies, or dandies, or litters and cacolets, from which they were not, as a rule, removed until their disembarkment at Kassassin Lock Hospital. At this hospital there was a staff of five medical officers with a civil surgeon, who undertook the preparation of all antiseptic solutions and dressings, in addition to three medical officers who came in with the wounded and temporarily aided the staff, the whole, including the transport arrangements, under the supervision of a deputy surgeon-general. Some of the wounded men struck the canal at a point lower down, owing to the field hospital having been passed on as far as practicable to the front, but these were picked up by the boats; and a number of men were transported by train direct to Ismailia, after having been dressed in the field. A large number of wounded Egyptians, in addition to the above, were collected on the field, and conveyed to a field hospital at Tel-el-Kebir railway station, where numerous operations were performed. Two hundred and two were sent to their homes, and the remainder, after being well supplied with necessities, were sent by special train to Cairo under their own doctors.

As I began so I conclude. This campaign has been a rush from its beginning to its close; there has been no finality about anything; it has been here to-day, there to-morrow. No sooner had arrangements been made than a

place, a camp, barrack, or hospital has been evacuated; the strain, physical and mental, is allowed on all hands by those who have had much experience of war to have been extreme; and now that the actual fighting and marching are over, the doctor's work has begun in real earnest. There is a normal life to everything, calculated upon its strength of material and its work, whether it be a railway carriage, a steam-engine, a beast of burden, or a man. We do not know how many campaigns a Special Correspondent is capable of going through, but a very few such campaigns as this would soon close the earthly career of an army doctor occupying a responsible position.

## GLASGOW.

(From our own Correspondent.)

ARRANGEMENTS in connexion with our new Children's Hospital are so far advanced that the committee of management have advertised for a medical staff, an event which of course has caused no small excitement among those who think they have a chance of being elected. The hospital is one of eighty beds, and for this are required two visiting physicians, two visiting surgeons, an extra physician, an extra surgeon, and a resident medical officer. The candidates for these posts will be legion and the contest keen, though it is pretty generally understood that canvassing and similar annoyances are rather objected to by the committee who have the appointments in hand. Various guesses are in circulation as to the prospects of certain known candidates; in the meantime it is much easier to say who will not than who will be elected.

There was a death from hydrophobia in the Royal Infirmary last week, the case having run the usual rapid and fatal course. The patient had been bitten by a rabid dog as far back as the middle of March last.

An action for £500 damages has been commenced against Mr. M. G. Cluckie, Surgeon-oculist to the Ferguson Eye Infirmary, Greenock, and Mr. Dobie, house-surgeon to the infirmary. The child, a girl of seven years, died under chloroform before any operation had been performed. Proof in the case is fixed for November 2nd.

The condition and regulation of our tramway cars was very heartily and justly condemned at the last meeting of the Town Council, the discussion being raised by the medical officer's report in connection with whooping cough. Complaints had been lodged at the sanitary office that children suffering from that disease were admitted into the tramway cars, a proceeding which is certainly culpable in the highest degree. Many of the older cars, also, are extremely dirty and absolutely deficient in ventilation. Our cars, being public conveyances, should be better seen to.

## SCOTTISH NOTES.

(From our own Correspondent.)

THE Aberdeen University Court last week adopted the following minute:—"The Court feels that it cannot quit the consideration of Dr. Pirrie's retirement without recording to his honour the character that he has borne throughout a very long career. Being identified with the very commencement of the Aberdeen Medical School, he has been largely instrumental in impressing upon it the stamp it now bears in the medical world. First, as a lecturer on Anatomy in Marischal College; and next, for the period of forty-three years as Professor of Surgery, he has necessarily had a leading part in the education of nearly two generations of medical graduates. His teaching has been characterised by a remarkable power of lucid and impressive exposition; while he spared no pains to make it demonstrative. His zeal and enthusiasm, combined with such teaching ability, effectually secured the attention of his students, by whom he will be respectfully remembered as one of their most valued instructors." Former students of Dr. Pirrie will

heartily endorse this admirable tribute; and it may not be amiss to state that many of them feel the present to be a suitable opportunity for permanently fixing the name of their beloved teacher in connexion with the university, by some substantial memorial.

Dr. Whitelaw's interesting experiment in keeping the public schools open during the epidemic of scarlet fever at Cupar, and in having the school authorities notified as to the families where the fever exists, has not proved successful, on account of "astounding carelessness, deceit, and concealment" on the part of the public. This being so, Dr. Whitelaw recommended the closing of the schools for a temporary period; but the sanitary committee has not seen fit to adopt this course. We have evidently here an example of what is to be expected when compulsory notification is made to bear upon parties other than the parents of the children affected.

The enormous success which Miss Clugston has met with in the West of Scotland in establishing convalescent homes was instanced in two directions last week. The report of the Dunoon Homes shows that during the past year 2599 convalescents have been admitted, 137 were at present in the institution, only two had died, and the remainder had been perfectly restored to health. The financial statement was favourable. Imitation is the sincerest flattery, and it would appear that the Hon. Mrs. Vernon has inaugurated a movement for the purpose of providing a children's convalescent home, to be situated on high ground near Troon. Very influential support is already promised.

The directors of the Fife and Kinross Asylum have agreed to record in their minutes an expression of the gratification felt by the Board at the satisfactory state of affairs shown in Dr. Turnbull's report for the year regarding the boarding-out of chronic cases and the enormous saving to the rate-payers thus occasioned. The twenty-five patients so dealt with represented relief to the assessment of a capital sum of £5000, while at the same time the expense to the parochial rate was lightened. Facts of this class are likely to be quickly appreciated by other directors, who may have hesitated long when the advantage to the patients of the boarding-out system was alone insisted on. The forcible suggestions of the Commissioners regarding this and other matters have been favourably referred to by the lay press in Scotland.

It appears that the quality of at least part of the Dundee water supply is rather suspicious. An exciting argument, lasting several hours, occurred a few days ago over a question as to whether samples from the three sources of the town's supply should be analysed, or whether but one should be so treated. Though a proposal with the latter view was carried, the result of the discussion will be that uneasiness will be felt regarding the quality of the waters, an analysis of which was so obstinately refused by the majority. The filtration of the Monikie water is estimated to cost £15,000.

## IRELAND.

(From our own Correspondent.)

ON the 18th inst. (St. Luke's Day), the annual elections for President, Vice-President, and other office-bearers of the College of Physicians will take place. Dr. Johnston, having served two years as President, retires, and will be succeeded most probably by Dr. William Moore, late Professor of the Practice of Medicine in the School of Physic of the University of Dublin. Dr. Moore is a very distinguished physician, and there is no doubt his election will be favourably regarded by the profession. Dr. J. Magee Finny, the present Registrar, has, I understand, resigned, and Dr. J. W. Moore has been nominated for the post, the emoluments of which are about £100 per annum.

During last year 11,169 persons were inmates of district lunatic asylums in Ireland, of whom 8667 remained at the close of 1880, while 2502 were admitted during the year. The recoveries were 1019, and, if judged by the admissions, would stand at about 40 per cent., but if by the daily average of patients—namely, 8794—at not quite 11½ per cent. The mortality was 7 per cent., less by 0·25 per cent. as compared with last year. As regards the period of life when mental disorders become most manifest, the inspectors, from

the various statistics at their command, place it between twenty-five and thirty-five, in which decade there exists, happily, greater power of recuperation than in any other. As, heretofore, the great characteristic, from a national point of view, between England and Ireland is to be found in the extraordinary difference between the number of married and widowed on the one hand, and the single on the other—viz., 2614 and 6000 respectively, while in 364 the special condition was not ascertainable. No adequate explanation has ever been given of this disparity in the social condition of Irish lunatics.

It is expected that a memorial will shortly be erected to the late Dr. William Thompson, of Lisburn, whose sudden death I referred to recently in these columns. That something of the kind will surely take place there is little doubt, but what the form may be has not yet received any definite shape. It has been suggested that the most useful and appropriate memorial would be a new surgical hospital for Belfast, to be called, for example, the "Thompson Memorial Surgical Hospital," to perpetuate the name of a very distinguished member of the profession. The population of Belfast is about 208,000, and yet there is only one general hospital in the town, which is rapidly increasing in wealth and population. The beds for medical and surgical relief available only amount to 160, which, compared with 350 beds in Cork with a population of 100,578, and other places, show that instead of one general hospital, Belfast requires at least treble its present accommodation.

The memorial window to the late Dr. Edward Peele, whose untimely death from typhus fever was so much regretted, has been erected in St. Patrick's Cathedral, Dublin.

In consequence of the enforced resignation of Dr. O'Reilly, medical officer of Lismore Workhouse, an election for his successor took place last week. There were four candidates, and ultimately Dr. Denneby was elected.

Dr. E. H. Byrne, one of the medical officers of the South Dublin Union, who is about leaving Dublin and intends practising in Australia, was this week presented by his friends with a farewell address. Among those present were several members of Masonic Lodge 245, with which Dr. Byrne was connected, and who presented him with a past-master's jewel and a royal arch jewel.

During the quarter ended June 30th, there were registered in Ireland 32,679 births, equal to a rate of 25·7; and 22,874 deaths. In the same period 45,105 persons emigrated; so that a decrease of 35,300 would appear to have taken place in the population. The registrars report the death of five persons from hydrophobia during the quarter, and refer to the prevalence of rabies in dogs and other animals in twenty-six districts. The information concerning this disease was obtained in reply to a special query addressed to the registrars to furnish any information within their knowledge regarding the prevalence of the disease, and they supplied accurate and recent information to the Government regarding this fatal affection.

Dr. Beamish, who for nearly fifty years held the post of Physician to the Cork Fever Hospital, has been presented with a handsomely illuminated address on the occasion of his retirement.

Mr. John S. McArdle has been appointed Surgeon to St. Vincent's Hospital, Dublin, in the vacancy caused by the resignation of Mr. Kehoe.

## PARIS.

(From our Paris Correspondent.)

As you are an uncompromising enemy to homœopathy, or anything savouring of quackery, I send you the following extract from the writings of Orfila, which you may consider worth reproducing in THE LANCET:—"The mandates I frequently received from courts of justice to analyse medicines compounded and delivered by homœopaths have enabled me to affirm that there existed no appreciable substance whatever in the pretended homœopathic remedies; or if, by chance, the analysis revealed any substance in a certain number of them, the quantity was so small that it may be considered nil; but I know also, and I affirm it on my honour, that, having little confidence in a system which cannot produce good results in a great many

acute affections, many homœopaths administer medicines in allopathic doses, so that the system of Hahnemann is adopted and practised by two sets of individuals. The one who have an unlimited faith in it, practice it without any restriction, and abandon their patients to themselves without taking into consideration the innocuousness, often murderous, of medications which they prescribe; these are pure and fanatical homœopaths. The other, less dangerous when it concerns the treatment of acute maladies, may be qualified clever homœopaths, as they act on the imagination of their patients by the administration of a few globules of extreme dilution, and consequently insignificant at the same time; they bleed, apply leeches, blister, prescribe corrosive sublimate, opium, copaiba, in rational doses, the good effects of which soon become apparent." What was written by the celebrated medical jurist more than a quarter of a century ago holds as good now as it did then.

In a very interesting paper by Dr. Magnan, one of the physicians to the Sainte-Anne Asylum, on the treatment of epileptic patients, he gives the following useful advice:—One should not be in a hurry to set at liberty an epileptic patient who, in previous attacks, had committed acts of violence, as it should not be forgotten that he is liable to commit others in analogous circumstances. If at the commencement they have not been followed by any serious consequences, it is rare that they do not end by being attended with some terrible effects. This, however, is very different from the case of patients affected with melancholy, for they hesitate for a long time before they attempt to commit suicide. Many of these latter are even obliged to drink some intoxicating liquor to excite themselves in order to have the courage to accomplish the act to which they have so much repugnance, and of which they were perfectly conscious, whereas the confirmed epileptic acts otherwise.

Dr. Bourneville, physician to the Bicêtre Asylum, after several experiments to ascertain the effects of the bromide of ethyle in cases of hysteria and epilepsy, has come to the following conclusions: 1. The dilation of the pupil at the commencement of the inhalations of the bromide of ethyle is not constant. 2. The complete muscular resolution is exceptional. 3. Anæsthesia is produced in different degrees, according to the subjects experimented on. 4. The temperature, the secretions, and the general state of the patient do not appear to undergo any modification. 5. The pulse and the respiration are slightly accelerated. 6. Trembling of the limbs in a more or less marked degree during the inhalation may be produced, but it does not persist after the cessation of the inhalation. 7. Hysterical attacks are in general easily arrested by the bromide of ethyle. 8. Epileptic fits may sometimes be arrested by administering the medicine at the commencement of the tonic stage; more frequently, however, the inhalations produce no effect. 9. In epilepsy the regular employment of the bromide of ethyle, administered by inhalations daily during one or two months, greatly diminishes the frequency of the attacks.

All medical men know that it is impossible to touch or titillate the mucous membrane of the larynx without producing very marked reflex effects. The glottis contracts spasmodically, and the whole of the larynx is drawn up with violence. When this organ is irritated by a current of carbonic acid, or by the vapours of chloroform, besides the local reactions, a general state of agitation is noticed. These two anæsthetic agents act nearly in an equal degree in this respect, and irritate very violently at the commencement. When, however, they are applied to the larynx for a few minutes the irritating effects of one or the other become *nil*, or considerably reduced. This is particularly the case with carbonic acid. The above have been the results constantly obtained by Prof. Brown-Séquard by experiments performed by him on animals; and in a paper read by the learned professor at the Academy of Sciences last week he expressed the hope that this discovery would enable medical men to introduce a tube into the larynx, or even the trachea, with impunity. Prof. Brown-Séquard did not notice any bad effects, either local or general, to have been produced by the carbonic acid; neither was there any manifestation of mechanical irritation of the larynx or the trachea in his experiments. He, however, enjoins further researches on the subject before applying carbonic acid in the manner above described, and the institution of further experiments, with the view of ascertaining positively the innocuousness of introducing into the human subject, by the

mouth or nostrils, a large quantity of carbonic acid. It is known, he added, that this gas determines cephalalgia, giddiness, &c., and that a very rapid current of this agent may be applied to the back of the mouth or fauces without producing any dangerous effects. Nevertheless, it is essential to reproduce the experiments, with the view of ascertaining the anæsthetic effects of carbonic acid on the mucous membrane of the larynx.

Paris, October 10th, 1882.

## Medical News.

**APOTHECARIES' HALL.**—The following gentlemen passed the examination in the Science and Practice of Medicine, and received certificates to practise, on Oct. 6th:—

Appleton, Harry, Lizard, Cornwall.  
Bartlett, Benjamin Pope, Hastings.  
Plesse, Charles Henry, New Bond-street.  
Rouse, Rolla Edward, Woodbridge Rectory.  
Winter, Thomas Bussell, Werter-road, Putney.

The following gentlemen also on the same day passed the Primary Professional Examination:—

Evan David, London Hospital; George Frederick Hentch and Alfred Joseph Reeve Tyler, Charing-cross Hospital; Arthur Edw. Lyster, St. Bartholomew's Hospital.

**THE BRITISH MEDICAL BENEVOLENT FUND.**—A donation of £100 has been received by the Treasurer of this Fund from Dr. Beane of Melbourne.

**ST. THOMAS'S HOSPITAL MEDICAL SCHOOL.**—The Entrance Scholarships in Natural Science have been awarded as follows—viz., Scholarship of £100 to Mr. Horace Duncan; Scholarship of £60 to Mr. E. D. Shirtliff.

**QUADRUPLE BIRTH.**—The wife of a navvy at Pontypridd has been delivered of four fully developed living children at a birth. None of them, however, survived more than a few hours.

A STRONG opposition is being manifested against the erection of châteaux in the centre of the road at Ludgate-circus. A deputation has waited upon the Commissioners of Sewers, who lease the site to the company at the nominal rent of £10 for five years.

**SCURVY ON BOARD A PASSENGER SHIP.**—Lloyd's agent at Natal reports, under date Sept. 11th, that the *Bylgia* (Captain Anderson), from Hong Kong for Algoa Bay, with 127 Chinese passengers, put into Natal on Sept. 9th with scurvy on board. There had been twenty-four deaths.

At the quarterly meeting of the Directors of the Naval Medical Supplemental Fund, held on the 10th inst., Sir W. R. E. Smart, K.C.B., M.D., Inspector-General, in the chair, the sum of £75 was distributed among the several applicants.

**LONDON HOSPITAL MEDICAL COLLEGE.**—Mr. Hugh Smith has obtained the Entrance Science Scholarship of £60; Mr. E. Barclay Smith the Entrance Science Scholarship of £40; Mr. L. Raly the Buxton Scholarship of £30; and Mr. F. R. Ozzard the Buxton Scholarship of £20.

SEVERAL milk-sellers in Manchester have been amerced in heavy penalties for the adulteration and dilution of milk. One sample was described as consisting of forty parts of skim milk and sixty parts of water containing colouring matter!

**SOCIETY OF MEDICAL OFFICERS OF HEALTH.**—The first meeting of the session will be held at 1, Adam-street, Adelphi, on Friday, Oct. 20th, at 8 P.M., when the President, Dr. Tripe, will deliver an Inaugural Address on "Some of the relations between Meteorological Phenomena and Man."

**WEST KENT MEDICO-CHIRURGICAL SOCIETY.**—The following gentlemen have been elected office-bearers for the session 1882-83:—President: Mr. G. H. Cable. Vice-Presidents: Dr. A. Forsyth, Mr. J. Marshall. Council: Mr. A. L. Bowen, Mr. J. E. Burroughs, Dr. F. C. Fisher, Mr. J. Hammersley, Mr. C. H. Hartt, Mr. F. Moon, and Mr. J. P. Purvis. Treasurer: Dr. P. Purvis. Secretary: Mr. H. W. Roberts. Librarian: Dr. Saundry.

**PRESENTATIONS.**—Mr. David Richards having recently resigned his post as medical officer to the work-house and industrial schools, Brighton, the officers of the former establishment have presented him with two cases containing respectively a dozen silver bladed ivory-handled dessert knives and forks and half-a-dozen fish knives and forks to match. The presentation was accompanied by a letter expressive of the high respect and esteem in which Mr. Richards was held by the donors of the gift.—On Friday the 29th ult., Dr. Charles Brown, of Eastbourne, was presented by Mr. F. W. H. Cavendish on behalf of a number of patients with a handsome gold chronometer, chain, and locket, value seventy guineas. The watch bore the inscription "Presented to Dr. C. R. Brown by his patients, in token of their esteem. Eastbourne, 1882."

**SOIRÉE AT GUY'S HOSPITAL.**—At Guy's Hospital there was, on the 2nd inst., a brilliant conversazione, at which there was a larger attendance than on any previous occasion. The decorations supplied by Messrs. Gillow were extremely handsome, especially the central drawing-room, which was upholstered in various oriental materials, giving to the whole a most luxurious aspect. Owing to the kindness of Messrs. Siemens the electric light was employed in all those parts of the buildings and grounds used for conversazione purposes; it was peculiarly clear and steady, and worked the whole evening without any misadventure. The object of most of the scientific exhibits was to popularise Mr. Francis Galton's ideal anthropometric laboratory. Thus, at one table, visitors could have their acuteness of vision for form or colour tested, at another their hearing and tactile powers were examined, at another their blood was analysed, and lastly their personal equation was determined. One of the attractions of the evening was the telephone-room, fitted up by the United Telephone Company, in which it was possible to hear the music of "Patience" at the Savoy Theatre, and also to talk with people at the London Hospital. In one of the rooms a very good band played a capital selection of music. During the evening the Right Hon. Lord Justice Bowen, one of the governors of the hospital, distributed the prizes.

## Medical Appointments.

*Intimations for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning at the latest.*

**BENSON, ARTHUR H.,** M.B. Univ. Dub., L.R.C.S.I., has been appointed Medical Officer to the Dublin Throat and Ear Hospital, vice Bertram C. A. Windle, resigned.

**BROOK, WILLIAM FRED.,** M.R.C.S., L.S.A.Lond., has been appointed Medical Officer to the Fareham District and Workhouse of the Fareham Union, vice Barnard, resigned.

**BYRNE, W. S.,** M.B., M.Ch. T.C.D., has been appointed Surgeon-Superintendent to Prince Alfred Hospital, Sydney, New South Wales.

**CONNON, CHARLES JAMES, M.B.,** M.S. Aber., has been appointed Medical Officer for the Tenth District of the Hexham Union.

**CONRY, J. T. CROSBIE, L.F.P.S. Glas.,** L.K.Q.C.P.I., has been appointed Medical Superintendent to the new Infirmary at Hope, Salford.

**DUNNE, ALEXANDER, L.R.C.P. Ed.,** L.R.C.S.I., has been appointed Medical Officer to the Portaferry Dispensary District, vice Filson, deceased.

**EAGLES, WOODFIELD, M.R.C.S.,** L.S.A.Lond., has been appointed Surgeon-in-Ordinary to the Bucks General Infirmary, vice Ceely, resigned.

**FLINN, DAVID EDGAR, L.K.Q.C.P.I.,** L.R.C.S.I., & L.M., has been appointed Surgeon to St. Michael's Hospital, Kingstown, Dublin.

**FOSTER, PHILIP, M.D. St. And.,** M.R.C.S., has been appointed Honorary Physician to the Yorkshire Preparatory School for Deaf and Dumb Children, Leeds.

**GORDON, JOHN J.,** L.R.C.P. Ed., L.R.C.S. Ed., has been appointed Assistant Medical Officer to the Infirmary and Workhouse, Hackney Union.

**HEWETSON, H. BENDELACK, M.R.C.S.,** has been appointed Honorary Ophthalmic and Aural Surgeon to the Yorkshire Preparatory School for Deaf and Dumb Children, Leeds.

**JONES, ROBERT, M.B. Lond. &c.,** has been appointed Assistant Medical Officer at Colney Hatch Asylum (Female Department), vice Dr. Cobbold, appointed Medical Superintendent of Earlswood Asylum.

**LOYD, RICKARD W.,** M.R.C.S., has been appointed House-Surgeon to St. Peter's Hospital for Stone &c., Berners-street, W.

**MACDONNELL, MARK ANTHONY, M.D.,** M.Ch. Q.U.I., has been appointed Honorary Medical Officer to the South Dispensary, Liverpool, vice McGrath, resigned.

**MORGAN, E. RICE, M.R.C.S. &c.,** of Morriston, has been appointed Medical Officer to the Swansea Truants' Industrial School.

**O'CONNOR, FREDERICK, L.K.Q.C.P.I.,** L.R.C.S.I., has been reappointed Medical Officer of Health for the March Urban Sanitary District.

**REYNOLDS, ROBERT, M.R.C.S.,** L.S.A.Lond., has been reappointed Medical Officer for the Fourth District of the Halstead Union.

**ROUÉ, W. BARRETT, M.B.,** M.S. Dur., has been appointed an Examining Physician to the Scottish Imperial Life Assurance Company.

**St. GEORGE, GEORGE LOMBE, L.K.Q.C.P.I.,** L.R.C.S. Ed., has been appointed Surgeon to the County Antrim Infirmary, vice Thompson, deceased.

**STODDART, Mr. F. W.,** has been reappointed Public Analyst for the Borough of Bridgwater.

**STREET, ALFRED FRANCIS, M.A.,** M.B. Cantab., M.R.C.S., has been appointed Senior Resident Medical Officer to the Radcliffe Infirmary, Oxford, vice T. E. Hine, M.B., resigned.

## Births, Marriages, and Deaths.

### BIRTHS.

**COLTART.**—On the 6th inst., at Ashbourne House, Epsom, the wife of William Wilson Coltart, L.R.C.P. Lond., M.R.C.S., of a daughter.

**CROSS.**—On the 5th inst., at Stanhope-terrace, N.W., the wife of John Cross, B.A., M.D. Cantab., of a son.

**DEAKIN.**—On the 6th ult., at Allahabad, N.W.P., India, the wife of Surgeon C. W. Shirley Deakin, F.R.C.S. Eng., Junior Civil Surgeon, of a son.

**GOULD.**—On the 7th inst., at Queen Anne-street, Cavendish-square, the wife of A. Pearce Gould, F.R.C.S. Eng., of a daughter.

**LEONARD.**—On the 7th inst., at Camden-road, the wife of H. Leonard, M.B., of a son.

**SPENCE.**—On the 6th inst., at St. Ninians, Burntisland, Fife, the wife of Robert Spence, M.B., of a son.

**THATCHER.**—At Albany-street, Edinburgh, the wife of Charles H. Thatcher, F.R.C.S.E., of a daughter.

**WATHEN.**—On the 7th inst., at Coburg Villa, Richmond-hill, Clifton, the wife of John Hancock Wathen, L.R.C.P.E., of a daughter.

### MARRIAGES.

**HARRIS—CHALLINOR.**—On the 3rd inst., at St. Edward's Church, Leek, Staffordshire, James Penn Harris, F.R.C.S., of Liverpool, to Sarah Rosamond, daughter of the late Charles Challinor, Esq., of Liverpool.

**HAWARD—WALKER.**—On the 30th August, at the Parish Church, Knightwick, Edwin Haward, M.D. Ed., M.R.C.P. Lond., F.R.C.S.E., of Harley-street, Cavendish-square, W., to Mary, eldest daughter of the late John Smith Walker, Esq., of Knightwick Manor, Worcester-shire.

**HOCKIN—CLOW.**—On the 3rd inst., at St. Mark's, Hamilton-terrace, G. Treverno Hockin, M.R.C.S., L.R.C.P., fourth son of John Hockin, of Amersham House, Beckenham, to Cordelia Fanny, fifth daughter of the late Leonard Clow and Mrs. Clow, of Upper Hamilton-terrace.

**JOHNSTON—MEDCALF.**—On the 5th inst., at Leven, Augustus Johnston, M.B. T.C.D., M.R.C.S., of Gale House, Ambleside, to Judith Anne, younger daughter of the late W. Medcalf, of Broughton House, Newton-in-Cartmel.

**LOYD—HERMAN.**—On the 4th inst., at St. Peter's Church, Tiverton, Devon, James Hellings Lloyd, M.R.C.S.E., L.R.C.P. Ed., of Col-lumpton, Devon, youngest son of the late Rev. J. D. Lloyd, Rector of Clare Portion, Tiverton, to Marian (Alinnie) Armytage, only child of the late M. Herman, Esq., of Bath.

**NIND—HARVEY.**—On the 3rd inst., at St. Mary's Church, Vernon Pitt, second son of the late Philip Pitt Nind, M.R.C.S., of Torquay, to Jane (Jeanie), eldest daughter of John F. Harvey, Esq., of Earham, St. Mary's Church.

**REID—TURNBULL.**—On the 4th inst., at Friar's Bank, Dunbar, by the Rev. Robt. Buchanan, James Reid, M.B., of St. Helen's, Lancashire, to Susan, younger daughter of the late John Turnbull, M.D., of Dunbar.

**SAUNDERS—BARNES.**—On the 11th inst., at St. Mary's Cathedral, Edinburgh, by the Rev. Fitzroy Kelly Lloyd, Incumbent of St. John's, Pittenweem, Frederick Anastasius Saunders, L.R.C.P.E., L.R.C.S.E., to Mary Emily Louisa, only daughter of the late Captain Edmund Charles Barnes, H.M. late St. Helena Regiment.

**SCATLIFE—FRIEND.**—On the 4th inst., at Clermont Congregational Church, Preston-park, Brighton, Arthur W. Scatliffe, M.D., of Margate, to Lille, third daughter of Daniel Friend, Esq., of Stoneleigh, Preston-park, Brighton.

**WOODS—PITTAR.**—On the 4th inst., at St. Peter's, Brighton, Thomas Arthur Woods, B.A., M.B., L.R.C.S.I., L.M., of Douglas, Isle of Man, to Elizabeth (Bessie) Marmion, daughter of Thomas John Pittar, Esq., of St. George's-terrace, Brighton.

### DEATHS.

**RISDON.**—On the 6th inst., at the house of his sisters, Blideford, North Devon, Robert Risdon, M.R.C.S., late of James-street, Buckingham-gate, aged 58.

**SCOTCHBURN.**—On the 6th inst., at Great Driffield, Alfred Scotchburn, M.R.C.S., aged 55.

**SETH.**—On the 5th inst., at Tisbury-road, West Brighton, Owen Sath, F.F.P.S. Glas., Assistant-Surgeon to the 1st Surrey Artillery Volunteers, son of the late C. G. Sath, Esq., of Calcutta.

**TURRELL.**—On the 4th inst., at Windsor, Samuel Turrell, M.D. Edin., aged 60.

*N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

## METEOROLOGICAL READINGS.

(Taken daily at 5.30 a.m. by Steward's Instruments.)

## Notes, Short Comments, and Answers to Correspondents.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*All communications relating to the editorial business of the journal must be addressed "To the Editor."*

*Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.*

*Lectures, original articles, and reports should be written on one side only of the paper.*

*We cannot prescribe, or recommend practitioners.*

*Local papers containing reports or news-paragraphs should be marked.*

*Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."*

## THE ABUSE OF "OLD" DIRECTORIES, &amp;c.

In common with the members of other professions, medical men are insulted, and not unfrequently to some extent defamed, by the insolence of advertising tradesmen who, not content with misdirecting their multitudinous circulars by the use or abuse of "old" Directories, have the effrontery to address their missives to "Mrs. —," assuming that the practitioner must needs have a wife! If the commercial community could be convinced of its reckless folly in this matter of circularising, much money which is now wasted would be saved. The use of the old Directories is a great nuisance. We have quite recently heard of instances in which urgent letters requesting consultations have been directed to old addresses which have been wrong for three or four years at least. Better have no Directory than an old one, and better not send out circulars at all than address them to wives who have no existence.

*Tyro.*—Such an arrangement is not very satisfactory. It is not an open one, and involves something like a partnership with a druggist.

## DEATH CERTIFICATES.

To the Editor of THE LANCET.

SIR,—The following is a reply to my inquiry as to what constitutes attendance, and also what course a doctor must adopt in those numerous cases in which one visit only is made before death. You will notice that the registrar's ruling and that of a magistrate do not coincide, and a doctor is in an awkward predicament between the two.

I am, Sir, yours faithfully,

E. H. ROE.

The Poplars, Patricroft, Oct. 10th, 1882.

"General Register Office, Somerset House,  
London, W.C., Oct. 9th, 1882.

"Sir,—I am directed by the Registrar-General to acknowledge the receipt of your letter of the 8th inst., and to state that the Registration Act of 1874 (section 20) provides that, 'In case of the death of any person who has been attended during his last illness by a registered medical practitioner, that practitioner shall sign and give to some person required by this Act to give information concerning the death a certificate stating to the best of his knowledge and belief the cause of death.'

"It is impossible, under the varying circumstances attending medical treatment, for the Registrar-General to express any opinion as to whether one visit before death is or is not sufficient to warrant a medical man granting a certificate of the cause of death. The medical attendant is the best judge in such a matter; the Act only insists that he shall have been in attendance during the last illness.

"I have the honour to be, Sir, your obedient servant,

"WILLIAM CLODE, Secretary.

"To Edwin H. Roe, Esq., The Poplars, Patricroft."

## AN ALARMING POLICE ECONOMY.

It has transpired, and should be generally known to the public, that, with a view to reduce the police-rates, instructions have been issued to refrain from calling in a medical man to the aid of the "drunk or dying" at police stations unless the inspector on duty declares such a step necessary. The effect of this restriction has been, during the last year, to place the discrimination between the effects of drink and disease in the hands of policemen, who are supposed to have acquired some special knowledge and new power of diagnosis in the course of a brief instruction by the St. John Ambulance Society.

## "FEEDING LUNATICS."

To the Editor of THE LANCET.

SIR,—I am pleased to observe from your annotation of the 7th inst. that we do not, after all, differ very widely on this subject; you admit two points for which I argued—viz., that forcible feeding is necessary, and that "there are cases in which it is necessary to use the tube." You hold "that it is because the task of inducing lunatics to feed naturally is left to attendants the need for forcible feeding arises." I practically stated in my last letter that this task should be carried out under medical supervision, and not unfrequently actually undertaken by the doctor himself.

I think with you that "no medical man could possibly stand by and see a patient die of starvation rather than use the tube;" but I believe that the result of the unwillingness of some medical men to use the tube, if it can possibly be avoided, is that the operation is sometimes deferred too long, and that thus the opportunity of saving life is occasionally lost, just as it may be in certain cases by deferring a tracheotomy or a herniotomy. The patient is sometimes only fed with the tube when his vital powers have sunk so low that they cannot recover themselves. The death in such a case is rightly certified as being due to "exhaustion from mania" or "exhaustion from melancholia," as the case may be; but the patient might possibly have withstood the exhausting effects of his disease if he had been earlier supplied, by means of the tube, with the large amount of nutriment which the system requires under such conditions. It is probable that the patient has been diligently plied with food administered with the spoon, or by some other method of feeding; but in very bad cases it may happen that the result of an hour's continued effort is that the patient has only swallowed an ounce or two of liquid, whereas with the tube a pint or more of fluid food may always be administered in a few minutes. The latter method is far less exhausting to the patient, and there is no doubt about the food reaching the stomach.

It is often a most difficult point to decide when the tube should be used; no two cases are precisely alike, and there is frequently room for a difference of opinion on the subject. It is possible that in some asylums the tube is, as you believe, too freely used; but I feel very strongly that there is, on the other hand, a great and real danger of deferring its use until the patient is too exhausted to benefit by it. If, however, medical men do err in this matter, I quite agree with you that they do so "with the most earnest desire to benefit their patients."

The full discussion of this subject is probably more suited to a journal whose pages are devoted specially to subjects connected with the care and treatment of the insane; but since you raised the question in your columns, it seemed to me only right that your readers should have the opportunity of hearing both sides of the question.

I am, Sir, your obedient servant,

Earlswood Asylum, Oct. 9th, 1882.

CHAS. S. W. COBOLD.

*Mr. J. Thomas.*—There is some unaccountable delay in the issue of this report to the public, but it can be obtained from Messrs. King, Parliamentary Booksellers, King-street, Westminster, S.W.

*Dr. J. H. Bell.*—Thanks.*Dr. Pocock's* paper will appear in an early number.*Wm. Powell, M.B.,* has forgotten to enclose his address.

## "INTRA-VENOUS INJECTION OF FLUID IN SEVERE HÆMORRHAGE."

To the Editor of THE LANCET.

SIR,—In reply to your correspondent, Dr. Philip Foster, of Leeds, permit me to point out that for intra-venous medication, absolute alcohol is preferable to brandy, as being purer, the latter agent containing anæsthetic ether and volatile oil, together with colouring and other matters derived from the cask, in which it has been kept, besides the frequent addition of burnt sugar. The employment of salt instead of a saline powder of the formula advocated by me (THE LANCET, Sept. 16th, 1882, p. 437) might answer the purpose, but I submit it is preferable to use a powder which imitates approximately the salts of the blood.

The advantages of my syphon over the common obstetric syringe are—first, the almost impossibility of admitting air; and, secondly, the greater uniformity with which the medicated fluid can be introduced into the venous system by it. Moreover, the idea of using for the operation of intra-venous injection an instrument which a few hours previously may have been employed for the administration of a nutrient or purgative enema for the purpose of cleansing the uterine cavity in a case of pyæmia by means of a carbolic douche, or as a method of arresting post-partum hæmorrhage by the injection of perchloride of iron, is not to me a pleasant one.—I am, Sir, yours faithfully,

CHARLES EGBERTON JENNINGS.

London Hospital, E., Oct. 6th, 1882.

## THE TREATMENT OF THE WOUNDED ON THE "MALABAR."

THE following important letter, testifying to the humane treatment received by the sick and wounded on board the *Malabar*, appears in the *Pall Mall Gazette* of Tuesday last:—

To the Editor of the *Pall Mall Gazette*.

SIR,—A paragraph in a local paper has just come under my notice, quoting a correspondent of the *Pall Mall Gazette*, who "calls attention to the shameful manner in which the wounded were neglected on board the *Malabar* during their passage home." He is further said to have stated "that some of the men did not have their wounds dressed from the time they left Alexandria till their arrival at Portsmouth." What opportunities your correspondent may have had of verifying the terrible accusations he brings against the surgeons entrusted with the care of the wounded on board the *Malabar* I know not; I can only say that as a passenger in that ship I spent on an average an hour daily with the sick and wounded on board, and can unhesitatingly assert that within my experience I have rarely seen more assiduous care bestowed by the doctors on those under their charge than was the case on board the *Malabar*. Going about as I did as far as possible as the men's friend, and being in no way connected with the army, I naturally heard complaints from time to time from the men's lips. Many men regretted leaving the superior comforts of the hospital ship *Carthage*, mentioning especially the loving care with which they were nursed there by the lady nurses who have so nobly volunteered their services in a burning Egyptian climate; some, too, complained that they should have liked more to eat—low diet, is, I believe, necessary where there is any risk of inflammation; and many were anxiously looking forward to the change from the necessarily somewhat crowded quarters on board to the airy wards of Netley Hospital. But I never heard one word of complaint against the doctors; while, on the other hand, I particularly remember one day, when telling the men that the doctor was rather sea-sick, their warm expressions of sympathy with him, saying, "He is so kind to us," &c. I hope, Sir, that by inserting this letter you will do your best to repair the cruel wrong that has been done to those in charge of the wounded. I shall be glad to give your correspondent any information I can on the subject. I enclose my card, but must sign myself,

A PASSENGER ON BOARD THE "MALABAR."

South Petherwyn, October 10th, 1892.

## "DRAIN-PIPES: A QUERY."

To the Editor of THE LANCET.

SIR,—In answer to the query of "M.D.," in your journal of Sept. 30th, as to the above, I should imagine the increased luxuriance of the grass was simply the result of thorough drainage and deep cultivation. When the drain is cut and the pipe laid in, the opening is filled up with the earth previously dug out. This is deep cultivation, and the pipe carrying off the superfluous water, the soil between the pipe and the surface being freed from water, would be of a slightly warmer temperature, and thus increase the growing powers of the soil; hence the luxuriant appearance. Let "M.D.," when the ground is covered with snow, watch the three drains, and he will possibly find, on a thaw setting in, that the snow will disappear along the line of drains sooner than on the adjoining ground, no doubt the result of a drier and somewhat warmer soil. I may mention that about forty years ago I superintended the cutting of over one hundred miles of drains.

I am, Sir, your obedient servant,

Oct. 2nd, 1892.

G. J.

To the Editor of THE LANCET.

SIR,—I have observed a similar appearance as your correspondent, "M.D.," and concluded that the increased luxuriance in the growth and deeper tint of the grass depended on the subsoil having been changed during the process of laying the drain-pipes; that portions which were previously deeply buried had been brought near to the surface, and had supplied a new pabulum to the roots of the grass.

I am, Sir, yours, &c.,

WM. KELLY, M.D.

Taunton, Oct. 5th, 1892.

Mr. Thos. Richardson.—The name of the Institution mentioned is not included in the "Medical Register and Directory of the United States."

V. J. is referred to a general announcement in another column.

## EXTRA FEES FOR INSTRUMENTAL LABOURS.

To the Editor of THE LANCET.

SIR,—With regard to the above, I should be glad to know whether it is the practice of Boards of Guardians to allow them to workhouse medical officers, for such I take Dr. Barnes to be.

A short time ago I was refused an extra fee in a case of that sort, and I wrote to the Local Government Board on the subject. The answer I received was that the regulation about extra fees only applied to district medical officers; and the same rule, I take it, applies to the surgical fees for accidents and operations—at least the regulation seems to exclude the union medical officer altogether. Are medical officers of workhouses aware of this ruling, which certainly gives them no encouragement to undertake any operation requiring assistance and involving time and trouble? I could get no reason from the Local Government Board for any difference being made between district and union medical officers, and should be glad to know if in your opinion any sufficient one exists.—I am, Sir, faithfully yours,

Salop, Sept. 27th, 1892.

WORKHOUSE MEDICAL OFFICER.

## THE BANGOR EPIDEMIC.

WE have received a communication from the Clerk to the Bangor Local Board of Health denying the accuracy of certain statements which we felt it our duty to make with regard to such matters as the tardiness of the Board in taking the measures necessary to stay the spread of the enteric fever outbreak. Owing to the tone and character of the communication we defer inserting it until our next issue, when we hope the official report on the outbreak will have been issued, and when, we feel convinced, every statement we have made will be fully confirmed.

A Friend of the I.W.D.—Our correspondent's strongly worded letter is based upon a mere rumour, the correctness of which is, to say the least, doubtful.

W. Easby, M.D., is thanked, but we must decline to notice the man or his effusions.

## THE USE OF TOBACCO.

To the Editor of THE LANCET.

SIR,—In reply to your query of last week, allow me to give my experience. It is only the observation of myself, and so not of much import; but if each or many members of our profession will send their experiences, we may be able to draw certain conclusions.

I started smoking about the age of eighteen, and did so that I might be like my fellow-students. My first cigar made me very ill. I was sick, purged, and very dizzy, had gripping pains in the abdomen, violent palpitation, and came out in hot and cold sweats. The smell of tobacco after that was distasteful for a time, but being determined to become a smoker, I tried again and again, until I could smoke without great discomfort. I had many minor attacks of vertigo during my time of learning. I smoked first after tea only, then whilst tea was making, then after dinner, and so on until I could smoke any time of the day. I also found as the time for smoking came round I wanted to smoke; I had a craving which nothing but tobacco would satisfy. I continued smoking for about four years, during which time I had many minor complaints which I have lost since leaving it off. It often brought on palpitation, which I never have now. I am myopic from early study, but a pipe of tobacco would sometimes make me more so. In other words, a smoke would entirely destroy the effect of my glasses, and when I had them on after a smoke I could only see as far as when I had them off on an ordinary occasion. Again, at night time I had cramp in the muscles of the calf and of the sole of the foot. If I left off smoking for a few days I noticed this became less, and when I left it off entirely the cramp went also, and I have never had it since. If I smoked more than usual the cramp extended to the muscles of the thigh and back of the hand. On one occasion, after a heavy smoke, it seized the muscles of the jaw whilst I was yawning, and kept my mouth open; I had to shut it forcibly. I was also troubled with subeultus tendinum, or a sudden twitching of the muscles of the lower extremities. This even would spread to the whole body, and when asleep or falling asleep I was often awakened by a sudden twitch of the whole body, as if an electric shock had been given me suddenly. This I have never had since I left off smoking. The cramp is often seen after severe purging or vomiting, and the subeultus in children when they are feverish. I expect both are due to some irritation of the solar plexus; some physiologist will no doubt set me right. After a smoke my handwriting became very strange; the letters were not firmly made, but wavy, like the handwriting of an aged or infirm person.

Others I find are sometimes subject to the same sensations as I was. To many it is the cause of sore throat and indigestion. One case attracted my notice, which I think is almost unique. A youth in a saw-mill got many small cuts about his hands, and they would not heal. He consulted me about them. I tried protective measures and tonics with no result. These cuts continued for some months, and would not heal. One time he was very busy and ran out of tobacco; he did not smoke for three days, and to his surprise he found his wounds healing. He stopped smoking, and in nine days they were perfectly healed. He then started smoking again, got some more cuts, and they would not heal; so he left off smoking, and they rapidly healed. He then came to the conclusion that it was not good for him to smoke, and he has left it off. Now his cuts heal the same as those of others. Smoking, again, is often a mannerism, the same as scratching the head or biting the nails, of a more harmful kind though.—I remain, Sir, yours truly,

T. R. ALLINSON, L.R.C.P. Ed., &c.

Kingsland-road, E., Oct. 3rd, 1892.

J. V. R. C.—We regret that we cannot afford the space for our correspondent's letter. We entertain doubts of the advantage which in his opinion would be gained by the adoption of his suggestions.

A Student will doubtless gather from the Students' Number the information he desires.

## A QUERY.

To the Editor of THE LANCET.

SIR,—Can any of your readers throw light upon a case where there is a discharge of printer's ink from the great toe near the nail, the lesser toes being inflamed at the top on the palmar aspect. The lesser toes of the other foot are also affected—red, and with a severe pricking pain. It is thought to be an exceptional case. Is it so? How is this discharge produced? There is no fetor.—I am, Sir, yours truly,

Appledore, North Devon, Oct. 8th, 1892.

F. PRATT, M.D.

## MEDICAL PORTRAITS.

WE cordially agree with our correspondent, *Chiaroscuro*, that it is highly improper that any member of the medical profession should suffer his portrait and biography to appear in what is practically a trade circular, more especially if "before going to press a proof of the biographical sketch be submitted" to the subject of the notice "for revision."

*M. D. Kelly*.—It is impossible to answer the question put by our correspondent, as the amount of knowledge acquired depends more upon the recipient than the channel through which it is conveyed. The following are the books officially recommended for study:—*Animal Kingdom*, by W. S. Dallas; *Outlines of the Structure and Functions of the Animal Kingdom*, by Rymer Jones, or *Cours Élémentaire d'Histoire Naturelle*, par Milne-Edwards; *Lindley's School Botany*; *Lindley's Medical and Economic Botany*; *Henfrey's Elementary Course of Botany*; *Elements of Natural Philosophy*, by Golding-Bird and C. Brooks; *Physical Geography*, by Mrs. Somerville.

*Dr. James Wilson*.—We are not aware of any such appointments.

*Mr. C. J. E. Walkey*.—We are compelled to decline the offer.

## "A DISAGREEABLE DUTY."

To the Editor of THE LANCET.

SIR,—My complaint of a want of courtesy on the part of a house-surgeon at the London Hospital has evoked a reply from that official, which to me appears to have been written more as an insult than to refute the charge.

In his efforts at retaliation, Mr. Hingston displays a looseness of assertion which may one day lead him into some difficulty. Without the slightest foundation except his own ignorance or carelessness in reading the Register and Directory, he has thought fit to publicly assert that I am not what I represent myself to be.

Amongst other inaccuracies, he says, "Mr. Wise is not registered, and his name does not appear in the Medical Directory; and though he signs himself 'M.D.,' he can scarcely expect to be considered a brother professional."

The wickedness of publishing such a libel on a professional man in the leading medical journal is inexcusable, and not to be countenanced for one instant. I must call upon Mr. Hingston for an immediate and unequivocal apology for the unwarrantable statement he has thought fit to make. Should this not be forthcoming in your next issue, I shall be under the necessity of taking further steps in this matter.

I am, Sir, your obedient servant,

Shoreditch, Oct. 10th, 1882.

ALFRED WISE, M.D.

*Mr. Laffan (Cashel)*.—We think the complaint should be referred to the conductors of the paper in which the offending article appeared. It would be against our rule to interfere in the matter under the circumstances described.

*Mr. Hargreaves (Armley)*.—We have no recollection of the communication.

*Justice* should read THE LANCET before he complains of omissions. He will find the opinion given on page 647.

## "USE OF APOMORPHIA."

To the Editor of THE LANCET.

SIR,—In answer to your correspondent, "M.B.," I beg to quote as follows from a "Commentary on the B.P.," by Dr. Walter Smith, of Dublin University:—"Its most conspicuous effect is as an emetic of extraordinary power and rapidity; one-thirtieth to one-tenth of a grain of the hydrochlorate subcutaneously, or one-tenth to one-fourth by the mouth, will induce vomiting in a few minutes, painlessly and without subsequent nausea or prostration. Apomorphia offers special advantage in dealing with refractory children, insane people, or with adults in some cases of poisoning when coma, delirium, or spasm prevents the oral administration of emetics."

I am, Sir, yours, &c.,

Oct. 2nd, 1882.

T. C. D.

*M.A., M.B.*—We agree with our correspondent that clinical details should be omitted from accounts of illness that appear in the lay press.

*A Youngster and F.R.C.S.*—Nothing could be gained by continuing the discussion. The hint given may have some effect.

*C. Rubens*.—We are unable to discern any particular merit in the appliance.

*Aries* has not enclosed his card.

## "TREATMENT OF EPILEPSY."

To the Editor of THE LANCET.

SIR,—I am much indebted to Dr. Oscar Jennings and Mr. Wrixon for their letters in THE LANCET of Saturday last. Might I ask Dr. Jennings to kindly say into how many doses per diem the four tablespoonfuls of the bromide solution should be divided, and if one of the pills should be taken twice a day, or two of them once only.

I am, Sir, yours obediently,

Oct. 9th, 1882.

ALPHA.

*S. J. C.*—Our correspondent's former letter must have been mislaid. The case is a painful one to both parents and practitioner. We think it is a case in which a certificate of the facts should have satisfied the registrar or the coroner without the formality of an inquest. There is no blame attaching to a practitioner who does not feel able to certify the cause of a death. But in such cases as the present the best course is to write a statement of the facts as far as they are known, and leave the responsibility of an investigation to the registrar. We do not doubt that the gratitude of the parents for attentive and successful treatment will survive other feelings.

*Dr. P. O'Connell (Sioux City, Iowa, U.S.A.)*.—The Prix Saint-Paul, consisting of a sum of 25,000*fr.*, will be given to anyone who first finds a cure for diphtheria which shall be recognised by the Academy as certain (*efficace et souverain*). The interest of this sum may be awarded to any whose researches on this subject may appear worthy of encouragement. Written memoirs must be either in French or Latin, but any printed works may be sent in competition. For the year 1883 essays are to be deposited at the Academy of Medicine before the 1st of July.

## THE CONTAGIOUS DISEASES ACTS.

To the Editor of THE LANCET.

SIR,—Having seen the working of the Contagious Diseases Acts in different ports, I must differ from the opinion expressed in your article of Sept. 30th and your correspondent last week. The only Contagious Diseases Act that could be worked in a city or civil town would be that of 1864, improved and carried out by a health board, independent of municipal police, in a similar manner to the mode adopted for scarlet fever and small-pox. Opposition is always shown to police, when none is given to health officers. As a commencement, medical treatment and hospital support might be made from public funds for those suffering and voluntarily presenting themselves, who are more anxious for cure than is generally stated, in larger numbers, if not annoyed by the addresses of a certain class of visitors.

I am, Sir, yours obediently, H. HARKAN,  
Craven-street, Strand, Oct. 9th, 1882. Deputy Inspector-Gen., R.N.

*G. P.* should inscribe his qualifications on his plate. The object of putting the initials or the name on a prescription is not to procure practice, but to supply a means of reference and a guarantee of good faith in the prescription.

*Dr. J. Ashburton Thompson*.—The official list has not yet reached us, but our rule is to print each pass-list as we receive it from the examining body.

*Justice*.—Undoubtedly C had a right to apply for the vacated appointment; but unless B's retirement was a matter of notoriety, he was not justified in canvassing before the resignation.

## "THE USE OF THE FORCEPS IN MIDWIFERY."

To the Editor of THE LANCET.

SIR,—I am not at all addicted to the use of instruments where they can possibly be avoided; yet I find, on referring to my obstetric list, that of the last 400 cases attended by me, the forceps were used 12 times—i.e., 8 times in primiparæ and 4 times in multiparæ, or an average of about 1 in 33. I think it likely that half these cases might have been terminated without the use of forceps had I felt myself justified in exposing the poor women to several hours' further unnecessary agony; but I may say that I make it a rule of practice not to wait more than three hours when there is no advance in the second stage of labour.

I disapprove as much as anyone of meddling midwifery, and can scarcely believe that in a run of several hundred consecutive cases it can ever be necessary or desirable to employ the forceps in so many cases as 1 in 8—the proportion in which they are said to have been employed by the late Master of the Rotunda.

I am, Sir, yours faithfully,

Wood Green, Oct. 9th, 1882.

B. A. RUGG.

SEVERAL letters on the subject of the Degrees of the Queen's University in Ireland, as well as other communications, are unavoidably left over. We shall try to find room for them next week.

*Mr. Norris (Weston-super-Mare)*.—The announcement appeared in our issue of the 23rd ult.

*Mr. C. P. Heap*.—We cannot offer an opinion on the merits of the machine without having an opportunity of inspecting it.

## THE LATE MR. CLOVER.

To the Editor of THE LANCET.

SIR,—In your very just obituary notice of my old friend Mr. Clover, of October 7th, p. 597, will you allow me to add that he certainly was present at the operation you refer to, and to say that Mr. (now Dr.) W. Squire administered ether.—I am, Sir, your obedient servant,

WILLIAM SQUIRE, M.D., &c.

Orchard-street, Portman-square, W.,  
Oct. 9th, 1882.

## Clinical Lecture

ON A CASE OF

MEDULLARY SARCOMA OF THE LIVER,  
RIGHT LUNG, AND HEART.

By DAVID DRUMMOND, M.A., M.D., T.C.D.,

PHYSICIAN TO, AND JOINT LECTURER ON CLINICAL MEDICINE  
AT, THE NEWCASTLE-ON-TYNE INFIRMARY.

GENTLEMEN,—I take for my subject to-day the case of a patient whom you saw in the Bishop ward of the infirmary, and on whom you witnessed a necropsy a few days ago. He was a coal-miner, aged thirty-two, and of very intemperate habits. Ten weeks before admission, when in his usual health, he lay out all night in a drunken condition, exposed to rain and cold. The result of this exposure was an attack of shivering, followed by a "stitch" in his right side, and cough. He then sought advice, and was told he had "caught cold in his chest," for which he received medical treatment. Though ill, he continued to follow his employment, which he did for a fortnight subsequent to the initial attack, though evidently "against great odds," as the medical man, under whose care he afterwards came, wrote when he kindly supplied me with the early particulars of the case. He then was confined to bed; the pain in the right side became more severe; he complained also of pain in the abdomen (hypogastrium) and back; his cough increased; profuse perspirations occurred; and the expectoration, which previously was muco-purulent, became sanguinolent in character. About this time he suffered much from "what seemed most like diaphragmatic cramp." (I quote from his doctor's notes.) The bowels were irregular, generally costive, and his appetite was very bad. Three weeks before admission the result of physical examination was as follows: "The right chest was dull on percussion to the spine of the scapula; the respiratory sounds were feeble, and without vocal resonance; dulness in front extended up to the nipple, this continued over the liver two fingers' breadth below the ribs." All this time he was emaciating rapidly. The case was regarded as "fluid in the chest, probably pus, which depressed a congested liver," which undoubtedly was the most obvious construction to put upon the data at that stage of the case.

When brought to the infirmary the patient looked exceedingly ill; he was markedly wasted, and his face wore a most anxious expression. He was unable to lie on the left side or on the back on account of the pain across the abdomen and back, which was always much increased in severity when he assumed either of those positions; it was especially painful for him to lie on his left side. He also complained of "shoulder-tip" pain, right and left. His favourite posture was on his hands and knees, with his head buried in the pillow; but it was also a relief to lie on the right side. When he assumed the dorsal decubitus, with the abdomen exposed, a tumour at once became apparent, which was evidently the liver. The right lobe, the sharp edge of which could be distinctly felt, reached down to the crest of the ilium; the left extended down to one centimetre below the umbilicus, and completely across the abdomen. On the surface, the organ (on admission) felt comparatively smooth, and, although firm, not what is generally termed hard. At the extreme border of the right lobe an indistinct nodule or two could be felt; but handling the liver caused so much pain that this method of examination was not pushed beyond what was considered necessary to elicit the few points already referred to. There was no ascites, nor was he in the slightest degree jaundiced. A short "hacking" cough attracted our attention to his chest. The right thorax was one centimetre larger than the left; the ribs were slightly separated, and the interspaces somewhat flattened. The side expanded very imperfectly, being almost still on the deepest inspiration. On percussion, the side (right) was found to be absolutely dull posteriorly, conveying to the finger the sensation of marked resistance. Auscultation revealed the vocal and breath sounds to be notably diminished, such distant respiratory sounds as were present being evidently conducted from the opposite side. In front, also, the right chest was dull on percussion, the dulness extending across to the left parasternal line.

No. 3086

Here the stethoscope revealed nothing beyond abnormal silence, the feeble sounds which were audible being conducted from the heart and bronchial tubes. The left lung appeared to be normal, for beyond puerile breathing accompanied by a few rales, physical examination elicited nothing. The heart sounds were feeble, especially the first; there was no murmur. The apex beat was with great difficulty localised, but seemed to be in the left nipple line between the fifth and sixth ribs. The cardiac area of dulness was not accurately mapped out, merging as it did into the right lung dulness. The patient suffered considerably from dyspnoea. There were no signs of pressure upon the large thoracic vessels, neither oedema nor superficial veins. The expectoration was distinctly of two kinds—viz., muco-purulent, and like red currant jelly (bloody). The urine was scanty, but beyond being loaded with "vermillion" urates, it was normal, containing no albumen. Our patient's appetite was excessively bad, indeed, he had a great dread of swallowing food, either liquid or solid, as the slightest distension of the stomach enhanced the pain beyond endurance; consequently, the only sustenance he received had to be administered per rectum. The perspirations were very profuse, especially about the face, neck, chest, and hands, the skin of the abdomen being generally dry and harsh. The temperature was, as a rule, sub-normal, ranging between 96° and 98° F. The diagnosis, those of you who saw the case will remember, was made of malignant disease of the liver and right lung—most probably encephaloid cancer. The grounds on which such a conclusion was founded were, as far as the lung was concerned, dulness, markedly increased resistance (solidity), absence of vocal and breath sounds, the knowledge that the pleural cavity did not contain fluid—for the patient had been tapped in a special hospital before admission into the infirmary, a little blood alone being drawn off, according to his wife's account,—with the presence of disease in other organs (liver). And, as regards the liver, the last-named fact—i.e., extension of the disease,—rapid progress of the case, and the existence of a painful, somewhat nodular, enlargement. The medullary form of cancer was chosen because of the rapidity of the increase, scirrhus being generally much slower in its advancement.

A few days after his admission it was observed that the nodules on the surface of the liver were much better marked than when the patient was first seen, especially was this the case on the edge of the right lobe, where the tubera, as the nodules of new growth are sometimes called, were distinguishable. It could be made out with ease that the whole organ had increased in size within a few days, the left lobe extending down to two centimetres below the umbilicus; on its surface also, at that date, nodules could be felt which distinctly changed the character of the hitherto almost smooth left lobe. It was thought desirable to try, if possible, to make the diagnosis more certain by ascertaining the description of cells of which the apparently new growth was made up; consequently, to this end, the hypodermic syringe was used, following the practice which you know is constantly adopted in the wards of the Newcastle Infirmary. And here I would take the opportunity of impressing upon your attention the utility of employing the hypodermic needle as a routine act in medical diagnosis; by its use you will often be saved from grave errors. One well-known physician remarked to me, in conversation upon this subject, that he had used the hypodermic syringe constantly for the past two years, ever since he had made a serious error, which probably could only have been avoided by the possession of such evidence as the needle could have furnished. As the patient—the subject of the present case—was getting hypodermic injections of morphia to relieve pain, I endeavoured, as you will remember, to add as little as possible to his sufferings in pursuing the method of investigation of which I have just spoken; consequently, on one or two occasions, I administered the morphia immediately over the part of the liver I wished to puncture, and then, after a second or two had elapsed, I thrust the "needle" into the liver. By this means, without causing any pain, I was enabled to draw off a few drops of fluid resembling pus, or cancer juice. My object in injecting morphia before puncturing was to guard against the risk of causing pain by groping about with the point of the needle, should the site at first selected be not a suitable one. The cells drawn off in this way were of two descriptions—the most numerous resembled pus cells very closely, there being also a few somewhat larger, irregular-shaped, cells, some oval and others almost caudate with a single nucleus. It was

Q

thought then that in the juice from the liver we had discovered pus and cells usually found in the alveoli of medullary carcinoma; though this view was somewhat shaken, especially as regards the pus, when a subsequent puncture into a part of the liver not nodular furnished dark blood which contained a number of the same small round cells. Microscopical examination of the sputum, which as before stated, contained blood, yielded no information of importance. The liver rapidly became more distinctly nodular. The harassing cough, almost constant retching and hicough, severe pain, profuse perspirations, and inability to take food soon brought the patient exceedingly low, and he died ten days after admission, and eleven weeks from the commencement of the attack.

The post-mortem examination showed the body to be very markedly emaciated; there was no jaundice or anasarca. The cavities were free from fluid. The liver, which occupied nearly the whole of the abdominal cavity, weighed 9 lb.; it was adherent to the diaphragm, especially by the right lobe. The surface was studded with pale yellowish nodules, varying in size from a pin's head to a small orange, the larger of

Left auricle.

Lung.

which were umbilicated, a condition which you can see well yet. Though the specimens before you have been in spirit for some days these nodules are still quite soft, and when cut into, as, for example, when a section is made through the liver, a considerable quantity of "juice," evidently rich in cells, flows from the surface. The liver substance itself was exceedingly pale, but apparently comparatively little of it is free from the new growth. The right lung, which was adherent, is, as you see, completely solid, the greater portion of the consolidation being due to so-called "grey hepatisation;" but a large mass of new growth, similar to that found in the liver, the size of a small coconut, embraces the root of the lung, and extends into its substance and down to the base, apparently infiltrating the pleura and diaphragm. The left auricle is also affected by the same growth, the extension having probably occurred along the pulmonary veins, which are surrounded and slightly compressed, the capacity of the auricle being reduced considerably. The left lung was congested, but otherwise normal. The kidneys, spleen, and pancreas were unchanged, though the latter was surrounded by a mass of

Liver.

Isolated cells from liver.

diseased glands. The stomach presented no unusual appearances; in short, there was no other disease but that already described. Those of you who were present at the necropsy will recollect that the opinion was advanced, from the naked-eye appearances, that the disease was encephaloid cancer. From the three sections (microscopical) which I have prepared from the heart, lung, and liver, you will see that that opinion was only correct in a limited sense, for the true structure of the growth is evidently sarcomatous, being composed of cells which resemble the small round-celled sarcoma, but with extremely little basement substance; only here and there is it possible to discover any intercellular substance. The cells are not uniform, like the small round-celled sarcoma, but vary considerably in shape and size; at the same time they are all of one type, being from round to irregularly oval. They are also larger than the cells of the ordinary lympho-sarcoma; for example, when compared accurately with sections of glio-sarcoma and lympho-sarcoma (so called) the cells appeared nearly twice as large, though apparently not at all so large as the cells of the large round sarcoma.<sup>1</sup> In the section from the liver it will be noted that

the growth has in certain parts taken on the appearance of encephaloid carcinoma, the cells being isolated by alveoli made up of delicate connective tissue, at the same time the greater part of the growth in the liver resembles the lung growth, but in the lung or heart no such arrangement can be found. In Wagner's "General Pathology" (translation) you will find the statement made that "transitions to medullary cancer (from round-celled sarcoma) arise." Other authorities allude to the coexistence of these two forms of disease. To the minute structure of the growth before us, differing slightly as it does from the "round-celled" sarcoma, I have been unable to attach any other more accurately descriptive name than that of "medullary sarcoma." In its clinical history and microscopical appearances it approaches so closely to that of encephaloid cancer that it is impossible to distinguish the two. Had I made out the true character of the cells drawn off by the puncture from the liver it is possible the disease might have been more accurately diagnosed, but, using as I did a strange microscope with a low power, I mistook the round, and somewhat oval, cells for pus. I have said that the clinical features of this form of sarcoma resemble medullary cancer very closely; certain it is that the former at times is quite as malignant in its nature as the latter. Virchow remarks in his "Cellular Pathology" (Trans., second ed., p. 487) when speaking of sarcomata, "in many cases they occur throughout the whole body metastatically, to such an extent that scarcely any organ is spared by them." In the rapidity of the growth also is there a near resemblance; medullary cancer of the liver being generally of very short duration, a fatal termination occurring within a few months, or even weeks. Comparing my observations upon the case with those of the medical man who saw the case first, it would seem that in a period of about twenty days the liver extended from occupying a position "two fingers' breadth" below the ribs down to the crest of the ilium. Indeed, from what I have been able to gather both from the patient himself and from information kindly furnished by another medical man who saw him, and also taking into account his wife's version, the period during which the rapid growth took place must have been a very few days. I am inclined to view the growth in the liver as secondary to the lung, which in turn was secondary to the mediastinal glands and connective tissue. Primary growths of the malignant type being rare in either of these organs, especially before thirty-five or forty years of age. I am unable to advance any view as to the means by which this form of sarcoma might clinically be distinguished from encephaloid cancer unless it be by the recognition of the true nature of the cells drawn off by the hypodermic syringe. It is worthy of attention that, in spite of the manner in which the liver tissue was encroached upon and compressed by the new growth, there was no ascites. Effusion into the peritoneal cavity in cases of cancer of the liver does not occur, as a rule, as the result of venous obstruction in the liver, as in cirrhosis of the organ, but it generally depends upon a chronic peritonitis originating in the neighbourhood of the diseased liver. At the autopsy we found the peritoneum remarkably free from disease. Ascites has been found to occur in about half of the cases, and jaundice, perhaps about as frequently; this latter symptom may be said only to be present when a cancerous nodule compresses the bile-duct in the liver, or when the duct is encroached upon by enlarged glands in the portal fissure; it is generally supposed to be characteristic of the jaundice of hepatic cancer that it continues to the end, having once occurred. The diagnosis of cancer in the lung is generally a matter of difficulty, especially where there are scattered nodules, in which case there may only be very slight alteration in the percussion and respiratory sounds. However, as primary cancer of the lung is extremely rare, it will often be found to be accompanied by mediastinal growth, from which the pulmonary affection has sprung, when there will be dulness extending across the sternum, which will either be due to aneurism, fluid, or tumour-consolidation of the lung almost never causing dulness, which extends across to the opposite side. Such was the case in our patient, and as neither aneurism nor fluid could be entertained, it was consequently supposed that a mediastinal tumour existed, which with the physical signs, dulness and diminished vocal and breath sounds, viewed in the light thrown upon the case by the discovery of the liver disease, led to the diagnosis of cancer of the lung. The diminution in the vocal and breath sounds depended of course upon occlusion of the bronchial tubes.

<sup>1</sup> Grosszellige Rundzellensarcom, Rindfleisch, fourth edition, p. 106.

Had the air passed to the lung—consolidated (grey hepatization) as it was—the difficulty must have been much increased. It is not at all unusual to find the lung infiltrated with caseous matter, where the root is affected by cancer. I recently made a post-mortem upon a case of cancer (scirrhus) of the penis, where this condition was well-marked in the left lung, secondary scirrhus deposit having attacked the root of the lung, and also the kidneys. I know of no means of recognising cancer of the heart during life, though it often occurs when the new growth occupies the anterior mediastinum.

## PERFORATING ULCER OF THE FOOT AND PROGRESSIVE LOCOMOTOR ATAXIA.

By FREDERICK TREVES, F.R.C.S.,

ASSISTANT-SURGEON TO, AND SENIOR DEMONSTRATOR OF ANATOMY AT, THE LONDON HOSPITAL.

PROF. BALL and M. THIBIERGE, in a paper read before the recent International Medical Congress,<sup>1</sup> have endeavoured to show that there is a "direct connexion" between perforating ulcer of the foot and locomotor ataxia, and bring forward twelve cases to demonstrate that circumstance. They assert that the foot sore has a twofold association with the spinal ailment. It may be one of the earlier or premonitory symptoms of the cord disease, or, on the other hand, it may prove one of the late or terminal manifestations. Before remarking upon these important conclusions I may detail a case now under my care in the London Hospital that would appear to bear out the assertions just made.

The patient is a single woman, a cook, aged thirty-nine. There is nothing important to note in either her family or personal history. Five years ago she developed a suppurating bunion over the left great toe. In about eighteen months this healed, and gave no further trouble. Shortly after it healed—i.e., about three and a half years ago—a perforating ulcer appeared over the head of the metatarsal bone of the second toe. This was preceded by a painful corn, under which an abscess formed. The ulcer is said to have led down to bare bone. Under treatment at the Infirmary at Eastbourne the sore healed, but soon broke out again. It healed and reopened several times, and became at last so troublesome that the left foot was amputated (Chopart) at the Eastbourne Infirmary some eight months ago. After the healing of the stump, which is firm and substantial, she returned to her work, and her feet remained sound until six weeks ago. At this time she developed a perforating ulcer over the head of the metatarsal bone of the second toe of the right foot. It was preceded by a corn and an abscess, as was the sore on the left foot. Shortly after this a like ulcer appeared on the most prominent part of the stump of the left limb, appearing in like manner after a dense corn, beneath which suppurations had taken place.

She has now a circular callous ulcer surrounded by horny epidermis on both the right foot and the stump of the left foot in the situations indicated. The former leads to bare bone, the latter to a sinus three-quarters of an inch in depth. Seven weeks ago she began to stagger in her gait, and has since then fallen down several times when walking. She is now remarkably ataxic in her lower limbs, the upper extremities being sound in that respect. She cannot walk without assistance, nor can she stand when the eyes are shut. There is anaesthesia of both lower extremities, which is somewhat unequally distributed as to degree. There is absolute absence of tendon reflex in both limbs. The feet do not sweat in excess, nor has that feature at any time been observed. The pupils act during accommodation, but are absolutely inactive to light. Her vision is normal. She has no strabismus, and there is nothing especial to note in her fundus. She has had "lightning pains," but no gastric disturbances, no neuralgia, and no trouble with her sphincters. It will thus be seen that the original ulcer of the left foot made its appearance before any evidences of ataxia had developed, and if one could accept without reservation MM. Ball and Thibierge's assertions as to the relation of this ulcer to locomotor ataxia, it will

be obvious that the sore assumes a very remarkable importance in general medicine. Unfortunately MM. Ball and Thibierge's statements are not made without reservations. They are forced to recognise more than one form of perforating ulcer of the foot, and of the possible varieties they only assert that one form has part with the spinal malady. Their general conclusion as to the nature of the sore is that it is "a tropical disease of nervous origin," a conclusion closely in accord with that expressed by Messrs. Savory and Butlin in their admirable monograph,<sup>2</sup> wherein they assert that "the so-called ulcer is the result of pressure or violence to structures whose nutrition is impaired or whose vitality is defective from disease or degeneration of the supplying nerves." Now the many contributions that have of late years been made to the pathology of this foot affection would tend to claim for it the dignity of a special disease, and give to it a very pronounced clinical individuality. Thus the French authors above mentioned would place one form of the foot sore among the specific manifestations of locomotor ataxia, and from their paper one would gather that they consider its relation to the cord disease as close and as pronounced as are the relations of the affection known as Charcot's joint disease. Messrs. Savory and Butlin moreover, in the monograph referred to, are disposed to give the following clinical picture of perforating ulcer:—It is an affection more common in men; it attacks certain parts of the sole; it is commonly symmetrical; it is particularly associated with a certain amount of anaesthesia of the part, with sweatings of the foot and with certain peripheral nerve-changes. That foot sores are met with with these characteristics no one would dispute, but the grouping of these various characters so as to form one special disease may, I think, be a matter open to question. I have had under my care during the last few years three men with ulcers situate on the soles of the feet, that were symmetrical, that were preceded by suppurations beneath a corn, that led down to bare bone, and that long resisted treatment. In no one of these cases was there any anaesthesia of the part, nor any undue sweatings of the foot, nor any evidence of nerve affection of any kind. One man has been under observation at various times for two years, and is still free from any obvious trace of nerve disease, either central or peripheral. In these three individuals I imagine that the disease is solely and purely local—as purely local as a bed sore under the heel of a man confined to bed with a fractured femur. A corn forms; it presses like a foreign body upon the soft parts beneath; that pressure leads to suppurations; the pus moves deeply on towards the parts offering the least resistance, and by the time that it has found its way through the dense corn-tissue, it has probably in the other direction reached the bone. That any lesion of the nerves of the extremity would favour the development of such a local sore is obvious; just as a bed sore would be more likely to occur in a subject of paraplegia than in a patient bedridden with some other than a disease involving gross nerve change. In one of Messrs. Savory and Butlin's cases the patient appears to have suffered from some infantile affection of the nerves of the limb, and yet from a perusal of the paper one gathers that the symptoms of that nerve affection are included among the individual features of the sore that in time he developed upon his sole. I imagine that it would be more correct to ascribe the anaesthesia, the sweatings, and the microscopic changes in the nerve-trunks, to a central or peripheral nerve disease in relation to which the foot sore is a mere coincidence. To make use of these characters to complete the clinical individuality of the ulcer appears to be on a par with a description of a bed sore in paraplegia, as a sloughing ulcer associated with loss of power in the lower extremity, with anaesthesia, with certain visceral troubles, and with certain gross changes in the cord; all these features being maintained to be essential to the clinical individuality of the sore.

I would urge, therefore, that this "perforating ulcer" is a purely local affection, produced by purely local causes, which causes would act with increased vigour upon a part whose vitality is in any way impaired, but that that impairment is not of necessity dependent upon disease or degeneration of the supplying nerves. The relation of the malady, therefore, to locomotor ataxia would appear to be quite casual and unimportant, and of no more clinical value than would be a burn on the sole of an ataxic subject who

<sup>1</sup> Transactions, vol. II., p. 52. London, 1881.

<sup>2</sup> Transactions of the Medical and Chirurgical Society, vol. XLII., 1879, p. 373.

had unconsciously brought his foot in too close contact with fire.

In conclusion, exception may fairly be taken to the somewhat misleading name applied to this sore, since it does not appear to really perforate the foot in any ordinary case. Indeed the selection of its especial title appears to have been founded upon the same grounds that influenced Bottom in selecting a title for his vision, and of which he is reported to have said, "It shall be called Bottom's Dream, because it hath no bottom."

Gordon-square, W.C.

## REMARKS ON PROSTATORRHEA.

By D. CAMPBELL BLACK, M.D., L.R.C.S. EDIN., &c.,  
EXTRA-PHYSICIAN TO THE ROYAL INFIRMARY, GLASGOW; PHYSICIAN  
TO THE GLASGOW PUBLIC DISPENSARY.

(Concluded from p. 618.)

IN Case 2, given in the patient's own words, those of a highly intelligent gentleman, there were no spermatozoa in the discharge. The cause in this case seemed an aggravated varicocele, a condition which appeared to operate in a twofold manner, the one mechanical, the other physiological. In the former, the veins being large and valveless, a remosa is induced in the sexual apparatus—a condition of chronic passive congestion and irritation; in the latter pressure on the spermatic nerves causes peripheral reflex excitability by operating through the centre in the lumbar portion of the spinal cord, and the hypogastric and spermatic plexus of the sympathetic.

W—, aged thirty-four years, consulted me on March 6th, 1882. "Served in India for eleven and a half years continuously; returned on furlough in August of last year; have enjoyed exceedingly good health while there, though serving in most malarious tracts; have hardly felt the effects of malaria, but had a severe attack of cholera in November, 1877, from which, however, I recovered very rapidly. Habits have always been active; can stand more hard work and exposure than most men; have always been in the habit of taking a tolerable amount of liquor, but never to excess. Early in October, 1881, varicocele began to become troublesome, coming on about an hour after rising, and going off about noon. It was accompanied by the discharge of a few drops of gummy fluid after stools and micturition, generally in the latter case, on the first occasion after rising in the morning. This state of things continued until October 15th, when an emission took place. The varicocele then rapidly diminished, and the discharge from the urethra steadily improved. By the middle of November it had almost disappeared. Early in December it reappeared to a considerable extent without the slightest cause. I placed myself under medical treatment, and was told that my liver was out of order! After a little treatment to set this right a preparation of iron was given. The discharge improved, but erections began to give a good deal of trouble at night, and the varicocele reappeared. An emission took place on Dec. 20th, removing the annoyance from the varicocele, and followed, after a few hours, by the almost total disappearance of the discharge. About Dec. 27th the discharge reappeared gradually; also a little varicocele. The latter was entirely removed by an emission on Jan. 2nd. The discharge now began to show itself, usually a considerable time after micturition—three to five minutes. The discharge continued with slight variation up to about Jan. 17th, when it began to disappear. Varicocele became troublesome again about this time, and continued so regularly until Jan. 29th, when it was removed by an emission. Between Jan. 20th and 22nd the discharge was nothing more than a very irregular trace. On Jan. 28th and 29th it increased a little, but decreased again after an emission on the latter night to some extent. Another emission took place on Feb. 5th, followed by a slight increase. I was rather bilious at this time. I stopped the iron mixture, and by medical advice used medicine containing buchu, which appeared to have an excellent effect on the discharge, but disagreed with me otherwise. On Feb. 20th and the two following days there was a slight increase in the discharge, but it passed off again. From Feb. 23rd to 26th it was still wanting, but the penis was irritable, with a prickly sensation and a great tendency to erection. The irritation continued next day and the following one, on which the discharge reap-

peared at stool. On March 2nd the discharge assumed a yellowish appearance throughout the day and clear after stools. On March 3rd the yellow discharge before mentioned had given place to the usual one afterwards. The excessive tendency to erections at night has continued since about Dec. 15th. I think that the penis is in a state of erection more or less during the whole of my sleep. I have repeatedly to get up and thoroughly wake myself to get rid of it."

Such is the patient's own succinct and intelligent account of his condition. I saw him on March 6th of the present year. I found the left testicle greatly reduced, and the attendant veins large and tortuous. A good deal of genital irritation was complained of, and the urethral discharge was considerable. I had no hesitation in recognising, as cause and effect, the genital irritation, the discharge at stool (prostatorrhœa), and, doubtless, the involuntary emissions during sleep to some extent. It is particularly noteworthy that seminal emission was followed invariably by a diminution of the varicocele and of the urethral discharge; and, under all the circumstances, I felt justified in recommending an operation for the radical cure of the varicocele, administering at the same time the bromides of camphor and iron, which quickly diminished the troublesome genital irritation complained of. As operative interference had been discountenanced by the patient's London attendant, I requested that he should take further advice, and Dr. Alexander Patterson agreeing with me as to the expediency of the contemplated operation, I had recourse to it on March 17th, adopting the method of occluding the veins by subcutaneous wire loop, which I had previously found to answer well in similar cases. After eighteen days the wires were removed, and the veins operated on seemed permanently obliterated. On April 27th the patient wrote: "I begin to notice a considerable general improvement in its (the testicle's) size and consistence. The discharge has entirely ceased." Subsequent communications were correspondingly encouraging, and I had independent testimony to the efficacy of the operation through the courtesy of Mr. Bryant. On September 13th, 1882, the patient writes: "The varicocele gives no trouble even after prolonged exertion, walking or rowing; and my general health has improved greatly. . . . The left testicle has not increased much in size since I last wrote to you, but has grown much firmer. I should say its cubical capacity must be three or four times greater than before the operation. The whole mass, veins and testicle, is about the size of the other testicle now."

CASE 3 differs entirely from the foregoing, the cause being, I believe, injury to the spinal cord at a comparatively remote period. Besides, the discharge from the urethra contained spermatozoa and prostatic tube casts.<sup>1</sup> (Fig. 3.)

J. M—, aged thirty-two, consulted me on Nov. 2nd, 1881. There was no history of masturbation; he very moderately indulged in sexual intercourse. Twelve years ago he had gonorrhœa, which lasted a few months. About this time the patient fell into a ship's hold, alighting on his back on a prominent object, and also upon the occiput. He remained unconscious for about half an hour, and his spine was considerably affected. Subsequent to this period, particularly after lying on his back, on awakening, the patient noticed that his linen bore the marks of seminal emission. Emissions occurred unconsciously to the extent of twice or thrice a week. Simultaneously, and down to the present time, since receipt of the injury, more or less slimy, tenacious matter escaped from the urethra at stool. Six years before this the left testicle was injured by the falling of a box upon it. Inflammation and much swelling ensued, which, however, ultimately entirely disappeared. The slightest excitement, such as travelling on an omnibus, &c., causes irritation of the injured testicle. The parts are quite normal. No spermatozoa were found in the specimen of slimy matter passed from the urethra on first examination; but on Feb. 2nd abundant spermatozoa were found, as represented in Figs. 2 and 3 subjoined. On passing an instrument marked tenderness was found to exist in the prostatic region. To have bromide of potassium, combined with tincture of belladonna and buchu. This medicine very much moderated the seminal emissions. A large instrument was passed twice weekly.

April 17th, 1882: Still some discharge from the urethra at stool, but containing few spermatozoa. More or less swell-

<sup>1</sup> Compare with Mr. Solly's case of Spermatorrhœa from Spinal Injury, page 101, "On the Functional Diseases of the Urinary and Reproductive Organs." (Black.)

ing of the prostate only affording passage to a small instrument. On a subsequent visit I found that the spermatozoa had entirely disappeared, and that the amount of discharge was greatly diminished. As I have not seen the patient quite recently, I am unable to say whether he is completely cured, while, in my opinion, his progress towards recovery was such as to warrant the belief that he is. It should have been mentioned that this patient had been under medical treatment for this affection prior to his consulting me, and that he felt positive, as his appearance seemed to indicate, that his bodily vigour was undermined by the persistence of the discharge.

In Case 4 the history is somewhat different.<sup>2</sup> W. H.—,

FIG. 2.

aged twenty-nine, consulted me on the 7th October, 1881. Since the age of sixteen until within a few months he had been addicted to the habit of masturbation. Between the years of sixteen and nineteen he severely taxed his sexual system in this manner. His present complaint is that no matter how prolonged sexual intercourse may be there is no seminal emission. There is a slight orgasm and a mere oozing of slimy matter from the urethra. Slimy matter escapes from the urethra at stool, and patient has nocturnal emissions twice or thrice weekly. With the exception of a varicose condition of the right testicle, the sexual organs present externally no peculiarity. An examination of the urethra reveals prostatic hyperæsthesia. As an operation

FIG. 3.

for the varicocele could not be conveniently submitted to, the patient was advised to have a No. 10 metallic catheter passed twice weekly, and to have iron and strychnine, with bromide of iron, and watery extract of ergot internally. The subjoined diagram represents the nature of the urethral discharge.

On February 1st, 1882, the patient writes: "I have followed your advice by using the No. 10 catheter twice weekly, and with the result that the nocturnal emissions have ceased to trouble me; but the emissions at stool are

<sup>2</sup> Dr. S. W. Gross describes a case very similar to this at p. 125 of his book.

persistent and copious. No matter what the condition of the bowels may be, the emission takes place every time without exception." I have not heard from this patient since, and am thus unable to say what his present condition may be.

Case 5 is typical of a large number of cases of prostatic and sexual debility. August 18th, 1880, a medical student, aged nineteen, consulted me regarding the discharge of glairy matter from the urethra simulating semen, and staining his linen. Three years before he had gonorrhœa, and from that time until within the last year prior to my having seen him he indulged in great sexual excess. Patient used various remedies for his condition, amongst others tincture

FIG. 4.

of steel, with tincture of cantharides, and strong injections of nitrate of silver. The sexual organs presented no abnormality. On passing an instrument the entire urethra was found in a state of intense tenderness, being aggravated in the prostatic region. Thick glairy matter escaped from the urethra at stool, in which, however, the microscope revealed no spermatozoa. Nocturnal emissions happened often, and frequently unconsciously, being discovered in the morning simply by the effect on the linen; and pain was referred to the region of the prostate. Irritation having been subdued by the use of sedatives and bougies, a course of steel completed the recovery.

In the light of my experience of these cases, by no means infrequent, I am disposed to regard prostatic hyperæsthesia as consisting of two forms, the discharge in the one being characterised by the presence of spermatozoa, while in the other this element is wanting. It is preferable so to regard it, seeing that in other cases diurnal seminal losses, quite independent of straining at stool and micturition, are no doubt attributable to excesses, while others are to be ascribed to an idiopathic excitability of the sexual system. Of the latter, an example came under my observation in May, 1879.

H. E.—, aged twenty-six years and a half, never masturbated. The patient describes himself as in capital health, independently of his sexual system. When a lad of from thirteen to fourteen he says, in common with so many boys, he gave way to reading obscene books, and at fifteen had sexual intercourse, from which date seminal emissions began. At the age of eighteen he had emissions on an average once a week. At twenty-six years and a half (present age), emissions take place more than once a week. They occur at night both with and without erections. "If I lie on my left side, I may feel tolerably certain of having an emission, and then without erection." I find from my notes that strychnine and iron, with bromide of camphor, nux vomica, and watery extract of ergot, were prescribed; but there is no note as to the result. The etiology, pathology, and treatment of prostatic hyperæsthesia, as I regard them, are embodied in the foregoing observations. A few words of special amplification may not be out of place. Speaking generally, prostatic hyperæsthesia may be excited by any condition determining vascular plethora of the pelvic viscera. I do not think that it is invariably preceded by acute inflammation of the prostatic urethra as maintained by Dr. S. W. Gross, for I am persuaded that it may be due to passive congestion of the prostate and adjacent organs. I do not think that sufficient prominence is given to a contracted meatus, congenital or traumatic, as a cause of pro-

static and orchitic congestion. I have divided the meatus, in such cases, with the best results.

Therapeutics is the most vulnerable department of medical science. It may truly be regarded as the sanctuary of superficial reputations. As few thinking men attach much importance to by far the greater portion of what is recorded as to the alleged efficacy and influence of drugs—most of it begotten of incompetent observation—I record with diffidence my opinions as to the influence of remedial agents in the conditions under consideration. In chronic urethral and prostatic hyperæsthesia few means operate more beneficially than the passing of a full-sized metallic instrument into the bladder; the frequency with which this is to be performed should be inversely to the amount of irritation. As the ultimate facts of therapeutics are so few, I am of those who think that such as have been handed down to us ought to be cherished, and that the chimerical pursuit of new ones in connexion with new remedies is not unadvisedly to be encouraged. That bromide of potassium exercises a sedative influence over the motor sexual and urinary centre in the spinal cord is admitted to be one of the ultimate facts of therapeutics; nay in some cases so marked is this influence that when the drug is taken in large doses a temporary retention of urine is thereby occasioned. It is a modification of this toxic influence that we desiderate in bromide of potassium as a therapeutic agent. It is extremely probable that this impression extends along the whole anterior portion of the spinal cord. Reflex action is thus inhibited, and muscular excitability diminished. It seems to me that the sympathetic and the motor systems may be regarded as two opposite poles on whose properly balanced tone normal function, especially circulation, depends. Hence impressions on the sympathetic (fibres of Remak) which diminish its inhibitory power, exalt motor influence, and thus accelerate the circulation and determine congestions. If on the other hand motor influence is diminished, sympathetic dominance is correspondingly established. Bromide of potassium undoubtedly possesses the latter property. Thus it induces sleep by causing cerebral anæmia; and, by a similar influence on the pelvic viscera, operates beneficially in all cases of uro-genital hyperæsthesia and congestions. The bromides of camphor and iron seem to possess similar properties. Belladonna, and its active principle atropia, act apparently as therapeutic agents by stimulating the fibres of Remak, and are thus of acknowledged efficacy in the treatment of enuresis and spermatorrhœa; and atropia, according to Rosenthal,<sup>3</sup> and Dr. S. W. Gross, in prostatic discharges. When there is reason to suppose that there is an atonic condition of the prostatic ducts, such motor stimulants as strychnine and ergot of rye are specially indicated.

### ON ABSORBENT DRESSINGS.

CHIEFLY IN REFERENCE TO THE TREATMENT OF WOUNDS AFTER OPERATION.

By WM. BERRY, M.R.C.S. & L.R.C.P. & S.ED.,  
HON. SURGEON TO THE ROYAL ALBERT EDWARD INFIRMARY, WIGAN.

FOR some time I have used dry and infrequent dressings for my surgical cases in our infirmary here, and am so well satisfied with the results that I wish to relate a few cases thus treated. In treating the cases mentioned I have not been particular as to the material employed; sometimes fine oakum, other times absorbent wool, and salicylic silk also, have been used, neither did I mind having the wool made antiseptic, though no doubt this is an advantage where the discharges are fetid or unpleasant. In treating operation wounds I have striven to observe the three cardinal points—namely, (1) rest, (2) drainage, (3) pressure, based on physiological laws, and so much insisted on by Mr. Sampson Gamgee of Birmingham in his admirable little work on the Treatment of Wounds, and to whose kindness I am deeply indebted both for a supply of materials and many valuable suggestions. The convenience of this dressing can only be appreciated by the surgeon who constantly uses it, and, so far as my experience goes, the results will bear favourable comparison with other modes of treatment. In wound treatment we should particularly observe the three heads above-mentioned, for by employing a dry and absorbent material

next the wound, with firm and equal pressure and drainage, so as to allow the escape of all fluids from the wound, we render the necessity for dressing infrequent, and have everything favourable for healing. The importance, also, of observing the temperature chart closely each day, will enable us to discover the progress of the case; and so long as we have a temperature under 100° F., and the dressings externally dry and comfortable, we may leave the parts untouched without fear or risk to our patient.

The following cases have been satisfactorily treated by this method.

CASE 1. *Compound Comminuted Fracture of Thigh in a boy aged five years; Amputation of the Upper Third; Recovery.*—J. Mc—, aged five years, was admitted on February 4th, 1882, with a compound comminuted fracture of the right thigh, which he had sustained half an hour previously by getting entangled in the wheels of a cab. The femur was fractured in two or three places, the muscles torn and broken, and the knee-joint opened. Amputation at the junction of upper with middle third of thigh was performed by transfixion. All the bruised muscles were removed and the flaps brought together, the edges being secured by wire sutures. The stump was padded with absorbent cotton, a splint and bandage applied. He rallied very well from the shock and his temperature did not exceed 100° till the fourth day after operation, when it was 101.8°; after changing the dressing it went down in the evening to 98.8°. The dressings required changing about every fourth day; the temperature, however, again rose to 101.8° on the seventeenth day, but this could only be accounted for by one or two small abscesses on the other leg from bruises. The stump was almost healed by February 28th. A little red lotion and boracic lint was applied to hasten cicatrization. He was discharged to his home but readmitted a week after owing to a small superficial ulcer in the face of stump, and a few days after he was changed to another ward and took erysipelas of stump and other leg, but this subsided after appropriate treatment, and he was discharged on May 25th.

CASE 2. *Scirrhus of Breast and Axillary Glands; Excision; Wound of Vein; Recovery.*—(For notes of this case I am indebted to Mr. A. W. Stone, junior house-surgeon.) J. F—, aged thirty-four years, single, factory hand. Admitted March 25th, 1882, with the following history:—Has had good health all her life until three or four years ago, when she felt a lump the size of an egg on the outer side of right breast; this was not painful, but tender to the touch, it gradually increased in size till now, when it is about the size of a closed fist. No retraction of nipple, but a nodule of hard tissue two inches above breast, and the axillary glands appeared enlarged. Could find no family history of cancer. On March 30th the breast was removed by an incision, which was carried into the axilla, and the glands here were found much larger and more matted together than at first sight appeared. The vessels were completely surrounded by hard masses; these were removed, and in doing so the axillary vein at its junction, with the cephalic, was wounded; two ligatures were applied. After the glands were removed and the bleeding stopped, a drainage-tube was inserted, the edges of wound carefully brought together by wire sutures; pads of salicylic silk and a bandage were applied. The temperature was 100° the morning after operation, and there was some pain all along the arm, which was enveloped in flannel. The temperature was never more than 100° F., and after dressing on the third day the temperature was normal and remained so. After the first few days carbolised tow was used owing to the abundance of discharge, but the wound granulated well, and she was discharged cured on May 14th, 1882.

CASE 3. *Myeloid Tumour of Femur; Amputation through Hip-joint; Recovery.* (I am indebted to Mr. Stone for notes of this case.)—H. D—, aged nineteen, single, clogger, was admitted on April 19th, 1882, under the care of my colleague, Mr. Monks, and for whom I took charge of the case. His family history revealed no hereditary disease, and he himself enjoyed good health until he was thirteen years of age, when he was in the infirmary for five weeks, suffering from "rheumatics in both knees." He was discharged cured, but says he has had the same complaint about once a year ever since. On March 17th he slipped and fell, and hurt his knee. This had been treated with rest and cold applications. On his admission he complained of great pain and inability to move the joint; there was a globular swelling in front, extending a little upwards on the femur, and also on each side of the joint. The tumour was elastic and semi-

<sup>3</sup> Wiener Klinik, May, 1880.

fluctuant, and appeared to extend into the joint. Circumference at upper edge of patella sixteen inches and a half, and considerable pain on pressure. The patient was ordered to bed, and a back-splint applied to fix the knee, lead lotion constantly applied, and five grains of iodide of potassium three times a day given internally.—May 10th: Measurement over knee at edge of patella, seventeen inches and a half; pain much increased; compound soap pill every four hours. I now took charge of the case for Mr. Monks.—May 18th: Pain very great. Leg one inch and a half shorter than the other, measures seventeen inches and a half over patella. Patient decidedly cachectic looking. A consultation of the staff being held, an exploratory incision went through the bone into a soft, reddish, and pulpy mass. The majority of the staff thought amputation through the hip-joint should be performed, and Mr. Woodcock, one of my colleagues, undertaking to control the hæmorrhage, an Esmarch elastic tourniquet with a roller was applied round the abdomen. I proceeded to make the anterior flap by transfixion, Mr. Woodcock following the knife with his fingers. The femoral was secured, and the posterior flap made. The limb was disarticulated without much trouble, and the arteries secured with catgut, the bleeding having stopped (little blood being lost), a drainage-tube was placed between the flaps, and the edges brought together by wire sutures. Absorbent cotton was evenly placed around the flaps, and a bandage applied. The man was in a state of collapse, but with the administration of warm drinks gradually rallied. His temperature chart from the time of his admission till now shows a temperature varying from 100° to 103° F. The morning after the operation there was a feeling of sickness and exhaustion, although he had had a tolerably good night. Temperature 103°; this declined, but on the 22nd, four days after the operation, it rose to 103·8°. The dressings were removed, the edges of the wound found looking well. After cleansing the parts, absorbent wool was applied. The temperature had fallen next morning to 98·2°.—May 24th: Morning temperature 98·2°; evening 102. He feels better, and takes liquids better; no solid food allowed as yet. Dressings changed. The case now progressed favourably without interruption, the sutures being removed when found to be useless, and support from strips of plaster took their place. He was discharged on June 20th, with the wound quite healed and much improved in general health.

**CASE 4. Compound Comminuted Fracture of both Bones of the Leg; Secondary Amputation below the Knee; Re-amputation (Carden's); Recovery.**—M. C—, aged twenty-six years, single, a brakesman, was admitted on March 29th, 1882, with a compound comminuted fracture of both bones of the leg. This was put up antiseptically. Cellulitis, however, supervened, and eight days after he had an evening temperature of 103°. On April 5th amputation was performed just below the knee-joint, and dressed antiseptically. The temperature fell to 99° in the morning, and 101° in the evening. On April 13th, eight days after amputation, the evening temperature rose to 103°. Quinine and antipyretics were now given freely, but on May 8th his evening temperature rose to 105°. This declined to 102° after relieving the stump of some pent-up pus. On May 15th the evening temperature registered 104·8°, and on the 17th 104·6°, and pus was found in the knee-joint. On May 18th I took charge of the case, and amputated through the condyles of the femur (Carden's operation). An abscess-cavity was found running between the muscles, half way up the thigh; this was sponged out with carbolic lotion. The flaps were united with wire sutures, and a drainage-tube inserted. Absorbent cotton was applied, and a back splint evenly bound on with a bandage. The temperature the same evening was 102·6°, and the next morning 99°.—21st: Evening temperature 103·8°; patient feels much better; losing his hectic appearance; dressings changed; stump looking well; healed in several places.—May 25th: Seven days after amputation the temperature was 98·4° in the morning, and 99·6° in the evening. Four more dressings served to complete the healing, the sutures being removed as occasion required. Three weeks after the operation the stump was quite healed, the man much improved in health and strength, and he was discharged cured on July 4th, 1882.

Through the kindness of Mr. Gamgee I have just received from Southall Brothers, Birmingham, some iodiform pads for surgical cases. They are exceedingly nice and light. It is much better to have the absorbent wool enveloped in this absorbent material, so as to prevent its adhering to a wound.

## THE MICROSCOPE IN DIARRHOEA.

By KENNETH W. MILLICAN, B.A. CANTAB.

THE use of the microscope as a common aid to diagnosis and treatment must inevitably take a prominent place in the future; and the demonstration of the bacillus tuberculosis by Koch, and the subsequent and progressive simplification of the process by Ehrlich, Baumgarten, and Heneage Gibbes, show how indispensable this instrument will become in the not far distant future to the practitioner of medicine. A series of cases of diarrhoea have recently occurred in this district in which certain features of interest were observed. The patients were all attacked when a few days of very hot weather had been followed by considerable rain. A sort of period of incubation occurred, during which the patients were depressed and out of sorts, and this was followed by a prostrating attack of diarrhoea. The stools were fluid, not unlike those of typhoid fever, and contained in every instance, small gelatinous or albuminous lumps like half-cooked white of egg. The odour was extremely offensive. Beyond the prostration, however, and general gastric disturbance, with excessive flatulent distension and pain, there were no constitutional symptoms. In no case was there any marked rise of temperature, nor was the pulse greatly affected.

Having several cases at the same time under unsuccessful treatment by astringents, powdered aromatic chalk with opium, &c., I submitted the evacuations to microscopical examination. This showed them to be swarming with bacteria, and the indication for treatment drawn from the examination was carried out by the exhibition of one grain and a half of carbolic acid in compound tincture of cardamoms and peppermint water every four hours. The later cases were treated by the exhibition of five minims of terebene in mucilage every three hours. This treatment proved in the highest degree satisfactory, for the unpleasant symptoms were speedily and effectually checked.

The method of examination for bacteria which I have found successful is very simple. The stain used is a solution in distilled water of "navy blue," one of Tomlinson's aniline dyes. I have generally used it of a deep-blue colour, but not of any particular strength. A lump of the gelatinous matter before referred to is well smeared over the surface of the cover glass and allowed to dry. The cover glass is then floated on the dye for five or ten minutes, at the end of which time it will be found well stained. It is then washed in dilute nitric acid (1 to 3) and finally in distilled water. The cover slip is then allowed to dry, which may be aided by gentle warmth from a spirit lamp, and mounted in Canada balsam. Evaporation is a better method of extracting the water previous to mounting than immersion in alcohol, for I have found the alcohol to obscure the lustre of the aniline dyes. If preferred after the washing, the cover slip may be floated on a solution of aniline brown, made from another of Tomlinson's dyes in a similar manner. These dyes are excellent in microscopic staining, and are moreover cheap, and easily made as required. The most useful appear to be magenta, navy blue, and Bismarck brown. The violet has not proved so successful in my hands. The bacteria so observed consisted of small refractive granules (micrococci!); short, fine rods (bacilli); long, fine-pointed rods; and curled, twisted ones. There were also mycelium-rods, frequently stretching right across the slide. All these were well seen with  $\frac{1}{2}$  in. object-glass, and even with  $\frac{1}{4}$  in. It is of course to be noted that the evacuations should be obtained as fresh as possible for examination. I directed terebene to be at once placed in those that were put aside for me, and they were then well covered up.

Aitken speaks<sup>1</sup> of "the presence of a bacteria development in the stomach and intestines, under the name of *mycosis intestinalis*." The class of cases, however, to which he refers, appear to be of a much more serious character than my own, and are said to occur "suddenly during apparently robust health, quickly followed by lividity of hands and face, collapse and death in from two to six days."

## A CASE OF RECOVERY AFTER A BROKEN NECK.

By C. JORDISON, M.R.C.S.

ON Oct. 26th, 1881, Mr. C. S. P.—, aged thirty-eight, when out cub-hunting, was riding at a canter over a fence under the arm of an oak tree, when his horse jumped much higher than he expected, and the back of his neck came in violent contact with the concave surface of the branch. Mr. P— was leaning very forward over his horse's neck, and as the horse jumped almost perpendicularly upwards, the force of the blow was forwards and downwards. He was knocked off his horse, and lost consciousness for about two minutes. As soon as he could speak, he complained of intense pain up and down the neck and in his arms and legs. In less than ten minutes I was with him, when his first words were, "I am done for; my arms are paralysed, and the paralysis is extending over my body and into my legs." I noticed the respiration was normal. We carried him on a gate to the nearest farmhouse, where, after examination, I came to the conclusion that there were fractures of the laminae of the fifth and sixth cervical vertebrae. At this time there was complete paralysis both of motion and sensation of the left upper extremity, and almost so, though to a less extent, of the right; impaired mobility of the left leg, the right being unaffected, and a sense of tingling and numbness over the whole body; there was perfect consciousness, and great pain in the neck and shoulders. He was laid upon a hard and perfectly flat mattress, with the head on a level with the shoulders, and this was kept immovable by sandbags. On the following day Mr. Bicketsteth, of Liverpool, saw the patient with me. He concurred with my diagnosis, and we agreed that the paralysis was from injury to the roots of the fifth and sixth spinal nerves, and that the numbness of the body and partial paralysis of the left leg were due to extravasated blood outside the sheath of the cord. There was of course paralysis of the bladder, and for a few days slight difficulty in swallowing. The temperature never rose above 101.4°. There was for a few days slight delirium and occasionally very great flushes, the whole head, neck, and face becoming of a deep-red colour, and this was always succeeded by great restlessness and irritability. By the third day he had entirely recovered motion in the left leg, and there was only slight tingling as far as the knee.

The treatment was absolute rest, but on the ninth day it was essentially necessary to change the bed linen, &c.; and whilst this was being done crepitus was distinctly felt by the trained nurse, and heard by my assistant and myself. After this time the head was not moved again for many weeks. By the fourteenth day he had much greater power in the right arm, and he could just raise the left, but could hold nothing between the fingers; there were still numbness and tingling over nearly the whole body, also paralysis of bladder and sphincter ani. Perfect power of motion in both legs. Temperature 98.2°, pulse 99, respiration natural. There was a large amount of extravasated blood under the skin as far as could be seen down the neck, and extending from the spine to the left shoulder-point. After this time the paralysis of the arms became gradually worse, until at the end of the fourth week there was then complete loss of power of motion over the left arm and hand, accompanied with intense hyperæsthesia; almost complete paralysis of the right arm and hand, but less hyperæsthesia. On the left side there was complete atrophy of the hand, arm, and shoulder, the two pectorals being the first to waste away; on the right side there was also some atrophy, but to a less extent.

This condition of utter helplessness continued without material change for about a week, when the power of emptying the bladder and of making an effort at defecation began very gradually to return, and slowly the power of moving the right arm was recovered so that by the eighth week he could hold an envelope or toothpick, but could not support a light book or even a newspaper. By the end of the eleventh week he could do as much with the left arm, the hyperæsthesia was gradually subsiding, but all the joints of the left arm and hand were very stiff and gave us much trouble. At this time he could slightly raise the head from the mattress and could rotate it freely. At the end of the

thirteenth week I had my patient carried a distance of four miles on a stretcher to his own house, after which he began to make rapid strides towards recovery, and as the callus from around the fractured ends of the bones was absorbed, and the muscles again received their nerve supply, so he gradually recovered normal sensation in both arms and over the trunk and less rapidly the power of motion. At the end of the sixteenth week he was up and walking about; there was decided prominence over the seat of the injury, and the head was unnaturally tilted forward, but only to a slight extent, so slight that it would not be noticed by anyone who had not known Mr. P— before the accident. The sensation and motion in the right arm were perfect, the sensation in the left nearly so, but there still existed great weakness, although there was no perceptible or measurable difference in the size of the two arms, the muscles having become developed more rapidly than they atrophied. At the end of the twenty-fifth week my patient was riding, driving, rowing, and swimming, having gone to Margate (by the advice of Mr. T. Bryant, who saw him about this time), and with the exception of a slight weakness in the left arm was perfectly well and strong.

*Remarks.*—I think undoubtedly we had here an injury to the spinal nerves by the broken fragments of the injured vertebrae, as the paralysis, numbness, &c., were instantaneous. The paralysis of the left leg came on after a few minutes, and was probably due to blood extravasated outside the sheath of the cord. I think the extreme paralysis about the fourth and fifth weeks was due to callus thrown out around the end of the broken fragments pressing upon the nerves as they emerge through their canals, and as this callus became absorbed so the power of motion, the sensation and the growth of the muscles were gradually recovered, and the now continuing weakness I attribute to there having been some slight laceration of the sheath of the nerve as it emerges from its canal, and the resulting thickening pressing upon and destroying some of the nerve fibres. I attribute the unusual and happy result primarily to there having been no interference with the respiratory tract, the injury having occurred just below the point of origin of the phrenic nerve, which possibly, in this case, did not receive a communicating branch from the fifth cervical; and, secondarily, to the great muscular development of my patient enabling him to withstand the ill effects of long-continued pressure without the usual consequences, and to the fact that although the spine was broken the spinal cord was not injured.

Malpas.

## NOTES ON A CASE OF PRURIGO FEROX; TREATMENT AND RECOVERY.

By SURGEON SHIRLEY DEAKIN, F.R.C.S. ENG.,  
OFFICIATING JUNIOR CIVIL SURGEON, ALLAHABAD.

AS cases of Hebra's prurigo, fortunately for the unhappy patients, are rare in England, the following notes of a case successfully treated may be of interest. Dr. Tilbury Fox states in the last edition of his valuable work on "Skin Diseases," p. 156, that he had only met with one case. The case under observation presented little in common with cases of Scabies ferox, or Malabar itch, which are fully described in Drs. Fox and Farquhar's "Skin and other Diseases of India and Hot Climates," pp. 65 and 267.

Constable N—, aged fifty-two, a Punjab Mussulman, was admitted to the Police Hospital on Oct. 26th, 1878, suffering from severe itching of the skin of the whole surface of the body, excepting the palms of the hands and the soles of the feet; the back of the hands and the front of the feet, however, being especially troublesome.

*Previous history.*—Has suffered much from periodic (so-called "malarial") fever in past years. States that twenty-two years ago, at Peshawar, the eating of *bharra*, a kind of sheep, used to give him fever constantly. He denies a syphilitic history.

*Present history.*—Six months since he first noticed a severe itching between the shoulders, and presented himself at the hospital a month later on. Then he had much heat in the skin, and perspired freely during the night. When I saw him first the skin was but slightly thickened. Both lenses exhibited an advanced cataractous appearance, a condition very common at his age among natives of India.

Bowels regular; tongue clean and firm; passes his urine slowly, but his febrile condition prohibited any attempt at exploring the urethra. He has a reducible right inguinal hernia, and there is a small swelling over the site of the left internal ring.

*Present state.*—The whole of the skin, excepting that over the scalp, chin, armpits, groins, and hernial sac, is much infiltrated and thickened. When uncovered the patient shivers greatly. He is terribly tormented with a constant itching, and scratches at his skin in a most distressing manner. His beard has fallen out, and the hair on his chest, which was abundant, has also disappeared, likewise the hair from the scalp; the moustache is firm. There were numerous slight abrasions all over the skin, caused by his nails; these rendered it difficult to decide whether the patient suffered from phthiriasis or not; repeated examination, however, did not reveal any parasite.

*Treatment* was first commenced with three hot air baths with sulphur, quinine and iron being given internally, and weak carbolie oil, one in forty, freely applied over the skin. Subsequently he took five minims of solution of arsenic three times a day, and applied sulphur ointment, and then linseed oil only. Potassium iodide in fifteen-grain doses twice a day, first alone, and afterwards with the addition of one-sixteenth of a grain of chloride of mercury, produced no effect; and on December 15th, after six weeks' treatment, he was sent to his home in the Punjab on two months' sick leave no better. He was readmitted to hospital on February 20th, 1879, on return from sick leave, no better for the change. His state is thus noted: skin much thickened, as before described, and though he is fairly nourished he is much troubled by the itching. Ordered fifteen grains of powdered ergot twice a day. To have an alkaline bath: three ounces of bicarbonate of potash, two ounces of bicarbonate of soda, one ounce of borax, and one pound of bran, in thirty gallons of water. To use as a lotion: one drachm of hydrocyanic acid, two drachms of borax, one fluid ounce of solution of acetate of ammonia, in eight ounces of water. During his stay in hospital he had four baths as above, and took ergot for more than one month. He applied the lotion, using a bottle in eight days. Subsequently he took five minims of solution of arsenic three times a day. Small lumps appeared on the skin somewhat resembling mosquito bites, only often they were much larger, measuring an inch across. They were hard, raised, and redder in colour than the surrounding skin. Each remained for half an hour or so, and then died away. When at his worst, some fifty or sixty such tubercles appeared daily.

Under treatment his condition greatly improved, the thickening of the skin disappeared to a large extent, the inner surfaces of the thighs remaining the worst. On the 24th of June he was convalescent and discharged to duty, doing his duty well until, on the 5th of October, 1879, he came up for examination previous to his discharge on pension. His state was then as follows:—Infiltration has disappeared from the skin of the face, and the face, consequently, looks much smaller; he has lost the peculiar smile, which recalled the risus sardonius to one's mind, and which was due to excessive thickening in the region of the zygomatic and risorius muscles, and about the eyebrows. His beard has grown again thick and long; it is four inches in length, and the hair is quite black, as is also the hair on his chest, which has grown again luxuriantly. Before his illness the hair was nearly white. The hair on his head and in his moustache is now abundant, and of a dark-grey colour. He has not taken any medicine since he left hospital. Shortly after his discharge from hospital he came to the native doctor, Hospital Assistant Ram Lal Das, and asked him whether he had been given arsenic in hospital. His reason for doing so was that his friends had attributed the change in the colour of his hair to the administration of arsenic. It appears that the effect of arsenic in causing hair to become black is well known to natives. I have consulted Neale's Digest, Ringer, Fox, and Bartholow, but cannot find any reference to this therapeutical effect of arsenic. There is still some slight itchininess of skin on the inner sides of the thighs, and slight thickening on the inner sides of the forearms. He is now free from the troublesome perspiration. The gums are slightly spongy; a scorbutic tendency, however, is generally prevalent among the poorer natives, owing to the scarcity of vegetables and high price of food stuffs now current in this district. The man is well satisfied with his changed condition. When first treated, Dover's powder, belladonna, and

ether were given to check the perspiration, but without effect. Ether, for suggesting the use of which in checking perspiration I am indebted to Dr. Balthazar Foster, has generally been in my hands most successful in doses of from ten to twenty minims of spirits of ether. It, however, is very volatile, and any mixture containing it should be dispensed daily and kept in a glass-stoppered bottle.

Allahabad.

## NOTES ON A CASE OF HÆMATO-CHYLURIA.

By JOHN D. HILLIS, F.R.C.S., F.R.M.S.

ON March 26th last a sample of urine was forwarded to me for examination, together with the following history.

W. E. B—, aged forty-two years, a coloured Creole of Demerara, stout and florid, has been for the past two years suffering from intermittent hæmato-chyluria, previously to which he had always been a healthy man. The patient is not losing flesh, but complains of an aching pain in his loins. Normal quantity of urine is secreted daily; skin acting well; pulse and temperature normal. On cooling, the urine is said to become like blancmange. The specimen of urine was of the colour of port-wine; reaction neutral; specific gravity 1025, and contained a quantity of albumen. Examined microscopically, the fluid was covered with well-defined red blood-corpuscles, the urine also contained vesical mucus and some crystals of triple phosphate. It was late in the evening and only a cursory examination could be made. On March 30th I examined another specimen which contained a quantity of fatty granules, crystals of triple phosphate, a few chyle- but no blood-corpuscles; and there were a few cells of bladder epithelium, but no filaria could be discovered after a very careful examination. On April 5th another specimen of W. E. B—'s urine was examined with  $\frac{1}{2}$  and  $\frac{1}{4}$  objectives. There were fewer red corpuscles, but an adult filaria sanguinis hominis was discovered on the second slide examined. I advised the patient being placed on decoction of rhizophora racemosa, which I have found most useful in cases of chylous urine. Under this treatment the patient considerably improved, the blood has entirely disappeared, and the urine does not coagulate on cooling. He states that "occasionally his back aches, and then his water becomes a little cloudy." I have had no further opportunity of examining either blood or urine, as he lives in a neighbouring county; but I can strongly recommend the mangrove bark in these cases.

## HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

## GREAT NORTHERN HOSPITAL.

### TWO CASES OF GUNSHOT WOUND; REMARKS.

(Under the care of Mr. SPENCER WATSON.)

FOR the following notes we are indebted to Mr. Wharry, house-surgeon.

A man having shot his wife, attempted his own life. On June 6th Robert C—, aged fifty-one, was admitted in the afternoon with four wounds on the right side of his scalp, all down to the bone. These had been caused by his discharging a revolver at himself. There was a good deal of hæmorrhage on admission, which was controlled by pressure. The wounds were enlarged, and search was made, but no bullets were discovered. Water-dressing was applied. The patient passed a restless night, and appeared next morning in a very depressed condition, continually lamenting over his condition, past and present. Pulse quiet; tem-

perature not raised; he took his breakfast; wounds looking well. On the 9th he appeared more restless; the scalp was rather puffy around the wounds, and discharging a little; poultices were applied; temperature 101°; pulse quiet. Next day he was in much the same condition, the temperature falling to 99·8°; wound discharging; complained of a good deal of pain in the head. On the 12th the temperature was 99°; wounds discharging freely; very restless. On the 13th in the evening the temperature was 104°; scalp more puffy; a bullet, very much flattened, was extracted from the wound over the forehead. On the 14th and next day there was slight improvement, the general condition being good; temperature 100°. On the 17th the temperature was in the night 104°. On the 19th the wounds were discharging freely; other conditions good; temperature 102°. On the 20th the temperature in the night was 103°; much pain in head; wounds discharging; slept well. On the 22nd the wound over the parietal bone was enlarged, and another bullet was discovered considerably flattened, and removed. On the 25th the patient was much better, and the wounds showed a disposition to heal.

The patient was discharged on July 15th, with the wounds quite healed. The man had apparently recovered from the effects of his injuries. During the whole of his stay in hospital he was given chloral and bromide of potassium every night.

Mrs. C— was admitted on the same day with a small circular wound, about an inch and a half behind the right ear, just over the apex of the mastoid bone, which was stained with gunpowder. The wound apparently extended in a downward direction into the soft parts of the neck. A search was made for, but no bullet discovered. The wound healed up under water-dressing in ten days, without any discomfort to the patient, beyond some slight stiffness of neck.

*Remarks by Mr. SPENCER WATSON.*—The slight amount of damage that can be inflicted by a saloon pistol, even discharged at close quarters and into a vital part, is well illustrated by these cases. The man who is said to have made the attempt on his wife's and his own life had been injured in a railway accident about six months before, and had ever since been much changed, his right arm and leg having been partially paralysed. In spite of the solatium of substantial damages awarded him by the court before whom the case was tried, he did not recover either mentally or physically, and when he attempted the acts alluded to he was no doubt under the influence of delusions. The wounds inflicted were very insignificant. All seven chambers of the revolver had been discharged, and two of the pellets were found on the spot. These were conical, and of the size of large peas. To test the penetrating power of the revolver, the police loaded and discharged it at a distance of five feet from a half-inch deal board. The bullet easily passed through. This weapon must have been discharged by C— at his wife when her back was towards him at about the distance of five feet, and the shot passed into her neck immediately behind the mastoid process. She had literally no symptoms referable to this injury, and three months after it was as well as ever, the pellet still remaining embedded somewhere in the muscles of the neck. In the case of C— there were very slight symptoms of surgical fever, which, however, soon passed off when the pellets were extracted.

#### NORTH STAFFORDSHIRE INFIRMARY.

CASE OF PREGNANCY WITH RETROVERSION OF UTERUS,  
CAUSING RETENTION OF URINE (160 OZ.);  
FATAL RESULT; REMARKS.

(Under the care of Mr. SPANTON.)

MARY ANN H—, aged thirty, married, was admitted into the infirmary on July 2nd, 1881, for supposed abdominal tumour. She stated that she had usually good health, and believed herself to be about four months pregnant, as menstruation had ceased for that length of time, and the areolæ of the breasts indicated it. For a fortnight before admission no urine had been passed. She complained of great pain in the hypogastrium, and the abdomen was much enlarged, with dull percussion from the pubis to above the umbilicus, and extending to the iliac regions. The lips were dry, the tongue brown, and strength much exhausted. Frequent sickness both before and after admission. The legs and

vulvæ were cedematous; bowels constipated. She had been under the care of a medical man previously. A catheter was at once passed and 160 ounces of urine drawn off, giving great relief. The following day 70 ounces were obtained, quite dark from admixture of blood and blood-clots. Considerable faintness followed this, and stimulants and astringents were freely administered.

On examination the body of the uterus was felt to occupy the whole of the posterior portion of the pelvis, pressing upon the rectum and neck of the bladder. The os uteri could not be felt; the uterus was enlarged to the size of about the fourth month of pregnancy. Mr. Spanton desired to attempt the reduction of the retroversion, but to this the patient would not then consent. A consultation of the staff was held, and the next day, chloroform being administered and about seventy ounces of bloody urine withdrawn from the bladder, Mr. Spanton passed his hand up to the uterus, the fundus of which felt like an enormous child's head, so that there was barely room for the hand to pass. The os uteri was high up behind the symphysis pubis, and the uterus appeared to be literally "upside-down." By continued steady pressure with the palm of the hand the uterus was felt gradually to rise into its normal position above the brim of the pelvis, and the cervix was then felt in the centre of the vagina. Once replaced, there seemed no tendency for the uterus to fall back, and on recovery from the anæsthetic the patient felt greatly relieved. In the evening fourteen ounces of urine mixed with blood were drawn by catheter, after some had been passed naturally. Signs of exhaustion with sickness continued, and the patient gradually sank and died at 11 A.M. on July 6th. No post-mortem examination was allowed.

*Remarks.*—The case is of interest as illustrating one of the grave dangers of neglected retroversion during pregnancy, and as showing to what an enormous extent the bladder may be dilated without actual rupture. The case was sent in as one of ovarian disease, and casually had the appearance of one; but the catheter quickly solved that doubt; and it was indeed unfortunate for the patient that such a simple measure was not employed earlier, as it is quite possible that the extreme distension of the bladder helped to exaggerate the retroverted condition of the uterus, which was, in its turn, originally the cause of the retention.

#### KASHMIR HOSPITAL.

CASE OF COMPLETE CONGENITAL OCCLUSION OF THE OS  
UTERI; OPERATION; RECOVERY.

(Under the care of Mr. E. DOWNES.)

In the month of August, 1877, a young woman, aged about twenty-two, married, applied at the hospital. Her abdomen was very prominent, as if from pregnancy. It appeared, however, that she had never menstruated. Her abdomen was tense, and the tumour ascended nearly to the ensiform cartilage; it was oval and smooth, but not very movable. A vaginal examination was suggested and finally agreed to. The tumour was felt distinctly, and with one finger in the vagina and the other hand externally the tumour, which was quite hard, could be moved. There was no tenderness. What was believed to be the os uteri was also felt so open that the finger could easily have been pushed into it, but it was not thought wise to make any further examination until arrangements for operation were completed. There was no cervix uteri to be felt, and very little vagina, but the cervix had apparently been obliterated by the tumour. The canal which was taken to be the os uteri was close to the symphysis pubis.

A diagnosis was made of a fibrous tumour of the os uteri. The patient was told that she was suffering from a very serious disease which required an operation, but that the risk was great. Her suffering was so great that both she and her husband begged that something should be done.

She was admitted into hospital. Her treatment for about a week consisted merely in giving her perfect rest and small doses of opium to relieve the distress, paying attention to the bowels at the same time. Every day she begged for the operation. Another medical man saw the woman with Mr. Downes and examined her carefully externally and by the vagina, but did not use the sound.

After about ten days Dr. Ross, the civil surgeon, arrived in Srinagar; he and Dr. Williams of the Indian Medical

Service were both present. The patient was put under chloroform, and then a thorough examination of the parts was made. She was placed in the lithotomy position and the parts exposed to view. It was found that what had before been taken for the os uteri was the meatus urinarius, which was enormously dilated, apparently by having been used instead of the vagina in sexual intercourse; this became still more certain by passing a finger into the bladder. On looking carefully into the small space which represented the vagina a little white spot could be seen in the mucous membrane, surrounded by a less distinct whitish ring; this white spot apparently marked the position of the os uteri, but it was so completely closed that it could not be felt by the finger.

It was now evident that this was a case of complete congenital occlusion of the os uteri, and the enormous tumour, reaching nearly to the ensiform cartilage, was an accumulation of menstrual fluid. The point of a small conical canter iron, heated nearly to redness, was pressed firmly in the position of the os uteri; the iron at once cut through the mucous membrane and the small amount of tissues beyond, which extended at the most only about a quarter of an inch, and sank into the uterine cavity, from which issued a thick fluid of a blackish-red colour, perfectly opaque, and almost devoid of smell. Dr. Ross pressed on the fundus of the uterus, and after much of the contents had been discharged, a very distinct hour-glass contractions of the womb was noticed; gradually this gave way, and by gentle pressure on the fundus the whole contents of the uterus, about six pints, were discharged. The last part consisted chiefly of clots and shreds, and were expelled by dilating the os with the finger. The uterus was well washed out with tepid water containing about 2 per cent. of carbolic acid. There was no hæmorrhage from the incision, and it was dressed with lint and carbolic oil. A firm bandage was applied round the abdomen, and a good pad placed over the uterus, which had contracted well.

The woman was placed in a room by herself, removed altogether from the other patients, and her husband undertook to nurse her. One of the dressers was ordered to change the dressings twice a day, and to introduce a large bougie into the new os uteri every morning; and ergot was ordered to be given internally. When she recovered from chloroform she had no pain, and expressed herself immensely relieved by the operation. For some days there was a considerable bloody discharge from the womb.

After the operation all went on well for three days; the temperature during that time was normal. On the fourth day she complained of a bad cough, and such great difficulty in breathing that she had to be propped up in bed. Her temperature was 105° F. Twenty grains of salicylic acid were given every hour. A dose was given at once, and the temperature fell a degree; after the second dose it fell to 101°, and after the third dose to 100°. After the second dose she expressed herself to be very much relieved, and said that she felt so hungry that she asked for food; after the third dose she felt rather nauseated, and the salicylic acid was ordered to be given only every four hours. Next day the temperature was normal, and the salicylic acid was stopped; the cough and dyspnoea remained troublesome. Nothing amiss could be detected with the stethoscope. A simple cough mixture was given. After exactly a week the temperature again rose to 105° in precisely the same way, and was as speedily reduced to normal by salicylic acid. It did not again rise while she remained in hospital, and the cough and dyspnoea gradually disappeared.

The rest of the story is soon told. A month after the operation she insisted on going home. She has not been heard of since. When she left the hospital she was much improved in every way; the discharge from the uterus had ceased; the os uteri was nearly natural in size and shape; the vagina was longer than before, though still much shorter than it should have been; a cervix uteri could be distinctly felt in the vagina. Her general health was very much improved; she was fairly strong and in excellent spirits.

**ST. MARY'S HOSPITAL, MANCHESTER.**—At the quarterly meeting of the trustees and subscribers to this hospital, the chairman had to express regret that the appeal put forth in March for means to wipe out the debt encumbering the institution had been but feebly responded to. He had the gratification of announcing, however, that Mr. James Jardine had generously given them a cheque for £500 in aid of the funds.

## Medical Societies.

### PATHOLOGICAL SOCIETY OF LONDON.

*Ulcer of Duodenum.*—*Diaphragm deformed through Rickets.*—*Aneurism in Children.*—*Aneurism of Aorta and Abnormality of Heart.*—*Obturator Hernia.*—*Tricuspid Stenosis.*—*Parovarian and Broad Ligament Cysts.*—*Gangrene of Fingers.*—*Mediastinal Tumour.*—*Perforating Ulcer of Colon.*—*Cirrhosis of Liver.*

THE first meeting of the present session of the Pathological Society was held on Tuesday last, Oct. 17th, S. Wilks, M.D., President, in the chair. There was a very full attendance of members. It was noteworthy that there were no "card-specimens" exhibited. The President prefaced the business of the evening by an appreciative reference to the late Dr. Peacock, one of the earliest members and a former President of the Society. Dr. Wilks said that during the recess the Society had lost one member to whom he felt compelled to make a passing reference. Dr. Peacock formed one of the small band that met many years ago to found the Society. He was one of its earliest and most valuable contributors, and at the last meeting but one he showed a specimen of malformation of the heart, a subject on which he had won a world-wide reputation. His career was a most enviable one; he was not ambitious as regards practice with its emoluments, and was thus able to devote himself with undivided attention to his hospital work, and in the autumn could travel and devote himself to science and literature. He had been a model member of the Society, and he could not allow that occasion to pass without a brief reference to one who for many years had been so closely connected with it.

Dr. NORMAN MOORE showed several specimens. 1. A circular ulcer, as large as a fourpenny piece, situate in the duodenum, just outside the pylorus. Its base was adherent to the pancreas, and at one point the ulcer had penetrated a considerable branch of the pancreaticoduodenal artery. This perforation was the cause of death. Post mortem the whole intestine was distended with blood, but there was none in the stomach. The patient was a man aged thirty-four years. His first symptom was a hæmatemesis of about a pint at 10 P.M. on May 9th. He came to St. Bartholomew's Hospital at 11 P.M., looking much blanched. After admission he vomited blood again at 2.30 A.M., and a second time, more copiously, at 6.30 A.M.; he became collapsed and died at 8 A.M., ten hours after his first sensation of illness. 2. A deep ulcer, in parts healed, also situated in the duodenum close to the pylorus. Its floor was partly formed by the adherent pancreas, and partly by peritoneum. The patient, a bricklayer, aged forty-nine years, had complained of a slight degree of pain after eating, for three months, but not to a sufficient degree to make him apply for treatment. He died of a severe pulmonary catarrh. 3. Enlarged Ribs of Rickets pressing upon the Liver through the Diaphragm. A cast of the under side of the diaphragm showed three large beads on the seventh, eighth, and ninth ribs. These pressed upon the diaphragm and through it upon the liver, causing well-marked depressions on each lobe. From a rickety child aged one year and eight months. 4. A drawing showing Depressions in the Liver due to Enlarged Ribs in another rickety child aged one year and seven months. These depressions perhaps appeared larger post mortem than they would during life, but certainly indicated a permanent pressure of the enlarged ribs upon the liver, a pressure increased by the fact that both children had constricted chests. He suggested that the slight thickenings sometimes observed in the capsule of the upper part of the liver in children and in adults might be due to the pressure of beaded ribs through the diaphragm. 5. An Aneurism of the External Iliac Artery, from a girl aged seven years. The aneurism was at the origin of the external iliac on the right side, and it was a dilatation of the vessel extending more to the inner than to the outer side. Its cavity was filled with firm laminated fibrin. A microscopic section showed that the aneurism was

a simple dilatation of the vessel, all parts of which were represented in the wall. There was a marked increase of nuclei in the middle and deepest layer of the inner coat. No other aneurism was found. On the mitral valve there were some small growths, and on one aortic cusp there was a very large calcified growth. The aorta itself was free from any obvious morbid change, and a microscopic section showed it to be perfectly healthy. The girl had died suddenly. The aneurism would appear to have been due to an embolus from the aortic valves, followed by a deposit of fibrin, in the method of formation first suggested by Dr. John Ogle in the Path. Soc. Trans., vol. viii., p. 163 (1837), and afterwards more fully treated of by him in a paper in the *Medical Times and Gazette* for Feb. 24th 1866, and by Mr. Callender in the Path. Soc. Trans., vol. ix., p. 93. 6. The Heart and Aorta of a girl aged five years, showing an aneurismal bulging a quarter of an inch above the Aortic Valves. The aneurism was due to an ulcer on the posterior wall of the aorta, which was associated with an ulcerative endocarditis of the aortic valves. There were also minute growths on the mitral and tricuspid valves. The child had acute general tuberculosis, and died with tubercular meningitis. 7. The heart and aorta from a man aged eighteen years, who died in St. Bartholomew's Hospital with Bright's disease and pericarditis. The right side of the heart and the mitral valve were normal. Just below the aortic valves was a thickened ring of fibrous tissue, attached on one side to the septum ventriculorum, and on the other to the outer wall of the heart. Above this ring the aortic valves were competent, and of normal form. It was suggested that this ring, which had a diameter of one-third of an inch, might be due to an imperfectly developed second tier of aortic valves, formed from the original endocardium, like the numerous rows of aortic valves in the ganoid fishes. At the root of the innominate artery there was a circular opening, one inch in diameter, which led into an aneurismal cavity partly filled with laminated fibrin. The contents of the sac had dissected between the layers of the pericardium, and formed a mass, two inches by two inches and a half, resting on the base of the heart, pressing upon the pericardial veins, and causing an enormous serous effusion which stretched the pericardium across the whole front of the chest. The patient had had an illness, which might have been acute rheumatism, nine years before his death. Most cases of malformation of the heart and aorta are due to either endocarditis or congenital variation. This example was interesting as illustrating a result of variation in its double row of structures around the aorta, and a result of acute endarteritis in its aneurism.—Dr. PAYNE said that Dr. N. Moore's last case reminded him of a case of his own. Some years ago he brought a heart to the Society which he then thought presented a rudimentary additional series of aortic valves. But a committee appointed to examine the specimen reported that they were not valves at all, but only thickenings of the endocardium; and he (Dr. Payne) was sure they were right; and he had since seen transitional forms of endocardial thickening.—Dr. PYE SMITH asked if the fibrous ring was not rather to be ascribed to a persistence of the foetal constriction between the bulbus aortae and the ventricle. This had been described, and he thought it more probable that Dr. Norman Moore's specimen was an example of it than of a reappearance of a structure for which they had to go so far back as to ganoid fishes.—Dr. S. WILKS said that aneurisms in children were very interesting; they had been clearly shown to be due to embolism. The aneurism was no doubt formed at the exact spot of the embolus and not above it, and it had been suggested that in cases of ulcerative endocarditis emboli containing micrococci might cause an inflammatory softening of the artery. Older physicians, such as Addison, had recognised a connection between rheumatism and aneurism. He further asked whether Dr. Norman Moore knew of the cause of the duodenal ulcers.—Dr. NORMAN MOORE said he did not know of any special cause. All the valves of the heart referred to by Dr. Payne were quite free from disease, and he thought it would be rash to ascribe the thickening to an endocarditis so severe as to cause this, but which did not implicate the aortic valves.

A committee consisting of Drs. Payne, Pye Smith, and Coupland was requested to examine the heart.

Mr. BOWLBY showed two specimens of Obturator Hernia taken from a woman aged sixty-nine, married, mother of three children, very thin, with no history of abdominal obstruction. On June 4th she was suddenly taken with great pain

in the abdomen, collapse, vomiting, and constipation; four days later she was admitted to St. Bartholomew's Hospital with distinct signs of intestinal obstruction. No distinct local tenderness could be made out; vaginal and rectal examinations gave no assistance. Two days later there was pain in the inner and back part of the thigh, which she said she had been subject to from chronic rheumatoid arthritis. She died on the eleventh day of her illness. At the autopsy there was found a strangulated hernia on the right side, and an empty hernial sac on the left side. The hernia on each side passed over the external obturator muscle; on the right side the nerve and artery were stretched over the upper part of the sac. The right sac contained a coil of intestine adherent to the sac; there was no fluid in the sac. On the left side the sac was not so large as a walnut; on this side the obturator artery passed under the sac and divided into two beneath it, one division passing on each side of the sac. The patient was of the sex, age, and emaciated appearance common in cases of obturator hernia. The distribution of the arteries was important, but appeared to be various. In the last case at St. Bartholomew's Hospital, occurring thirty years ago, recorded by Mr. Stanley, the artery lay in front of the sac; in another specimen in St. Bartholomew's Museum the artery was on the inner side; the position of the nerve in front was constant. The intestine had been said to be drawn out into diverticula in cases of obturator hernia, but that was not so in this case. Double obturator hernia had been not rarely described, and the co-existence of other herniae was not infrequent. In most of the cases the strangulation had not been very acute; in this case the gut was, even after eleven days, not gangrenous, nor very intensely congested. In one case the constriction lasted twenty-one days before death occurred. In Stanley's case, as in this, the gut was adherent to the sac. He thought the indication was, after diagnosing the case, to cut down and expose the hernial sac, and then to open the sac, divide its neck, and return the congested contents.

Dr. BEDFORD FENWICK showed a specimen of Tricuspid Stenosis from a woman aged thirty, who had rheumatic fever at fifteen, and afterwards suffered from winter cough and dyspnoea; she went on from bad to worse till admitted into the London Hospital under Dr. S. Fenwick; there was marked distension of jugular veins but no cyanosis, cardiac dulness very wide to the right, a well-marked pre-systolic apex thrill and pre-systolic and systolic apex murmurs; proceeding to the right another pre-systolic and systolic murmur was detected. At the post-mortem both auricles, but especially the right, were very much dilated, the ventricles small. The tricuspid and mitral valves were greatly thickened, shortened, and agglutinated together, causing marked stenosis. All the organs were congested. The spleen was during life tender to pressure and pulsated. Cases of this kind were now known not to be very rare. Since his table of forty-six cases he had been able to collect twenty-three more cases, twenty of whom were females averaging in age 31.7 years. In every case the mitral valve had been more changed than the tricuspid, and in all cases the general health had been good; the great dilatation of the right auricle caused increase of cardiac dulness to the right, and afforded a means of diagnosis.

Dr. NORMAN MOORE showed the heart of a man, aged twenty-two, with Tricuspid Stenosis and Disease of Mitral and Aortic Valves; the right auricle was enormously dilated. He remarked that tricuspid stenosis was very often associated with pericarditis, and this prevents the diagnosis of distension of the right auricle. In this case the veins of the neck were not abnormal in any way. The loud systolic and pre-systolic murmur were loudest at the apex with a pre-systolic thrill at the same place. There was pericardial effusion. In seven out of fifteen cases at St. Bartholomew's tricuspid disease had been associated with pericarditis as if the valve were only affected by very severe endocarditis associated with pericarditis. Dr. WILKS asked if Dr. Fenwick thought that the tricuspid and mitral valves were affected simultaneously or successively. Dr. FENWICK said that in two or three cases it appeared clear that the mitral disease was primary, and the tricuspid disease succeeded. In more than half the cases there was a well-marked history of rheumatism.

Mr. ALBAN DOLAN exhibited some preparations showing the relations of Cystis in the Broad Ligaments, whilst still young and minute, to neighbouring structures. A parovarium, with the posterior layer of broad ligament dissected

away so as to expose its tubes, was demonstrated; Gaertner's duct appeared like a small nerve running a straight course towards the uterus. Cysts springing from the vertical tubes of the parovarium are multilocular, and bear papillary contents lined with epithelium, which may be ciliated, but is often made up of cubical cells not bearing cilia. The normal epithelial lining of the parovarian tubes is not invariably ciliated, and if so, often tends to degenerate into its original cubical form. The outer end of the horizontal tube of the parovarium generally bears a small cyst, the lining of which resembles endothelium. Between the parovarium and the Fallopian tube, small cysts, lined with endothelium, are very common. It is these, or the terminal cyst of the parovarium, that form the starting point of the so-called "parovarian cyst," which is thin-walled, unilocular, and filled with clear fluid, but no papillary growths. There is no evidence that any of these cysts spring from the Fallopian tube, the terminal "hydatid" of which never attains large proportions. The multilocular papillary cysts of the hilum of the ovary, and of the neighbourhood of Gaertner's duct, are identical with those arising from the vertical tubes of the parovarium, all these structures containing relics of the Wolffian body, the source of cysts of this kind.

Mr. HUTCHINSON showed, as a living specimen, a man who had lost the ends of nearly all the digits of his hands. The gangrene was brought on from exposure to cold. He was at work on a snowy night, and afterwards the ends of his fingers inflamed and became gangrenous; they have never recovered, for on any change of temperature they swell and become oedematous. The toes were not affected. There was a threatening of gangrene of the ears. Before this occurred, on any exposure to cold his fingers would "die" very readily. It was a case of peculiar constitutional weakness of circulation with liability to gangrene, and differing from common cases of frostbite in the slight intensity of the cold causing the death of the parts.—Dr. WILKS said he had a boy in the hospital last year with gangrene of fingers, ears, and toes, and hæmaturia. All had healed up. The hæmaturia pointed to some blood condition.

Dr. S. WEST showed a specimen of Mediastinal Tumour from a boy aged fifteen, who had been ill for only two months. For three weeks he had a swelling in front of the chest, with brassy cough and dyspnoea, and pain down the side of the chest, and inner side of the left arm. After a few days in hospital the swelling increased and appeared above the sternum. A needle was inserted, but nothing was obtained. A day before his death the left pulse was found unequal. He died in an attack of dyspnoea. At the autopsy the tumour was found to be very large and growing from the mediastinal glands, pressing upon and over the heart, flattening it down against the diaphragm. The vessels and nerves on the left side were quite embedded in the tumour, but were all free on the right side. The only secondary growths were in the kidneys, but the primary growths had extended down to both front and back of the heart, under the pericardium, without implicating the muscular tissue. The growth was a small round-celled sarcoma. The nerves in the tumour were found to be greatly thickened, owing to infiltration with tumour tissue. The case was interesting on account of the age of the patient; out of fifty-five similar cases only five occurred between ten and twenty years of age. Dr. Douglas Powell had given the average age as twenty-four. The whole mass had also grown with extreme rapidity; the shortest time given by Walsh was three months and a half. He had never seen the nerves thus thickened; but Dr. Quain had recorded a case in which thickening was due, however, to inflammation, and not to infiltration of the tumour. Dr. S. WEST also showed two specimens of Perforating Ulcers of the Large Intestine from Typhoid Fever. In both cases the disease was of long duration, and in both there were cicatrices of typhoid ulcers in the ileum. In one the patient died suddenly, with signs of peritonitis, and after death a collection of puriform fluid was found in the pelvis, and a perforation of the lower end of the sigmoid flexure. In the other the liver and intestines were found matted together in the right hypochondrium, where a collection of pus was found, and a perforation of the colon at the junction of its ascending and transverse portions. In this case the fever ran a mild course throughout; but there was all along one symptom which he had always observed to be attended with a fatal termination to the case—a scarcely audible first sound of the heart.

Dr. HENEAGE GIBBES showed microscopical sections of a specimen of Cirrhosis of the Liver in a child of seven months, following congenital absence of the common bile duct. The case was under the care of Dr. Steel of Abergavenny. A male infant, eighth child of healthy parents, born December 3rd, 1881, first began to show symptoms of jaundice a few days after birth; was treated with castor oil in mild doses, afterwards with iridin in doses of two to three grains thrice daily. This seemed to have a slight effect on the stools and skin; other remedies had also been tried without any result. Nutrition was maintained tolerably well till the sixth month, when wasting and ascites set in, and the child died on the 10th of July. The liver was found to be hard and smooth, and weighed four ounces after hardening in spirit. No common duct could be found in connexion with the duodenum. Under the microscope dense bunches of fibrous tissue were found between the lobules, in the interstices of which were the dilated bile ducts filled with bile. The cells in the lobules seemed broken down, and did not stain. This seemed to be a case of cirrhosis following on congenital absence of the common duct. The jaundice not appearing for the first few days might be explained by the small amount secreted at that early stage having filled the diverticula of the bile ducts. After these were fully distended jaundice would be set up.

The Society then adjourned.

## CLINICAL SOCIETY OF LONDON.

### *Treatment of Phthisis by Residence at High Altitudes.— Excision of Cancer of the Tonsil.*

THE first meeting of the present session of this Society was held on Friday, Oct. 13th, J. Lister, Esq., F.R.S., in the chair. The new volume of the Transactions was stated to be ready for distribution, which is a fact very creditable to the hon. secretaries. The President read the new rules in reference to the exhibition of living specimens. He also showed the form of diploma of hon. membership, and stated that most of the hon. members recently elected had expressed in warm language their sense of the honour thus conferred upon them.

Dr. THEODORE WILLIAMS communicated a case of Phthisis treated by Residence at High Altitudes, the patient having been exhibited at a former meeting of the Society. A medical man aged thirty had cough and expectoration of three years' standing, followed by hæmoptysis, wasting, elevation of temperature, and great prostration; and when seen by Dr. Williams in consultation with Dr. Verker Benden, on Aug. 30th, 1881, he presented the physical signs of consolidation of the upper lobe of the left lung. After five months' residence at Davos, including a walking tour of seventeen days in the Engadine, during the whole of which period he took exercise largely, he gained a stone in weight, and found his strength and power of climbing greatly improved. On first arriving at Davos he had dyspnoea from the rarefaction of the air, but this passed off, and his respiratory powers became greater than previously. On his return, Dr. Williams found an increase in the cyrtometric and other chest measurements, especially in the upper regions of the thorax; and the physical signs denoted the development of emphysema around the old consolidation and hypertrophy of the healthy lung. Dr. Williams stated that while he ascribed the general improvement of the patient to the dry form of antiseptic atmosphere and the sun's powerful influence, he assigned the arrest of the tubercular changes to the local effects on the lungs of breathing rarefied air, which by inducing emphysema caused an expansion of the thorax, at the same time opposing a barrier to the encroachment of further infective processes in these organs. With regard to the durability of the good results of mountain climates, Dr. Williams's experience was that in well-selected cases one or two winters sufficed to produce permanent arrest of consumptive disease, though in many instances a prolonged stay of at least two years was desirable. Dr. Williams exhibited cyrtometric tracings of similar cases that had resided at Davos and Colorado for several months to illustrate the

widening of the chest through breathing mountain air.—Dr. ALTHAUS was much interested in this subject, as he had recently sent a case of advanced phthisis to Colorado, and the improvement that had followed was most marked. The patient referred to was a young lady with a cavity in one lung, hectic, and great wasting. All European climates had proved ineffectual; but after being at Colorado (8000 feet above the sea) a week, there was a marked change in her state, and she was able to be out in the open air all day long. Patients were able to stay in Colorado all the year round; the weather was so fine that there was no need to send them into the lower levels at any time; the air was extremely dry. A residence of two years was considered desirable by Drs. Solly and Norman, who resided there, and with whom he had been in correspondence on the subject.—Dr. BROADBENT could not quite see the point of the paper. Such a case as that related was not an infrequent experience, and the change noted was such as was often observed after residence in any of the usual winter resorts. He wanted to know whether in a large number of cases the results were better from residence at high altitudes than from residence in the south of France or Egypt.—Dr. MACLAGAN asked how far the arrest of the disease was due to residence in a germless atmosphere, such as was known to exist in such high altitudes, and how far to the general healthiness of the life at Davos. How far also was the enlargement of the chest peculiar to cure of a case of phthisis, or common to anyone moving to such a latitude.—Mr. LISTER said that Dr. Williams's case was an example of improvement under many favourable conditions. If high altitudes were useful, it was important to know how the good effects were brought about. If the air was germless or aseptic, he failed to see how that circumstance could interfere with the organisations already present in the lung. Possibly the absence of dust in the air might be one cause of the beneficial result. He had recently himself experienced in high altitudes an unsatisfied desire for taking deep inspirations, and this must after a time cause enlargement of the chest. But he asked whether there was any benefit in this; the deeper breaths were merely efforts to take in the same amount of oxygen as in lower altitudes. But how far was this desirable? If it remained permanent, on returning to the lower levels of course it would be useful. Residence in these high altitudes certainly did exercise a beneficial influence.—Dr. WILBERFORCE SMITH remarked that a very small gain of flesh makes a great difference in the measurement of the chest. He suggested that an aseptic atmosphere might prevent the intercurrent inflammatory attacks which increase the phthisical state.—Dr. WILLIAMS, in reply, referred to his paper in the International Congress Transactions. In reply to Dr. Broadbent, he said that as a specialty of mountain climate he found he got expansion of the chest and change in the percussion note from dulness to resonance to hyper-resonance. In this respect this treatment differed in its effects from sea voyages, or residence in Egypt or the Cape. He was not himself sure that the air at Davos was germless; the air had never been analysed. He thought the expansion of the chest was a distinct advantage; he also suggested that in these patients the lungs were often not fully developed, and residence at these high altitudes caused an enormous development of the lung. Almost all the natives of high regions have large lungs. He did not think Davos and such places were very successful in staving off intercurrent inflammations.

Mr. GOLDING BIRD detailed a case in which he had removed an Epitheliomatous Tonsil in the manner adopted by Cheever (1871), and referred to three other cases of the same disease in which he had determined not to operate. The operation consisted in an external incision from the ear to the hyoid bone, through which the wall of the pharynx was reached with the greatest ease, and the tonsil with the adjacent pharyngeal tissue removed with the galvanic cautery. The later stages of the operation were aided by an additional incision through the cheek from the angle of the mouth. The disease having also affected the tongue, part of that organ was removed as well as an enlarged gland at the angle of the jaw. Until the wound closed an œsophagus tube was used for feeding, and though great relief was given to the patient, yet he soon succumbed to recurrence, not in the site of the excised organ, but in the tongue and in the lymphatics of the neck. The conclusions arrived at by the author were that where only a limited infection of the

lymphatic glands existed, and where the faucial growth was circumscribed, or nearly so, operation was called for; but that in other cases feeding with tubes with subsequently gastrostomy was the treatment. The operation was itself far easier than many of daily occurrence, and seemed to offer no special risk to the patient. Of the four cases mentioned it was considered by Mr. Golding Bird that the disease was primary in the tonsil in three, in all four it was the left side that suffered.

Mr. CLEMENT LUCAS related a case of Excision of the Base of the Tongue, Right Tonsil, and part of the Left Palate for Epithelioma. The patient, aged sixty-four, a coalporter on the riverside, who had drunk freely, first came under Mr. Lucas's care in Guy's Hospital on Feb. 13th, 1890. He was at that time suffering from a large aneurism of the right popliteal artery, causing pain and œdema of the leg and foot, and from a smaller aneurism of the left popliteal. Digital compression of the right femoral artery was commenced on Feb. 17th, and continued for sixteen hours, when the aneurism appeared to have consolidated, and pulsation could no longer be detected. On the following day some pulsation was re-established, and on the 20th digital compression was again commenced, and continued for eleven and a half hours, when pulsation ceased and did not recur, the tumour afterwards gradually shrinking. An attempt was made about a fortnight later to cure the small aneurism in the left popliteal space by digital compression, but this failed, and as the tumour caused him little inconvenience, no further treatment was suggested, and he left the hospital. He was readmitted on August 2nd, 1891, suffering from epithelioma of the base of the tongue and right tonsil. On the right side of the tongue, opposite the last molar teeth, was a small ulcer, grey in colour, and irregular on the surface. The ulceration extended along the anterior pillar of the fauces, and involved the right tonsil as well as the tissue between the tongue and the jaw. The surface of the tongue near the base was raised and indurated for about half an inch from the margin of the ulcer. The movements of his tongue were interfered with, so that mastication and deglutition were painful, and there was an increase of salivary secretion. No enlarged glands were felt beneath or behind the jaw. The operation was performed on August 9th. The patient being placed under the influence of chloroform, the cheek was first divided by an incision from the angle of the mouth to the masseter muscle, and the facial artery was twisted. A gag was then inserted on the left side of the mouth whilst the tongue was drawn forward with forceps, and the flaps of the cheek were held back by retractors. The back of the tongue and tonsil were in this way easily reached. The soft palate was next divided near the middle line by means of Paquelin's cautery, and dissected down with the anterior pillar and the tonsil. Attention was now paid to the tongue, which was divided in the median line with a scalpel, and carefully dissected outwards till the lingual artery was reached. This was seized with two pairs of torsion forceps, divided between, and the ends twisted without loss of blood. The tissue between the tongue and jaw was next dissected up, the cautery being used to stop any bleeding points, and finally the growth, with the base of the tongue, right tonsil, and half the soft palate, was removed in one mass. The cheek was brought together with three harelip pins, and it united primarily. The patient recovered rapidly after the operation, and sixteen days later was again subjected to digital compression for the cure of the left popliteal aneurism, which was about the size of a pigeon's egg. Pressure was kept up with the aid of opium for forty-eight hours, but soon after this, though much consolidated, the tumour still pulsated. He left the hospital, with the tongue quite healed, on September 16th. He was readmitted into the hospital on February 13th, 1892. There was no return of the disease in the tongue or palate, which were united by a firm and sound cicatrix. There was a large mass on the right side of his neck below and behind the jaw, which commenced six weeks before, and grew rapidly, extending outwards beneath the sterno-mastoid. An operation for the removal of this growth was undertaken on the following day. A vertical incision about four inches in length was made, commencing behind the jaw, and the growth dissected round. It was found necessary afterwards to enlarge the wound transversely. In the course of the operation the lower part of the parotid gland, a portion of the sterno-mastoid, the posterior belly of the digastric and stylo-hyoid, and a portion of the submaxillary gland were removed, all of which were infiltrated. The facial artery was twisted,

and the facial and lingual veins ligatured with catgut. At the bottom of the wound the internal jugular vein and the two carotids, with the hypoglossal nerve, were exposed. Two enlarged glands were also removed from beneath the sterno-mastoid. The patient recovered without a bad symptom, and left the hospital on March 24th. He was again seen in July last with a recurrence of the growth on both sides of the neck, but there was still no sign of disease in the original site. It was not then thought advisable to interfere further. Mr. Lucas said that, by the operation described, it was evident a cancerous tonsil, with the adjacent structures, can be completely removed from within the mouth, and when this was practicable, it had the advantage over the external operation of avoiding the fistulous track, through which saliva was apt to ooze. For the rest, the treatment of cancer here did not differ from the treatment of it elsewhere. The treatment—and the only treatment—was to operate early, and to operate late; to operate, indeed, so long as it was possible to remove a loathsome outgrowth without great immediate danger; to operate to keep it local; to operate on the earliest return; and though we might often be disappointed in our attempts to eradicate the disease, we might still prolong life, or, as in the case before us, succeed in driving the disease from its original site to one where it was less offensive, and more easy for the patient to bear.

Mr. C. HEATH congratulated Mr. Golding Bird and Mr. Lucas on their bold procedure. Dr. Cheever's operation must of necessity be of great difficulty, but was successful in his and Mr. Golding Bird's hands. But the question arose as to whether good was done by such an operation. His own view was that, whenever the surgeon can get beyond the cancerous disease, an operation was justifiable, even when the growth was in the lymphatic gland; but the opinion was often given by eminent surgeons that cancerous disease of lymphatic glands was a bar to operation. He should therefore be glad to know what the general opinion was.—Mr. MORRANT BAKER thought that Mr. Lucas was very successful in the long period that elapsed without local recurrence. He asked if the part was removed with the écraseur, or with the scissors, after Mr. Whitehead's method. He had himself used in many cases the écraseur, to prevent hæmorrhage and lessen pain. He quite concurred with Mr. Heath in advocating the removal of cancerous lymphatic glands where they could be completely removed.—Mr. BUTLIN thought removal of the tonsil through a deep wound on the neck was hardly worth doing, although possibly justifiable. Cheever had had two cases, and Czermak had had one, but in all there was rapid recurrence. As a result of his researches, he found that the only case of malignant disease of the tonsil really improved by operation was one of lympho-sarcoma, removed through the mouth, in which there was freedom from recurrence for two years at least; and he rather doubted whether there was not some error in the diagnosis in this case, as it was extremely difficult to distinguish a lympho-sarcoma from an ordinary enlargement of the tonsil.—Mr. LISTER said there was no doubt of the boldness and skill of the operators in the cases related. But he feared that, on the average, operative interference was more likely to be harmful than beneficial. Mr. Lucas's case was very successful and favourable. He asked for a more detailed account of the last step of this operation. He was glad to know that surgeons now generally removed cancerous lymphatic glands when accessible; this was quite a change since he was a student. He believed he was the first person to clear out an axilla in cases of scirrhus of the mamma, and he had had reason to be very well pleased with his results. In a case of epithelioma of the lip and a single enlarged gland under the chin Mr. Syme used to operate, and with good results, although at the time he deprecated such operations where glands were affected in other situations.—Mr. GOLDING BIRD'S opinion was distinctly in favour of not operating in cases of cancer of the tonsil.—Mr. CLEMENT LUCAS said that in his case the tongue was divided entirely with the knife. The soft palate and tonsil were first dissected down, then the tongue was dissected up, and the mass to be removed was carefully divided, and any bleeding point was touched with a Paquelin's cautery. He thought his case showed that such operations were not hopeless, for he had freed the man from the loathsome disease in the mouth, and he was now suffering from a far more tolerable affection in the neck.

The Society then adjourned

## OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

*Chronic Membranous Inflammation of Conjunctiva.—Chronic Tubercle of the Choroid and Brain.—Miliary Tubercle of the Choroid and Lung without Meningitis.—Large Tubercle growing near the Optic Disc.—Destructive Ophthalmitis in Children.*

THIS Society met for the first time this session on October 12th, Mr. W. Bowman, F.R.S., President, in the chair. The President laid on the table a copy of the Society's Transactions, vol. ii.

Mr. ANDERSON CRITCHETT and Mr. JULER showed a case of Rare Affection of the Conjunctiva, which they considered to be one of chronic membranous or so-called "diphtheritic" conjunctivitis. The patient was a young woman aged seventeen. Ten months ago she had local suppurating (soft) sores on the vulva and anus, for which she was treated at the Lock Hospital. There were no symptoms of constitutional syphilis. No mercury was given, and she was discharged cured in two months. Five months ago she had an attack of what appeared to be inflammation of the ocular conjunctiva in both eyes. This was treated first with alum and then with zinc lotions, and was almost cured when a white patch appeared in the left eye near the lower cul-de-sac. It was a white, opaque, non-vascular, diphtheritic-looking growth, unattended by pain and without suppuration. Since that time it has gradually extended and now appears as a dirty-white shreddy mass, seated on a semi-indurated vascular base of the conjunctiva. The lower part of the ocular conjunctiva, the lower cul-de-sac, and the inner surface of the lower lid are the parts now attacked. Ten days ago the right eye became similarly affected, a white patch appearing in the lower part of the ocular conjunctiva surrounded by vascular injection. It is now (10th day) about 1.5 centimetres in length and 0.5 centimetres in width, situated horizontally between the cornea and the lower cul-de-sac. The cornea is clear and the vision normal. There is no suppuration and only slight pain and photophobia; iodoform lotion, quinine lotion, &c., have been applied, and mercury given internally without any improvement.—Mr. POWER remembered a similar case in a man thirty years old who had a growth at the lower part of the outer conjunctiva. The growth increased, and eventually projected as a horny mass from the surface of the cornea. The eye was excised.—Mr. NETTLESHIP saw about two years ago a girl with a patch of adherent membrane on an infiltrated base on the ocular conjunctiva, which had lasted about six or seven weeks when she was first seen. There was no surrounding inflammation, and he regarded it as a localised chronic diphtheritic patch. He touched it with lapis divinus several times, and it disappeared, leaving a scar. Other cases of chronic diphtheritic conjunctivitis had been published, one by Dr. Businelli of Rome, where masses of membrane kept reforming and protruding between the lids. Another case is recorded by Mr. Mason of Bath, and others by Mr. Hulme and Mr. Hutchinson. It, therefore, seemed as if in certain cases diphtheritic conjunctivitis tended to become chronic.—Mr. POWER added that in his case there was a distinct specific history.

Dr. S. WEST showed a case of Leucocythæmia with Retinal Changes (dilated veins, &c.)

Dr. S. MACKENZIE read notes of a case of Chronic Tubercle of the Choroid and Brain. The disease occurred in a girl aged fourteen. There was no tubercular history. She had never been well since she had whooping-cough, eighteen months before her death, suffering from frontal headache, feverish attacks, diarrhoea, and occasional vomiting, and loss of appetite and flesh. Following this was white swelling of the right knee. She then rapidly lost sight, whilst the other symptoms continued. When first observed she was flushed and feverish; there were no abnormal signs in chest or abdomen. She was quite blind. Ophthalmoscopic examination showed double papillitis. In the left eye there was a patch of choroidal disease, larger than the disc, to the outer side of it. It was opaque and yellow in the centre, with a zone of black pigment, and an outer margin of pigment. A smaller circular patch was below the disc, over which coursed retinal vessels. One small patch existed in the right eye. The diagnosis was chronic tubercle of choroid and brain.

Later acute cerebral symptoms made their appearance, with high temperature, and terminating in death; these were thought to indicate acute tubercular meningitis. The head only was allowed to be examined at the necropsy, when acute tubercular meningitis, with several caseous tumours in various parts of the brain, were found. Microscopic examination of them showed aggregated tubercle with giant cells. The choroid was thickened owing to the presence of tubercles with giant cells. The retina was swollen, and the optic nerve and its sheath showed marked signs of inflammation. The brain tumours and tubercular choroid were examined for bacilli by the processes of Ehrlich and Heneage Gibbes with negative results. It was remarked that the detection of the tubercular disease in the choroid was of some value in aiding the diagnosis as to the nature of a coexisting encephalic lesion; but, unfortunately, owing to the kind of disease, this knowledge was of little service in treatment. That some intracranial disease was present was indicated by the double papillitis, headache, occasional vomiting, drowsiness, &c., and that it was tubercular by the age of the patient, the feverish attacks, the diarrhoea, wasting, and white swelling. Allusion was made to Deutschmann's inoculation experiments in rabbits, in which it was shown that the tuberculous induced in the membranes and brain was followed by double papillitis and tubercle of the vitreous and choroid, and that the process was traced in post-mortem examinations to metastatic infection along the optic nerve sheaths. Deutschmann has also recorded a case of tubercular meningitis in a child in which an appearance of tubercle in the optic nerve sheath was present. The present case lent no support to this connexion between the tuberculosis of brain and eye. Attention was drawn to the similarity of the changes in the eye and brain in showing us pathological processes as well as aiding in diagnosis.

Dr. WARNER read notes of a case of General Miliary Tuberculosis; tubercle in choroid; no meningitis. The patient was a girl nine years of age. She presented continued fever and emaciation; respiration was increased in frequency out of proportion to the pulse and temperature; this averaged  $102^{\circ}$  to  $103^{\circ}$ . There were crepitations over the lungs, but no signs of pneumonia. The optic discs appeared healthy, but in either eye there were three or four light-coloured raised cloudy spots, at some points turning aside a retinal vessel. The child died eight days after these tubercles were first seen. At the post-mortem the lungs were found crowded with tubercles, others were found in the liver, spleen, and kidneys. There was no meningitis. The back of either eyeball being removed, tubercles were found in the choroids. The case was put forward as an illustration of the association of tubercles in the choroids as a part of the general miliary tuberculosis without meningitis.

Dr. BRAILEY communicated a case where a Tuberculous Mass, apparently primary, springing from the optic disc and immediately surrounding the choroid, simulated in some of its clinical features a glioma. The globe was enlarged and its tension increased; the cornea was increased in size, and the anterior chamber was deepened; the retina was detached except from the ora serrata; and it was this membrane that was visible during life, with its vessels, through the clear lens. There were many point-like posterior synechiæ. Though the mass, which presented all the histological evidences of tubercle, replaced the tissue of the papilla, it did not extend backward beyond the lamina cribrosa, nor laterally for any distance in the choroid. As there was no precise microscopical evidence that it had originated in the retina or tissue of the papilla, the author presumed that a choroidal origin was the most likely in view of the number of cases of tubercular choroidal disease that had been described. The patient, a boy aged two, the second child, was stout and well, but had been within a few months very thin and weak. The eldest was four years of age. Before this there had been a miscarriage at four months. The mother died of consumption six months before the excision. The father was said to be healthy. The after history of the patient could not be traced.—Dr. BAXTER said that during the last twelve years he had examined the eyes in a very large number of cases of tubercular meningitis, and in no instance did he find tubercle of the choroid, although optic papillitis was often found. In the only two cases which he had seen it was associated with very abundant tuberculosis in other organs.—Dr. COUPLAND said that although meningitis was present in every case in which he had found choroidal tubercle (about six in all), yet in these cases the tuberculosis was more or less general. The eyes, however,

were seldom examined post mortem, except in cases of cerebral disease, and Cohnheim's statement as to the frequency with which choroidal tubercle occurred in subjects of tubercular phthisis apart from meningeal tubercle had never been contested.—Dr. SHARKEY during a period of three years and a half had examined every case of tubercular meningitis at St. Thomas's Hospital, and had only once found choroidal tubercle, which was confirmed on post-mortem examination. No case of tuberculosis was examined that did not present cerebral symptoms.—Dr. BARLOW thought it was premature to make any general assertion as to the infrequency with which choroidal tubercle and tubercular meningitis coexist; and that the absence of choroidal tubercle in any given case of tubercular meningitis ought not to be assumed on ophthalmoscopic evidence alone without an examination of the back of the eye post mortem. He had seen about twenty cases of choroidal tubercle post mortem, and of these a large number were associated with miliary tubercle in the pia mater. He had notes of thirteen in which there was this coexistence, and believed there were more. A very fine dappled appearance of parts of the fundus is sometimes seen with the ophthalmoscope in cases of tubercular meningitis, and in two such cases he had found post-mortem that it corresponded with some very minute tubercular spots associated with ordinary nodules of miliary choroidal tubercle. He thought that to such a lesion might perhaps be applied the term "tubercular dust," which was used by Barthé and Rilliet in regard to a form of tubercle seen sometimes in the liver. In regard to Dr. Mackenzie's case, Dr. Barlow thought it was of importance as bringing before us the possible chronicity of choroidal tubercle. Dr. Barlow had had under his own care, about four years ago, a boy with a diffuse general massive infiltration of one choroid, which proved, on microscopic examination by Mr. Nettleship, to be indistinguishable from caseous tubercle. The eyeball was removed, and thirteen months afterwards, when the boy died, several tumours of caseous tubercle were found in the brain. Thus it would appear that in the choroid, as in other organs, several forms of tubercular deposit might be found, and possibly the one to which he had referred might be compared with a mass of caseous pneumonia in the lungs.—Dr. SANSOM raised the question of the prognostic value of the detection of choroidal tubercle, which he had met with not only in cases of meningitis, but also in cases of ordinary phthisis. But on one occasion he was led to give a most unfavourable prognosis in a case of meningitis from finding in the fundus what seemed to him an unmistakable tubercle of the choroid. He subsequently learnt that the patient recovered, and this fact had shaken his confidence in the importance of choroidal tubercle in prognosis.—Mr. HULKE had for some years past examined the eyes in cases of meningitis, and could confirm Dr. Baxter's statement that optic papillitis was often met with, but choroidal tubercle (except as part of general tuberculosis) very seldom.—Mr. B. CARTER remarked that several years ago he had opportunities of examining ophthalmoscopically a large number of cases of meningitis. Like Mr. Hulke, he met with in some cases a swelling or inflammation of the disc, and in cases too when the diagnosis was otherwise doubtful, but he never met with anything that he took to be choroidal tubercle. From his subsequent hospital experience he had met with choroidal tubercle in cases of general tuberculosis, but not in meningitis; he had also seen appearances simulating tubercle, and he thought its ophthalmoscopic diagnosis rested on an insecure basis.

Mr. NETTLESHIP read a paper on Certain Cases of Destructive Ophthalmitis in Children. The chief object of the paper was to draw attention to the cases of deep-seated disease which more or less simulate glioma of the retina in their clinical features. The author believed that there were two principal types of morbid change in this class of cases—(1) irido-choroiditis, either acute and almost purulent or chronic, the result of either form being inflammation and opacity in the vitreous, with subsequent detachment of the retina and backward displacement of the ciliary processes by shrinking of the inflammatory material; hæmorrhage between choroid and retina might occur; (2) inflammation and condensation of the vitreous, especially in its outer layers, and in some cases also in its antero-posterior axis, probably the result of a chronic severe retinitis, no detachment of retina occurring. Iritis occurred in nearly all cases of "pseudo-glioma," and there was often severe inflammation of the eye in the early period of the case. It was par-

ticularly as to the causes of these eye changes that information was wanted. It was not sufficiently known that the conditions called pseudo-glioma, whether following severe inflammation of the eye or not, often came on during or soon after some severe illness, whilst in a considerable number the children were syphilitic. Measles, whooping-cough, varicella, and perhaps pyæmia and sporadic recoverable meningitis, appeared from the cases, published and unpublished, collected by the author, to be the commonest antecedents of these eye changes. He asked especially for evidence as to the nature of the communication between the ocular and the constitutional conditions. — Dr. BARLOW could recall five of these cases, and in three of them there was reason to suspect the existence of congenital syphilis. But he had not been able to realise their direct connexion with that diathesis. He thought the most likely hypothesis was that some of them, at all events, were pyæmic. He had had no opportunity of examining a case post mortem. The nearest approach to the condition described which he had been able to examine post mortem was the eye of an adult patient of his, who had ulcerative endocarditis and basic meningitis. This eye presented extensive small retinal hæmorrhages, and opacity of the vitreous, but no suppuration. During life there had been very slight steaminess of the cornea, and some iritis. Whatever the nature of the process, he thought it must begin from behind and come forwards, and that these cases might perhaps only differ in degree from those of panophthalmitis of embolic origin. With the account after general symptoms which Mr. Nettleship had given Dr. Barlow quite agreed. So far as he remembered, in most of the cases there was a history pointing to the probability of a cerebral attack, most likely meningeal. This had lasted for a time, and then came to an end, the definitive character of the brain symptoms being a special feature. In two cases he remembered the children had remained semi-idiotic, and with a certain limpness about the muscles of the neck, so that they were unable to sit up. But the active signs of brain trouble had come to an end as well as the eye lesions. — Dr. BRAILEY said that he had examined an eye which had been excised for suppuration in ulcerative endocarditis. There was much pus between the choroid and retina, and in that it differed from "pseudo-glioma." In many cases the retina is detached, with suppuration of the vitreous. Mr. Hulke first drew his attention to spontaneous suppuration of the vitreous in these cases. As to diminished tension in "pseudo-glioma" he had seen cases of intraocular hæmorrhage in which tension was increased. — Mr. WARREN TAY mentioned a case of cerebro-spinal meningitis with double panophthalmitis, and stated that Mr. Hutchinson had said that in epidemics of cerebro-spinal meningitis it was not uncommon to get this panophthalmitis. — Dr. S. MACKENZIE, who had seen a fair number of cases of sporadic cerebro-spinal meningitis, had not found this condition; but double optic neuritis. — Mr. B. CARTER referred to an exhaustive report on Epidemic Cerebro-spinal Meningitis by Hirsch, which he had translated for the Epidemiological Society's Transactions. — Dr. FITZGERALD remembered an epidemic of this disease (cerebro-spinal meningitis) in Dublin, and at least one case in which the eyes were destroyed. Since then he had seen cases of panophthalmitis in other affections — e.g., puerperal fever, and in a case of pyæmia following amputation. He believed that Dr. Stokes had pointed out the occasional occurrence of sudden destruction of the eye in heart disease. — Mr. JAS. ADAMS pointed out that the class of cases described by Mr. Nettleship — viz., "pseudo-glioma" — differed from the embolic and pyæmic cases of destruction to the globe. In "pseudo-glioma" the cornea remains transparent, and the pathognomonic condition of the iris is plainly to be seen. He had at present under observation one of these cases, in which the vitreous is undergoing remarkable changes. As there is no object in excising the globe in such cases, it would be interesting to learn what changes may take place in the affection when left to run its course.

## MEDICAL SOCIETY OF LONDON.

### *Pathology and Treatment of Whooping-cough.*

THE first meeting of the services of this Society took place on the 16th instant, the chair being taken by the President, Mr. Francis Mason, who, in a few introductory remarks, made especial reference to the extensive alterations that were being

carried on in the Society's premises. The Fellows would remember that when he had the honour of taking the chair as President for the first time, in March last, he hinted that the Council were contemplating taking additional premises in order to provide increased accommodation for the library, as well as to add to the comfort and convenience of the Fellows. He was now happy to say that that project had been realised, and he believed that, after the completion of the work, the Society's rooms would be second to none in the metropolis. He passed a well-merited tribute to the two honorary secretaries, Mr. E. Owen and Dr. I. Owen, for the zeal displayed in the negotiations, and concluded by reminding the Fellows of the claims the Society had on their support.

Mr. DOLAN read an abstract of his essay on Whooping-cough, to which had been awarded the Fothergillian medal of the Society. Dealing with some points of its pathogeny, he expressed his dissent from the view of Guéneau de Mussey, that the malady was a bronchial adenopathy, its chief symptom being induced by pressure on the vagus by the enlarged glands, and showed that this glandular enlargement was not always present in pertussis, and further that the glands may be swollen without producing the characteristic cough. The disease, indeed, bore much resemblance to those diseases the causes of which are now believed to be minute organisms or fungi. Its highly contagious nature, period of incubation, effervescence and defervescence, its regular course, and the immunity from subsequent attacks, were grounds of analogy determining the place of pertussis in the group of diseases caused by protophytic fungi. The attempt by Linnæus to prove that all diseases were produced by animalcula, or had an insect origin, foreshadowed the conclusions now arrived at by the discoveries of Pasteur. In 1867 Poulet found bacteria in the sputa of pertussoid patients, and Letzerich had induced whooping-cough in rabbits by inoculating the trachea with sputa from the human subject. The author had repeated these experiments, and found that whilst inoculation with the blood of whooping-cough patients was without effect, that of sputa and other secretions caused death. He had found also on microscopic examination of sputa ordinary bacteroid forms, and a microbe resembling the spirochæte plicatis of Cohn. The application of special methods of staining, as employed in the detection of the bacillus tuberculosis, would no doubt reveal the special microbe of pertussis. Admitting the fungoid nature of pertussis, its contagious property was easily explained by germs being thrown off into the air and received into the body, setting up constitutional disturbances, and subsequently attacking the pulmonary epithelium, giving rise to all the phenomena of pertussis. No pathognomonic lesions could be detected on post-mortem examination, for the simple reason that whooping-cough was rarely fatal; death resulted from complications which were very numerous. As to glycosuria in whooping-cough, he had found it present in fourteen out of fifty cases. Turning to the question of treatment, he pointed out the necessity for measures of isolation in preventing the spread of the disease, for the enforcement of which measures the co-operation of all classes of the community was needed; and although the course of the disease could not be controlled by treatment, the patient could be placed in the most favourable circumstances towards recovery; certain painful and prominent sources of trouble could be relieved and complications guarded against so as to assist nature in her efforts to throw off the disease. There was no panacea or specific remedy, but if the dependence of whooping-cough upon a specific virus be the true explanation of its pathogeny, the lines on which its rational treatment and prophylaxis were to be pursued became clearer and more hopeful.

WEST HERTS MEDICAL ASSOCIATION. — The sixty-ninth meeting of the Society was held at Watford, Dr. P. Hood, president, in the chair. Dr. Iles read a paper on the period of incubation in diphtheria and in German measles occurring in the same patient. The cases quoted were interesting and important, and Dr. Iles was requested to send them to some medical paper. In the discussion which followed, Drs. Hood, Brett, Saunders, Fisher, Baltonbury, Hobson, Lemon, and others took part. Mr. A. Stradling was elected a member. Dr. Hobson of Berkhamstead will read the next paper, on "Ligature of the Brachial Artery for Wound of the Superficial Palmar Arch."

## Reviews and Notices of Books.

*Spirillum Fever (Synonyms, Famine or Relapsing Fever), as seen in Western India.* By H. VANDYKE CARTER, M.D. Lond. London: J. and A. Churchill. 1882.

THE terrible famine that ravaged the western provinces of India some five years ago was succeeded by an epidemic of fever which in its leading features was unlike any other type of fever hitherto recognised in that country. As the sick flowed into the great centres of population, the fever spread there also, and Bombay became the focus of an epidemic; its hospitals were crowded with patients, and a medical commission was soon actively engaged in studying the disease. Chief amongst these was the author of this work, who has here presented us with the results of his investigations and matured experience. Taking up the work with his characteristic thoroughness and energy, it may truly be said that he has probed the disease to the bottom, and his monograph will occupy a foremost place in literature. It is a monument of patient, prolonged, and exhaustive labour, and adds to the reputation of its author as a careful and conscientious investigator.

We have indicated that until the occurrence of this epidemic, relapsing fever was hardly known in India. This no doubt was because, as Murchison, indeed, points out (and Hirsch writes in the same sense), it had been confounded with "bilious intermittent" and other tropical fevers of malarial origin; and this or a like confusion relapsing fever probably shares with other specific fevers, modified by the climatic conditions under which they arise. There can be no question at all as to the identity between the fever described by Dr. Vandyke Carter and the relapsing or famine fever formerly so well-known nearer home. Ireland used to afford the most numerous examples of epidemics of this contagious famine fever, and Scotland and England have suffered also, but not of late years. We question whether a single case has been seen in London during the past ten years. No doubt there is great cause for congratulation in this fact, although it has prevented our home physicians from following up the remarkable discoveries which more than any other have so stimulated research into the relation between micro-organisms and specific diseases—we mean the discovery by Obermeier of Berlin (who fell a victim to his zeal) in 1873 of the spirillum in the blood of patients suffering from relapsing fever, of its occurrence during the pyretic paroxysms, and its disappearance in the apyretic interval. The peculiar form of the bacterium and its constantly observed presence in such cases soon led to the discovery being confirmed wherever opportunity offered. Such an opportunity came to Dr. Vandyke Carter and his colleagues in this Bombay epidemic; the result being that Obermeier's researches were not only confirmed, but the essential part played by the organism became so evident that, as the title of this work shows, the term "relapsing" has been thrust aside, and for it has been substituted the name by which the bacterium is denoted. It is at all times a hazardous thing to import new terms to designate well-known affections, and some may doubt the wisdom of Dr. Carter's step. For it will be long before the phrase "relapsing fever" will be universally discarded, even although, as Dr. Carter insists (and this is the strongest justification for the change he adopts), there are many cases in which the "relapsing" feature, hitherto adopted as the criterion of the disease, has been lacking, whilst the other, and on scientific grounds the sounder criterion—viz., the presence of spirillar infection—has been present. The occurrence of the spirillum as the leading and most constant feature of the disease cannot, after these researches, be gainsaid; and when to this is added the fact of

the high degree of contagiousness and the results of inoculation, which Dr. Carter and Professor Koch have successfully performed, there is left no room for doubt as to the very important part played by the spirillum in the disease.

Dr. Carter's work deals first with the history of the epidemic upon which it is based, and shows that the cases occurring in Bombay were imported or developed by contagion from these. He contrasts the prevalence of famine and the fever, and raises the interesting question whether relapsing fever may not now become endemic in Bombay as in other regions. The occurrence of cases since the epidemic and within the last twelve months is in favour of this. The clinical history of the disease is dealt with in a most exhaustive manner, first by a general summary, and then in a very elaborate analysis of each symptom, of the pyrexia and its variations, and of complications. Many illustrative cases are given, and the amount of information sifted and analysed is very great. Chapters on its mortality, on the anatomical lesions, on diagnosis, prognosis, and treatment, follow; but it is not possible within our present limits to analyse these here, and we prefer to pass to the section entitled the Pathology of Spirillum Fever, as it contains those facts which, where all is interesting, are perhaps of most interest.

The examination of the blood is fully detailed, and its characters during the non-febrile and febrile stages are described. In the incubation period, as observed chiefly in inoculation experiments on monkeys, the main difference from normal blood consisted in the presence of granular protoplasmic masses, and by the third day a few spirilla; and during the apyretic intervals in man protoplasmic granules preceded the first appearance of the parasite as the pyrexial stage was reached. In the febrile stages, during the first attack, the spirilla increased in number until the height of the pyrexia, when they rapidly disappeared, being replaced by granular masses and an increased number of leucocytes. In the first relapse the spirillum reappears and remains longer than in the primary attack; in the second relapse it is less abundant, and in cases of third and fourth relapses the spirillum is often not seen, but only some immature filaments. By means of charts the author represents graphically the fact of the increase in number of the spirilla concurrently with the rise of the pyrexia in two typical cases of the first relapse, and gives the following data as pointing to a "real connexion of spirillar blood contamination with the pyrexial attacks of relapsing fever:—(1) Infection is always followed by fever. (2) With the advent and progress of pyrexia the blood-parasites increase. (3) They disappear with the cessation of fever. (4) By contact with the sick and by inoculation of blood containing the spiral organisms or their germs, the disease may be conveyed to new or old subjects." And he adds as "modifying the connexion above implied—(1) The presence of the blood-parasite during several hours, or for one or two days, prior to fever. (2) The sudden onset of pyrexia is not preceded by or attended with a proportionate visible augmentation of the spirillum. (3) The absence of any fixed relation between variation in form and intensity of fever, and varying numbers of the organism. (4) The persistence of the parasite during pseudo-crises and defervescence by lysis" (p. 361). In the next chapter, dealing with etiology, we find much valuable information upon the propagation of the fever by contagion and by direct inoculation (as in the making of post-mortem examinations of infected subjects), with the important conclusions that the disease spreads solely through means of actual contact with the sick, and that no immunity is conferred by a first attack. The author indicates the cutaneous transpiration and the breath of the sick as the probable channels of contagion. The concluding chapter upon the nature of the disease is a review of its main features in the

light of the doctrine of spirillar infection. "Regular relapsing fever was never seen without spirillar infection, and though the infection may fall short of producing such clearly recurrent fever, yet it always tends to induce it. The question whether or not the spirillum alone and *per se* produces the fever cannot be answered until the organism be completely isolated and its pathogenic power tested then as well as after cultivation in other media than the blood. At present no pathologist has succeeded in doing this; but in some comparative instances (e.g., the organisms of anthrax and some kinds of septicæmia), such testing has been accomplished, with the result of demonstrating these parasitic growths to be the *veræ causæ* of disease."

In an appendix Dr. Carter gives an account of his experimental inoculation of spirillum fever in the monkey, some culture experiments, and concurrent fevers at Bombay, chiefly remittent and typhoid. A large number of temperature-charts are given illustrative of the different modifications of the disease.

Although we have but cursorily glanced through this work, it is not because we deem it other than one of the most original and valuable contributions to medicine that has appeared of late years. The pages are full of facts personally observed by the author, and the conclusions he derives from these are drawn up with the caution and pains so characteristic of all his work. The appearance of such a monograph as this adds to the obligations which medical science already owes to the earnest band of inquirers who have done so much to advance our knowledge of fevers in India, whilst it will also do much to stimulate research into the intimate pathology of the fever of which it treats, and of allied specific diseases.

#### OUR LIBRARY TABLE.

*The Surgical Treatment of Hæmorrhoids.* By WALTER WHITEHEAD, F.R.C.S.E., Surgeon to the Manchester Royal Infirmary. London: J. & A. Churchill. 1882.—Mr. Walter Whitehead has published, in a separate form, his paper on the Surgical Treatment of Hæmorrhoids. His mode of operating is, after clearing out the bowels thoroughly by repeated enemata, and with the patient fully anesthetised, to begin the operation by paralysing the sphincter ani by stretching and massage; each pile to be removed is then seized with a forceps, and the mucous membrane dissected from its pedicle; the pile is then left attached to the rectum by its bloodvessels and submucous tissue only; this pedicle is then twisted through, the torsion being relied upon to close the vessels. The little flap of mucous membrane that is left is then stitched with fine catgut to the verge of the anus. It is urged in favour of this operation that it is precise, removing the whole pile and nothing more, that no open wound is left, and that it is easy and quite safe.

*First Aid to the Injured: Five Ambulance Lectures.* By Dr. FRIEDRICH ESMARCH, Professor of Surgery at the University of Kiel. Translated from the German by H. R. H. Princess Christian. London: Smith, Elder, and Co. 1882.—This is a far more attractive-looking little manual than that published by the Order of St. John of Jerusalem. It is printed on good paper, nicely bound, and the few illustrations are well executed. But it does not contain so much nor such exact information as its little black rival. The part that strikes us as being best done is the last lecture on transport, in which the instructions are plain and simple. In some other places too much space is devoted to a description of what the surgeon will do, and what therefore the reader is not to do, and is quite out of place. Many details which are necessary are entirely omitted: for example, in speaking of the temporary treatment of a fracture, the materials out of which splints and bandages to

fasten them on are enumerated, but there is no hint of how long or how wide the splints should be, nor as to where they should be fastened. For burns a mixture of carbolic acid and oil is one of the dressings recommended, but we do not read that it is desirable to add any particular proportion of acid to the oil. But these criticisms merely indicate how difficult it is for even a very eminent surgeon and experienced lecturer to impart the desired amount of knowledge in five ambulance lectures. Her Royal Highness has, however, furnished the numerous pupils of these ambulance lectures with a very pleasant, readable manual which contains a great deal of useful information imparted clearly and well.

*A Manual of Instructions for Stretcher Bearers.* By Dr. G. A. RÜHLEMANN, Surgeon-Major, Saxon Army Medical Corps. Leipzig: Alfred Lorenty. 1882.—This is a small album of twenty-five plates, originally prepared for the Imperial German Army, but now published in several languages. The first plate gives a view of the skeleton, the position of the main arteries and most important viscera, which is by no means accurate; thus the bifurcation of the aorta is placed opposite the second instead of the fourth lumbar vertebra; the femoral artery at the groin is shown close to the outer side of the pubic spine; and the brachial artery is shown dividing into the radial and ulnar above, instead of below the elbow joint. The following plates show simple and ready means of applying pressure to control hæmorrhage; the various modes of applying the triangular bandage, and temporary splints of all kinds; the different plans of lifting and carrying wounded persons; the ways of extemporising stretchers and ambulances, and the Silvester method of performing artificial respiration. The text does not give any directions, so that the album is only of service in refreshing the memory of those who have been previously practically instructed, but for this purpose it is well adapted, as the drawings, with the single exception we have already pointed out, are admirably done.

*Fraser's Magazine.*—The admirers of this serial, and they are not a few, will see, perhaps with surprise, certainly with regret, the announcement in the current number of its discontinuance after the present month. Established more than fifty years ago, its history has been an honourable one; it has occupied a place in the foremost rank of the "monthlies," and the non-appearance of the familiar neat green wrapper at the beginning of each month will be felt by many as the loss of an old friend. Messrs. Longman, however, in the same "breath" as that which proclaims the death of "Fraser," announce the birth of a new magazine, with their own name for its title.

*Christmas and New Year Cards.*—We have received from Messrs. Hildeheimer and Faulkner, of 41, Jewin-street, E.C., some very beautiful specimens of Christmas and New Year cards. Several of these cards are excellent works of art. Most of the designs were exhibited at the publishers' competitive exhibition, held at the Suffolk-street Galleries in August last, when the sum of £5000 was awarded in prizes, the judges being J. E. Mullais, Esq., R.A.; Marcus Stone, Esq., A.R.A.; and G. A. Storey, Esq., A.R.A. The same enterprising firm intend, we understand, to offer the sum of £1000 in prizes for the best eighty albums containing Christmas and New Year cards published by them, and a further sum of £100 for the most dainty fancy articles made or ornamented with their satin pictures.

MESSRS. LETIS, SON, & Co. have published a useful *Map Catalogue*, to which is added a list of atlases, globes, and geographical appendices, British and foreign. The pamphlet will be welcome, amongst others, to persons engaged in educational work.

A GRAND county musical festival is to be held on the 24th inst. in aid of the hospitals of West Cornwall.

# THE LANCET.

LONDON: SATURDAY, OCTOBER 21, 1882.

THE Report of the Commissioners appointed to inquire respecting Small-pox and Fever Hospitals has just been issued. It covers some 500 pages, and deals with so many incidental subjects, that we are unable to do more than give, on the present occasion, a brief account of the principal conclusions arrived at. The main points which the Commissioners have had to decide upon have been the questions: (1) Whether any of the large hospitals belonging to the Metropolitan Asylums Board have or have not injuriously affected the neighbourhoods in which such hospitals have been situated?—and (2) whether, as regards the metropolis, the present arrangements for isolation are desirable and adequate, and, if not, what other arrangements should be made so as to secure to the utmost both the welfare of the patients and the protection of the public against contagion? Amongst the witnesses called with reference to these points were Dr. BUCHANAN, Dr. THORNE THORNE, and Mr. W. H. POWER, representing the Medical Department, and Dr. BRIDGES, representing the Poor-law Department, of the Local Government Board; Sir WILLIAM JENNER, Sir RISDON BENNETT, Dr. BURDON SANDERSON, and Dr. BROADBENT; a large number of the leading medical officers of health of the metropolis; members and medical advisers of the Asylums Board; Mr. ALFRED GODRICHS, who has long been a strong opponent of the existing hospitals; and Mr. PEARSON HILL. With regard to the influence for evil of infectious hospitals upon their immediate neighbourhoods, the question of small-pox is dealt with apart from the other infectious fevers, and it is Mr. POWER's report which has in this connexion received most attention. The Commissioners testify to the ability with which that report was prepared, also to its searching character; and as regards his facts, they freely adopt them,—these facts showing, as it will be remembered, that (to use the Commissioners' words) the Fulham Hospital "is, in some way or other, a centre of infection." Mr. POWER went further; he believed that the influence for harm was exerted by the hospital *per se*, and not to any marked extent as the result of faulty administration, ambulances, &c. And the Commissioners appear to support this view as regards several essential points, for they admit the accuracy of the evidence which showed that personal communication could not account for a large number of the attacks near Fulham Hospital, and that the houses on the lines of human intercourse have not suffered more than other parts of the same neighbourhood. It is true that in attempting to decide whether the spread which took place around the Fulham Hospital was due to a graduated intensity of infection brought about by atmospheric dissemination, or as the result of human movements from the hospital as a centre to the periphery of the affected district, they incline to the view that the spread which did occur may be equally accounted for by both views. We must admit that at first

sight, and in the absence of reading the evidence on which this opinion is based, we hardly see how this can account for the spread being in no way limited to the lines of human intercourse and the roads by which these lines are traversed. But the Commissioners, in dealing with the subject in their recommendations, practically accept Mr. POWER's view as to the dissemination being due to causes not to be remedied as the result of administrative arrangements, by suggesting that inside London the number of small-pox beds at each centre for isolation shall not exceed some thirty or forty. This conclusion must have a most important effect on our future isolation arrangements; it will limit the aggregation of acute cases, from which the harm is alleged to arise, to such an extent as to do away with all possible evil; and it will need some such arrangement as country hospitals for the convalescents and river hospitals for others, such as are also recommended. The other main point is met by a proposal that in the metropolitan districts the isolation of infectious diseases should be dealt with by one single body, that the question should be entirely disconnected from Poor-law administration, and that London should be divided into hospital districts, each having a definite amount of isolation accommodation for the several infectious fevers. To these and other points we shall recur. In the meantime we would say that the Report appears to be one of the most valuable contributions to the question of the health of the metropolis which has ever been issued.

AMONG the many occurrences connected with the recent campaign in Egypt is one to which we refer with reluctance and regret—we mean the pertinacity with which certain special correspondents of the newspapers have attacked the medical officers of the army, and have attempted, by unscrupulous statements and unfounded charges, to show that the department has broken down, and that the provision made for the sick and wounded was wholly inadequate. We have ever been uncompromising advocates for the liberty of the Press, but that very liberty carries with it a serious responsibility—that of taking every precaution to test the truth of statements affecting the character of individuals and the conduct of the various departments of the public service. In this respect we regret to say there has been a grievous shortcoming on the part of some of the staff of correspondents. In the very beginning of the war it was alleged by one of them that the household cavalry had been embarked "without the smallest supply of drugs, plasters, or other medical paraphernalia," while a very moderate amount of inquiry would have shown that the statement was quite unfounded. Again, a very serious charge was brought against the Department of having no chloroform with the troops in the field, and it was stated that "at Ismailia, at the base, a Life-guardsman's arm had to be removed at the shoulder without chloroform, because there was none forthcoming." It appears now, on unquestionable evidence, that there was abundance of chloroform not only for our own wounded, but for a large number of the enemy who were brought into our hospitals; and that the Life-guardsman referred to was operated upon under the influence of chloroform is vouched for by a gentleman who was present at the operation. That some delay occurred in fitting out the base hospitals at Ismailia is undoubtedly

true, but this was in no respect the result of a break-down of the Medical Department, but arose from the rapidity of Sir GARNET WOLSELEY'S advance, and the inability of the Transport Department to keep pace with it. When the transport difficulties were so great that the troops were obliged to be put on half rations, it would have been surprising indeed had there been an unlimited supply of everything required for the medical branch of the service. A comparison has been drawn in a letter in *The Times* between the hospitals of the English and Indian troops, very much in favour of the latter. But this is easily explained by the fact that while the troops moving to the front from Alexandria were, from unforeseen events, far in advance of their supplies, and furnished with inadequate means of transport, the Indian troops landed with a complete transport service, and were able to move forward with it, instead of being compelled to do so in advance of it. The condition of the hospitals of these two forces respectively depended upon this circumstance, and not, as alleged by the writer in *The Times*, on the difference between the station hospital and the regimental systems. He does not appear to be aware that the Indian hospital service was reorganised by the present Director-General, when Principal Medical Officer in India, on the principles of the station hospital system, and that its success in Egypt, as described by him, is a strong testimony in favour of the present organisation. In fact the system is now identical in the two services. The latest denunciation of the Medical Department appears in the form of a complaint as to the dirty state of the decks of the troopships which have brought home the sick and wounded, as compared with those employed on their ordinary service. We have seen letters from competent and impartial persons disputing the accuracy of the statement; but if there were a difference it could easily be accounted for by the importance of disturbing the sick and wounded as little as possible, and the necessary abstention from wetting the decks around and under the cots of the wounded men.

In most of these charges against the Medical Department there has been such an evident bias and such a hostile feeling displayed, that we are strongly disposed to believe they have been brought forward mainly with a view to discredit the present organisation of the Department, and enforce, if possible, a return to the old regimental system. Have the writers forgotten, or have they ever studied, the frightful break-down of the latter in the Crimea? Have they forgotten the successful working of the present system in the Afghan and South African wars? or do they purposely ignore the testimony borne to it by the Field Marshal Commanding in Chief, when he said, in reference to the latter, that "he had been unable to put his finger on any defect in the organisation and working of the Department"? So far as any shortcoming has been shown to have occurred in the Egyptian campaign, it has been connected with defective transport. What would have been the case had the regimental system been in force, which requires more than double the amount of transport? But there is another very serious question left out of view. Had we been still under the regimental system, commanding officers would most undoubtedly, as of old, have laid their hands on every effective soldier employed in the hospital and sent

him into the ranks, and the sick and wounded would have been relegated, as in the Crimea, to the care of untrained regimental orderlies, consisting of the weak, inefficient, and useless men of the corps. Again, it has been generally admitted by officers who have seen field service that never were the wounded more quickly, more carefully, and with less suffering, removed from the field than they were by the bearer companies of the Army Hospital Corps. How would this duty have been done if left to the musicians and drummers, or to such native help as could have been picked up in Egypt? These are questions deserving careful consideration, and we believe they will receive it from the Secretary of State for War.

It has been stated that the Principal Medical Officer of the force has applied to Sir GARNET WOLSELEY to order a court of inquiry into the charges which have been so unscrupulously preferred against the Medical Service, and that the Director-General has been carefully investigating the facts connected with the treatment of the sick and wounded. We trust that Mr. CHILDERS will take means to make public the result of such inquiries, and that he will appoint a committee to examine into the whole matter, and thus give an opportunity to the detractors of the Department to bring forward specific instances of neglect or mismanagement, instead of dealing in generalities which, we believe, may be truly described as fictitious and groundless.

FIFTEEN years have passed since TRAUBE lamented that we have no definite experimental knowledge of the character of the intestinal movements in diarrhoea, and the series of experiments by NOTHNAGEL, of which we gave some account last week, constitute the first attempt to supply the information. It is commonly assumed that during diarrhoea the peristaltic movements are increased in energy, and more constant than in normal circumstances. The experiments of NOTHNAGEL were made upon the colon, as well as on the small intestine. The production of a moderate degree of inflammation proved a more difficult task than he had anticipated. The most suitable agent was a concentrated solution of chloride of sodium. Five centimetres of this were injected into the rectum several times in the course of twenty-four hours, the return from the anus being prevented. The movements of the bowel were observed next day in the usual salt bath. NOTHNAGEL, however, never succeeded in exciting inflammation in a larger tract than from thirty to sixty centimetres, and the enteritis was always slight in the upper, and considerable, and often hæmorrhagic, in the lower part. The production of inflammation in the small intestine was much more difficult. Attempts to produce it by injecting irritant substances into the stomach by means of an œsophageal sound, and thus to imitate an occasional cause in man, were unsuccessful. Even sulphate of copper failed. Strong solutions caused rapid death, and weak solutions had no effect. Only local inflammation could be produced by the injection of a concentrated solution of chloride of sodium through the wall of a loop of the small intestine, withdrawn from the abdomen for the purpose through a small incision.

In both large and small intestine the peristaltic movements were rapidly increased by the inflammation, and the affected portion became filled with fluid, manifestly inflam-

matory exudation. The peristaltic contractions took the form partly of oscillatory movements, and partly of circular constrictions. Sometimes, however, the affected portion became the seat of a prolonged tonic contraction, which involved both the transverse and longitudinal muscular fibres. Very different, however, was the condition when twenty-four or forty-eight hours were allowed to elapse after the injection. The inflamed and empty section of the bowel was motionless, no contraction could be seen in it as long as the experiment lasted, and this even when the inflammation which had been excited was slight in degree. The conclusion therefore is that the early stage of inflammation is attended with very strong contractions in the inflamed portion, but that when the initial period is over and the inflamed part of the bowel is empty, the movement is not greater than in the normal bowel. Moreover, it appears that the contents of the bowel are, in the early stage, moved through the inflamed portion with increased rapidity.

In the course of his experiments NOTHNAGEL had many opportunities of observing the occurrence of intussusception, which frequently resulted from a vigorous peristalsis in the uninjured intestine. The invagination always occurred from above downwards, a strongly contracted portion passing into a part in which the contraction was slighter, or which was at rest. The length of the intussusception was always slight—from half a centimetre to two centimetres. It usually quickly ceased, in consequence of the cessation of the contraction; and only once did it last as long as ten minutes. It is a frequent occurrence in the small intestine, but is comparatively rare in the colon. On one occasion an invagination of the colon was distinctly removed by the antiperistaltic contractions which were set up by an injection of chloride of sodium into the rectum.

Another subject investigated by NOTHNAGEL is the influence of morphia on the intestinal movements. It will be remembered that he discovered in his earliest experiments that a sodic salt placed in contact with the outer surface of the intestine of a rabbit causes a local contraction which passes upwards. This effect was found to be prevented by a preceding subcutaneous injection of a small quantity of morphia, one to four centigrammes. Even bicarbonate of soda, which under normal circumstances causes a very energetic contraction, no longer produces the effect. NOTHNAGEL ascribes the effect to the stimulation of a nervous mechanism antagonistic to that which is excited by the sodic salt. If, however, a much larger quantity of morphia was injected—ten centigrammes, for instance,—not only does the sodic salt produce its customary effect, but the constriction is much more energetic than under ordinary circumstances. This anomalous effect seems to indicate that, while small doses of morphia stimulate, larger doses paralyse the inhibitory nervous mechanism. Morphia appears thus to exert on the intestinal apparatus an action comparable to that which digitalis exercises on the innervation of the heart, which consists in a stimulation or paralysis of the inhibitory fibres of the vagus, according to the dose employed. Other experiments seem to show that the action of morphia on the intestine is exerted through the splanchnic nerves. The constipation produced by morphia is assumed to be the result of a stimulation of the inhibitory fibres contained in the nervous trunk, aided by a diminution in the intestinal secretion.

It is surprisingly difficult to make anybody recognise the money value of medical services, but those who are officially responsible for the administration of the Poor Laws would seem to be specially oblivious to this view of the facts. There is a wide-spread and very deep persuasion on the part of the public that we of the medical profession are so enamoured of our work that we are always eager to practise whenever and wherever a patient can be found, wholly regardless of trouble or recompense. This is doubtless an exceedingly flattering compliment to pay to our professional zeal, but does it not a little reflect on our character for common-sense intelligence as men of the world? Those who thus praise our devotion to science do so at the cost of a considerable sacrifice of the respect in which they hold our intelligence as men of business. It is only the "doctor" who is expected, and confidently counted upon, to labour without reward. The ingenious philanthropist, rich in the wit of being liberal with other men's stock-in-trade, has never hit on the device of instituting a charity for the furnishing of legal advice and assistance to neccessitous debtors, or poor folk troubled with heavily mortgaged estates or interminable law-suits; and though it is true that religious enthusiasts do establish costly missions abroad and spiritual enterprises at home, they are always careful to make special provision for the payment of their clergy. Who ever heard of any benevolent undertaking for the benefit of sick or sound, friend or foe, fellow-subject or alien, which was based, as its fundamental proposition and start-point, on the assumption that the services of its principal and active agents were to be had for nothing—except the gratuitous toil and time to be contributed by the medical profession?

At Birmingham, where they have the caucus and other refinements of an advanced civilisation, the guardians of the rates—we must decline to style them guardians of the poor—have, it seems, conceived the brilliant project of economising by appointing for the present *quasi*, and in the future they hope wholly, honorary physicians and surgeons to the care of the sick in their workhouse. They think, forsooth, the field for pathological research afforded by the local poor-law infirmary so good that "first-rate" men, being members of our most enthusiastic and self-sacrificing profession, will naturally rush to occupy it. We fear the calculation is a sound one in an economic sense, though flagrantly immoral in the light of public prudence and equity. Mr. CHESHIRE writes to the *Birmingham Daily Mail* to protest, and points out that the local profession contributes services to the money value of £80,000—on the Poor-law scale of minimum remuneration—to the aid of the sick of Birmingham. There is not the smallest reason to suppose that this argument, though conclusive in itself, will influence the guardians of the rates. It is their commission to reduce the charges on the public pocket to the lowest practicable figure, and, if they can see their way to getting the bulk of the work done for nothing, or next to nothing, it is difficult to hold them to blame for doing so.

In short, the reform that every sensible ratepayer must desire—because it is not just or expedient that the breadwinner should labour for nought—is one which can only be accomplished by the medical profession itself. We do not say that medical men ought to resort to the vulgar artifice of a

"strike," but we certainly think the time has arrived when this question of equitable remuneration for the services they render to the sick poor, particularly those of the pauper class—because their poverty is recognised by the State—should be thoroughly investigated, and, with due deliberation of course, and full notice, an ultimatum submitted to the Local Government Board and the Legislature. The determination to force work, for which payment is refused, on the medical profession, is daily gaining strength, and showing itself throughout the country. In London, guardians of the rates are resorting to the practice of sending paupers, or allowing them to go, to public hospitals when an operation is necessary, and then refusing to recompense these charities. The proceeding is a pitiful artifice to save a fee, but it must be confessed our interest in this matter is only secondary, because a fall out about funds between the committee of a hospital charity carried on by medical men gratuitously—for the glory of a posse of gentlemen who do not contribute one five-hundredth part as much as the medical staff contributes but appropriate all the *kudos* for philanthropy—and a board of guardians is not a squabble in the course of which honest men are likely to come by their own. It is opposed to all principle to sponge on the public hospitals for medical relief for the State poor, but neither the physicians and surgeons of hospitals, nor the under-paid medical officers of Poor-law districts and workhouses, will gain much by the adjustment of this difficulty. It is with the broad question of fair pay for loyal and laborious labour we are concerned. We say the medical profession must answer that question for itself. How precisely it should proceed we are not at present prepared to point out.

There would be no great difficulty in proposing a solution of the problem, but it cannot be solved unless, or until, the whole profession is agreed on the preliminary proposition that medical services ought to be required, and is resolved to refuse to work without pay. In the present state of opinion amongst us, there can be no doubt that if the Local Government Board were to yield to the parsimony of guardians, and agree to abolish paid offices for medical men altogether, in less than a week the sick would be attended gratuitously by an army of volunteers. Neither lawyers nor divines would give their services gratuitously in such an emergency, but medical men would. Some would be impelled by professional enterprise chiefly, while others would be moved by feelings of humanity, so that practically the sick poor would suffer comparatively little, if anything, by the desertion of their official friends and protectors. How is it possible, in the face of this fact, to compel the guardians of the rates, or the Local Government Board, to deal equitably by its medical officers? Manifestly the hope of coercing these authorities is vain, because the only argument by which they could be reduced to reason is inadmissible. It remains to regret the absence of a sufficient spirit of co-operation in the profession to enable us to act together for the common good. We may be proud of our high-souled philanthropy, but we cannot congratulate our profession on its *esprit de corps*, or collective intelligence. It is useless protesting year after year against the parsimony of Poor Law authorities, because they know perfectly well, and we know, that medical aid is

always to be had for the asking, and seeing that our services are always forthcoming, and the best are the most freely offered, medical labour is not unnaturally held to be cheap.

THE provincial medical schools, like the majority of metropolitan ones, continue to believe in beginning the winter's work with an Introductory Address. We were able to report pretty fully last week the address at Newcastle by Dr. THOMAS OLIVER; at Queen's College, Birmingham, by Dr. RICKARDS; and that at Leeds by Mr. JAMES WALKER; all of which will well repay perusal. These addresses are interesting not only as statements of the ordinary facts and considerations which it is thought wise to present to students of medicine at the beginning of the session or of medical study, but as indications of provincial feeling as to the state of education generally and medical education in particular, and of the efficiency of provincial as compared with metropolitan medical teaching. The existence of such institutions as the Victoria University at Manchester, the University College at Liverpool, the Physical Science College at Newcastle, Mason's College at Birmingham, and others, undoubtedly gives to provincial medical schools a new advantage in their competition with their rivals in London or Edinburgh. It is well that it should be so. We should be sorry to see an indefinite multiplication of universities, or even any serious addition to the existing number. Dr. RICKARDS, in his excellent address at Birmingham, expressed a hope that a University of Birmingham might become something more than a mere dream by the affiliation of the numerous institutions in Birmingham devoted to higher education. He seemed to regard it as a disadvantage, if not a hardship, that a Birmingham student could not get his degree of Doctor of Medicine at home without going elsewhere for it. We cannot go so far or so fast as Dr. RICKARDS. It is curious that, just when our American friends are trying to reduce the number of their degree-granting institutions, and just at the very time when a Royal Commission is reporting in favour of a great reduction in the number of bodies for granting medical licences at home, there should be a tendency to claim a university for every large provincial town. We repeat, we do not go so far as Dr. RICKARDS. Universities should be neither parochial nor provincial institutions, but national ones, so few and so constituted as to give national, as distinguished from local, value to their degrees. But we go a certain way with Dr. RICKARDS. It is a matter of great satisfaction that the centres at which a sound and substantial general education is to be got are multiplying, and are asserting themselves so actively in those towns which have long been associated with provincial medical schools. The competition implied in such a state of matters can do nothing but good. Our own metropolitan schools will be stimulated most beneficially by it. The time has gone by when London, Edinburgh, or Dublin can rely too confidently on superior teaching facilities, and every year tends to make the provincial competition more keen. So long as this does not take the shape of a multiplication of degree-factories, it is almost an unmixed advantage. There will soon be no longer any local monopoly of learning, or of science, or of professional skill. One of the advantages of this competition of the provinces may be to induce some concentration and combination of metropolitan schools.

Birmingham has set a good example in this respect. Its medical school began in 1828 as the Birmingham Royal School of Medicine and Surgery. Local medical energy led to the formation of a second school in 1851—Sydenham College. The two institutions in 1858 were wisely merged into one—Queen's College; and in 1873, for the purposes of clinical teaching, the practices of the General and the Queen's Hospital were amalgamated, and students were required to attend each hospital alternately for six months. A similar consolidation has taken place in Newcastle-upon-Tyne, very much to the strengthening of the school.

The time may come when a reduction in the number of licensing bodies will set the Medical Council at liberty to ascertain the efficiency of the medical schools and the supply of means of teaching and of capable teachers; meantime, the competition of schools is the only fact to rely on for ensuring better medical education.

## Annotations.

"Ne quid nimis."

### SURGICAL OPERATIONS AMONG THE WOUNDED AT NETLEY.

THREE important surgical operations have been performed among the wounded men who have arrived at Netley from Egypt—viz., amputation of the thigh, excision of the hip-joint, and excision of the shoulder-joint. In the case of thigh amputation, the patient was reduced to the lowest ebb by the effects of his wound—a shattered knee-joint with diffused suppuration involving the whole thigh and upper part of the leg—and by diarrhoea, which it was stated, had been continuous for a fortnight previous to his admission. Removal of the damaged limb was considered to afford the only chance of saving life, and it was performed at the lower third of the thigh. The patient survived the operation several days, at first exhibiting marked signs of improvement in general condition, but ultimately sank exhausted. In the case in which excision of the head of the femur was performed, a bullet had entered near the great trochanter on the right side, and the joint was found to have been opened. Suppuration was in this case extensively diffused among the muscles of the corresponding nates and upper part of the thigh. On the removal of the head of the femur, which was entirely denuded of cartilage, it was discovered that the bullet had traversed the acetabulum, fissuring the bone in its neighbourhood, and had passed beyond reach of detection. The ultimate chance of recovery, with the complication of a fracture of the pelvis, is of course very small; but so far the condition of the patient, as regards freedom from pain, temperature, and general constitutional symptoms, is considerably better than it was prior to the operation. The portion removed in the operation included the head, neck, and great trochanter; the connexion of the lesser trochanter, which had escaped injury, with the shaft of the femur, was left untouched. The patient in whom excision of the head of the humerus was performed is going on as well as possible, and will no doubt make an excellent recovery. The injury in this case was also caused by a bullet. The missile had entered the shoulder on its outer aspect, had traversed the joint, farrowing the head of the bone deeply in its passage, and had escaped just above the axilla. All the operations were skilfully performed by Surgeon-Major Tobin, Assistant Professor of Military Surgery, who is in charge of the surgical division of the hospital in which the wounded are placed for treatment. Like all surgical opera-

tions performed at Netley for several years past, these were done with strict antiseptic precautions; but the difference of the conditions under which antiseptic treatment is followed in cases where suppuration has been going on for weeks and in others where it is adopted as a primary process need hardly be adverted to. As yet no death has occurred among the wounded who have been received at Netley from Egypt but the one above mentioned, which occurred after amputation of the thigh, and in that instance the case was all but hopeless from the first. Minor operations, such as removal of sequestra, extraction of bullets, &c., have been performed in numerous instances.

### OFFICIAL REPORT ON THE BANGOR EPIDEMIC.

THE epidemic of enteric fever which has been prevailing in Bangor since June last is one of the most extensive outbreaks which has occurred in this country within recent years. According to Dr. Barry's official report to the Local Government Board, the number of persons attacked in Bangor and its neighbourhood from the commencement of the epidemic to Sept. 12th last was 548, and this number has unfortunately been increased since that date. The town of Bangor has a population of 8240. Near to it lies the Local Board district of Bethesda, with a population of nearly 7000; and other places affected by the epidemic are included within the Bangor rural sanitary district. The principal water-supply for all these localities is the Bangor public service, which is derived from a stream called Afon Gaseg just below its junction with the Afon Llaver, the supply being conveyed in a nine-inch main to a filter-bed of sand and gravel, and thence to a small reservoir. The Bangor district is throughout provided with sewers, but the ventilation is described in the report as being extremely defective; the house-drains are of faulty construction, the various waste-pipes being so contrived as to facilitate the entrance of foul air into the dwellings. The principal portion of the epidemic may be divided into three periods. The first, which was characterised by a series of "dropping cases," commenced in the last week in May, and continued till the first week in July. The second was marked by the occurrence of a sudden outbreak simultaneously affecting the town and its neighbourhood, and extending over the second and third weeks in July. Then came a third period, characterised again by a long series of dropping cases. At the commencement of the epidemic suspicion attached to the water-supply as the cause of the disease, and it was ascertained that the persons attacked had nothing in common as regards sewerage, milk supply, or other ordinary sources of infection. Out of some 3724 houses in the affected districts 2024 received their water from the Bangor Water Works and 1700 from other sources, and after the epidemic had continued some five or six weeks—namely, up to July 7th—Dr. Barry found that all the cases, with the exception of one group at Llwynrhindir, had one and the same water-supply—namely, that from the Bangor Water-works. What, then, was the condition of this water-service? Dr. Barry reports that in the neighbourhood of the in-take above Bethesda, a number of sources of pollution were found, including the drainage from privies, pig-styes, and a cow-house, in addition to the drainage from two houses at Llwynrhindir, which, as shown in a plan, was conveyed direct into the stream above the point of in-take. Now these houses were those which formed the exception above referred to as not receiving the Bangor water; in one of them well-marked enteric fever had occurred towards the end of May; and experiment proved clearly that the infected drainage could easily have passed into the company's filtering reservoir. Here, then, we have established a direct means of communication between the consumers of the

water, and the specifically poisoned contents of a drain at Llwynrhaidir; we have also cases of enteric fever occurring simultaneously at a distance of some miles apart, and an absence of any other common cause than that of the suspected water-service. The second outburst was probably brought about by somewhat different circumstances. Owing to an accident it appears that the water was delivered to the town on June 30th and July 1st without passing through the filtering-beds, and under circumstances which easily admitted of any accumulated filth on the surface of the filtering material being washed direct into the mains. The deposit on the filtering material can hardly fail to have contained some of the specifically poisoned drain filth from Llwynrhaidir; besides which, though the works belong to the sanitary authority, the sand had not been removed for a long series of years. From ten to fourteen days after this occurrence a large and simultaneous outbreak occurred, affecting, amongst other places, several new localities. The third stage of the epidemic was easily brought about. Such were the conditions of sewerage and house drainage that, as Dr. Barry says, "ample provision existed in Bangor for favouring the spread of such a disease as enteric fever," and we ourselves pointed out some time since that in view of the great want of proper sewer ventilation, together with the direct connexions existing between those sewers and the interior of dwellings, the worst results might be anticipated unless very active and prompt measures were at once adopted. Indeed the conditions were such that a specifically poisoned sewer air was, to all intents and purposes, laid on to many of the houses. The action taken is described by Dr. Barry in a postscript written after a second visit to Bangor on September 12th. At that date the authority were found to be acting energetically in improving the water-service, providing sewer-ventilation, removing nuisances, and securing isolation. But unfortunately the needed action had been delayed, and this whilst the disease was widely spreading. The attention of the sanitary authority was drawn as early as August 3rd to points of such urgent and imperative necessity as the provision of efficient means of sewer ventilation; but it was only ordered to be done, and this to a limited extent, on Aug. 31st. So also the removal of the filtering material, which was presumably specifically contaminated, and hence constituted a principal source of danger, was not executed until Sept. 5th. These delays must be regarded as extremely serious, but now that the needed remedial measures have been adopted it is to be hoped the disease will rapidly disappear. Indeed a marked abatement is already reported to have taken place. We may add that, both as regards the cause and the means of spread of the disease, Dr. Barry expressed his entire concurrence with the views held by Mr. Rees, the medical officer of health.

#### "THE TREATMENT OF PAUPER LUNATICS."

SIR H. W. GORDON, in a letter which we print in another column, urges the institution of a "Receiving house" for lunatics, to which cases could be sent pending the process of placing them under certificates. This proposal is identical with that which was made by THE LANCET Commission on Lunatic Asylums in 1876-77. Dr. Mortimer Granville, in his evidence before the Select Committee of the House of Commons, offered the following suggestions in reply to questions by the Chairman:—

"8876. *You would send the patients to a hospital constructed for the treatment of the insane, I suppose?*—Yes, if necessary. You do not send a case of apoplexy to a hospital in the ordinary way, and cases of delirium tremens are seldom sent to a hospital; puerperal mania would not be sent to a hospital, at any rate in that stage when it is difficult to tell whether it is not puerperal fever with excessive excitement; it would not be sent at once, the case would be treated. If the ordinary medical

attendant conceived it was desirable to remove the patient, he could then be removed, but as to a hospital, without any preliminary formality of certificates. In the event of its turning out to be a case not involving insanity the arrangements could take place in the ordinary way, and the patient would never afterwards be spoken of as a lunatic, or as having been a lunatic.

"8877. *Supposing that the recovery did not take place, then the eventual confinement in an asylum must be under regular official safeguards, I suppose?*—Certainly. The certificate to be given by the official in the name of the Lunacy Commissioners would be given within twenty-four hours or so after the admission of the patient to the asylum.

"8878. *And it would state either this is a curable case, and had better be treated as a curable case; and the patient may be out in a certain number of days or weeks, or it is probably a chronic case; that could be stated in the certificate?*—Yes, and the case treated accordingly. My proposal would be that attached to each public asylum there should be certain probationary wards set apart for the reception of cases of a doubtful character; that no patient should be removed to the other portion of the asylum or detained as a lunatic until after the reception of an official certificate by a medical man acting in the name of the Commissioners in Lunacy, and never likely, or qualified, to be called as a witness in a court of justice, or in fact engaged in private practice in any way."

This is the proposal we have supported, and which we believe would effect a solution of the difficulty of dealing with doubtful cases. We have also shown how by making special institutions "hospitals" in the true sense of the term, a vast saving would be effected for the ratepayers. In 1877 Dr. Mortimer Granville wrote as follows:—"In Middlesex the admissions to the asylums at Hanwell and Colney Heath during the year 1875 amounted to 1054. The discharges and deaths were 1044. Probably about 30 per cent. of these case-endings occurred within six months of admission. The average number resident in the county asylums is now 3900. [This was before Banstead was opened.] The accommodation required, for new cases only, would not exceed 1000 beds for the entire county. In Surrey the total of admissions in the same year at the two asylums, Wandsworth and Brookwood, (before the enlargement) numbered 834. The discharges were 568, of which something like 30 per cent. would take place within six months. There was an average number resident of 1699 in the asylums. A hospital with 600 beds would probably meet the utmost demands of the county for recent cases, and the strict purpose of cure. Something should be added to the above calculations for the pauper cases sent direct to the licensed houses; but it is difficult to determine the precise allowance to make. The general argument is not, however, affected. One curative establishment—or, still better, two—in Middlesex, and one in Surrey, not exceeding the manageable proportion of 600 beds, with an ample medical staff and a large proportion of attendants, would do more to keep down the burden of insanity by curing the highest proportion of curable cases, than the most energetic and skilful use of the machinery at present employed." We are glad to find that Sir H. W. Gordon substantially endorses the suggestion.

#### "NERVOUS SPORTSMEN."

A CONTEMPORARY observes:—"There are many sportsmen who, do what they will, are unable to avoid a painful trepidation, palpitation, or state of nervousness when walking up to the dog at its point; and the same if a bird or covey rises suddenly without being pointed by the dog." Such "nervousness" ought rather to be designated excitability. It is nearly always constitutional, and therefore incurable. In short, it is not a disease or morbid condition, but a state of impressibility. Of course the condition may be temporary and connected with, or consequent upon, some exceptional deficiency or impairment of the power of control. Steadiness as regards the nervous system is very

much a question of reserve or accumulated force. The strong are "composed" because they have within them that consciousness of force which gives buoyancy and self-possession in action. In some cases the so-called "nervousness" of the enthusiastic sportsman is a direct consequence of his enthusiasm. He is eager to a fault, and so anxious withal, that in the endeavour to acquit himself creditably in the field he is unable to make even a respectable appearance. The heart beats, the eyes dance, the hand trembles, or even visibly "shakes," and of course good shooting is out of the question. This is why many a man who is a fair shot when alone or with one keeper, is unable to hit a haystack—as the saying goes—when criticising eyes are upon him. It is so in everything and all the world over. Practice may in certain cases reduce the magnitude of the trouble, but "nervousness" is constitutional with many a too "enthusiastic sportsman," and he will be increasingly "nervous" as his enthusiasm augments.

### SPACE ABOUT HOUSES.

SPECIAL inquiry has been made, for the purposes of the Local Government Board, into the circumstances which have caused an exceptionally high death-rate in Ashton-under-Lyne, and the inquiry has been conducted by Dr. Ballard. During the past eleven years the death-rate of the borough has varied from 23 to 31 per 1000; there has been such heavy infantile mortality, that only about four-fifths of the infants born have completed one year of life, and only about two-thirds of them five years of life. Diarrhoea has been exceptionally fatal, and the large general mortality has been to a great extent the result of those zymotic diseases which are known to flourish and commit the greatest ravages in places where filth abounds. There are obviously many conditions in Ashton which have contributed to this serious result, but one above all others is striking, and it is the more worthy of note because when once it has been allowed to come into operation it is all but impossible to get rid of it, except at a cost which must often be regarded as prohibitory. We refer to the overcrowding of houses on space. Dr. Ballard illustrates his report by two lithographs, showing certain districts where disease has been especially rife. They disclose the existence of long narrow blocks of houses with hardly any space between them, and having their ends for the most part shut in by other houses in cross streets. The interior of each of these blocks is thus constituted a long narrow well, in which the air is necessarily almost stagnant. Unfortunately, too, the building by-laws for the borough, instead of attempting by degrees to remedy this state of things, tend to perpetuate it, for instead of insisting that there shall be a reasonable area of open space behind every dwelling-house, they sanction a space too small in itself, and this may be situated either at the side or at the rear. Houses can thus at the rear be brought into close contact; and not only so, but in the very houses most needing a circulation of air about them—namely, in the dwellings of the poor—the permitted minimum of space may be encroached upon by the erection of a privy and an ash-pit. This, under any circumstances, would be serious enough, but when we read Dr. Ballard's description of these receptacles, all wonder at a large zymotic and infantile mortality disappears. Filth reigns supreme in the allotted open spaces, and so utterly revolting were the conditions met with that Dr. Ballard, feeling convinced that his description of them would be regarded as exaggerated, took an opportunity of securing the company of the mayor in a visit to some of the localities in question. Thus, not only is the air in the limited space about houses stagnant, but the atmosphere of each elongated well-like space is necessarily impregnated with emanations from the most dangerous kind of filth. Indeed, as Dr. Ballard says, each such

block is nothing short of a night-soil and ashes depot, closely surrounded with human dwellings, into which the most dangerous kind of filth emanations must perforce habitually enter by the door and windows. The removal of filth under such circumstances necessarily increases for the moment the prevailing nuisance, and hence the inhabitants, in order to put off the offensive process as long as possible, store up the largest possible accumulations of refuse, until at last it has all to be carried through their houses into the adjoining street. No more striking instance could be brought forward to show what evils result from faulty building regulations as to space about houses. It is a common thing to find in bye-laws which are not of recent date a discretionary power as to the open space about houses, the builder being allowed to place it either at the side or at the rear, and this even when the minimum space provided is but small. No greater mistake can be made. A definite amount of open space should always be insisted on at the rear of each dwelling, however much additional area may be desired at the side; and the space at the back which should be absolutely free from buildings should, even in the smallest houses, never be less than one hundred and fifty square feet. The evils attendant upon a stagnant atmosphere about houses are not sufficiently recognised, although there is already reason for believing that it is a principal factor in the production of much preventable disease and death; and when to stagnation there is added the further evil of pollution of atmosphere the result is probably especially fatal to the infant population.

### SULPHUR AND MALARIA.

THE influence of sulphur compounds on organic life is familiar. It is seen only too clearly in the aspect of vegetation in many of our manufacturing districts, while the probable dependence of specific diseases on an organised contagium renders the familiar method of disinfection by sulphur another illustration of the fact. Observations on which we have lately commented afford strong reasons for believing that the active agent of malaria also consists of low organisms. It is, therefore, not surprising if sulphur emanations should be found to exert a marked influence on malaria, and some interesting facts have been lately collected by M. D'Abbadie, to show that this is actually the case. In Sicily, deposits of sulphur and intermittent fevers are both common, but occur for the most part at different elevations. In some places the sulphur deposits are found at a low elevation in malarial plains. In these districts the labourers in the sulphur works enjoy an almost complete immunity from intermittent fever, not more than 8 or 9 per cent. suffering, whereas of the inhabitants of neighbouring villages not less than 90 per cent. are attacked. In some travels in Greece, published by M. Fouqué, is an account of the ruins of a large city (Zephyria) situated in a marshy plain, in which it is impossible to pass the night without being attacked by ague. Three hundred years ago, it is said, the city contained forty thousand inhabitants and thirty-eight churches. Paludal fevers gradually destroyed the population. Twenty years ago only two hundred inhabitants remained, languishing and ill. They refused to leave the place, and the last of them died during Fouqué's visit. It is certain that malaria cannot have prevailed to the same extent during the period at which the town was in its rise and full development, and it is also noteworthy that the soil beneath the town contains abundant deposits of sulphur which was formerly worked in the vicinity, and the decadence of Zephyria dates from the discontinuance of these sulphur workings. Moreover, Fouqué has noted another instance of the same relation. The marshy plain of Catania

is traversed by the Simeto, and is infected by fever. On the western border of this plain are some sulphur works, at which are a number of inhabitants who suffer little, although a village not far away is deserted. In Ethiopia certain elephant hunters expose their naked bodies daily to a fumigation of sulphur in the belief that this will preserve them from malaria, and certainly they enjoy an almost complete immunity from the disease, although some of the districts are so unhealthy that not long ago a whole caravan perished.

#### EXPERIENTIA DOCET.

IN the popular mind, and to a less extent in the professional, there is a consensus of opinion regarding the value of experience in the treatment of disease, which, when carried to an extreme point, as it often is, must be misleading and injurious in its effects. The days were, and in some districts and among many people the custom remains, when seniority alone gave position as a consultant, and men's opinions were valued chiefly by their number of grey hairs, and for a certain careful attention to the proprieties manifested during a long course of years. This custom, like many that have stood the test of time, has much of truth to recommend it, as, during a comparatively late period in the history of medicine, knowledge was so empirical and indefinite, the study necessary for degree or licence (even when these were taken) was so slight and superficial, and examinations were such formalities, that only a prolonged acquaintance with disease, gained at the bedside, could give the authority necessary to the consultant. Experience was the chief, if not the sole teacher; and it was years before the young practitioner could obtain sufficient to cope with intricate cases of disease. In these days of accurate observation, of such rapidly advancing knowledge, of delicate instrumental aids to medical inquiry, the well-grounded student commences work with advantages against which simple experience cannot be placed, and the conscientious senior envies him his increased resources. The time is not likely to arrive when the newly fledged and highly trained youth will be equal to all the sudden requirements put upon him, or will feel independent of the more mature, though perhaps empirical, opinion of one having a longer acquaintance with the natural history of disease; but what we would point out is the lessening value now put upon experience, if that, alone or chiefly, is what constitutes the claim to superior wisdom. Fortunately for those needing medical counsel, there are many men of large experience possessed also of all the modern aids in their work; while the class of practitioners is rapidly increasing who carry their studious habits through life, correcting and improving their knowledge by close contact with disease, and ready at all times to give reasons for their faith. Superstition and secrecy in medicine are already almost things of the past, and the sagacious nod is not now thought sufficient evidence of profundity. It is to the men who remain students that we must look for trustworthy opinions and advance in the study of medicine, as without the accurate and painstaking care so necessary to the thorough knowledge of individual cases of disease no amount of so-called experience can form the basis of reliable views. An uneducated nurse of long familiarity with sickness acquires no knowledge whatever as to the real essence of the various diseases, and the effort of all medical legislation, examination, and training is to rid the profession of that class of men who are but superior nurses. It is necessary to warn the junior practitioner to discard, at all hazards, hasty and ill-considered observation, as he but too readily drops into a rule-of-thumb method of work, which is as demoralising to himself as it is detrimental to his patients. Such men may become successful money-makers, but cannot possibly become safe guides in disease; they obtain a large

amount of experience, which is but a snare—a snare unfortunately to the public as well as to themselves. We may at least feel a satisfaction in knowing that this class of men is rapidly diminishing, and, with the present opportunities for training, need no longer exist.

#### SCARLET FEVER IN LONDON.

THERE appears to be no just ground for the reports of alarmists as to exceptional prevalence of scarlet fever in London. There is no disease which has more strongly marked seasonal fatality than this exanthem. The Registrar-General, when specially dealing with seasonal mortality in London in his Annual Summary for 1880, said, with reference to the mortality curve of scarlet fever, "It forms a single wave, which, beginning to rise about the middle of May, gradually attains its highest point in the forty-third week, or the end of October, and then as gradually subsides to the end of March." In point of fact, the increase of the curve above the mean line mainly takes place in September, the mortality maintains its chief excess during October and November, and rapidly falls to the mean line during December. The present may therefore be considered as the precise season for the maximum scarlet fever mortality. Bearing this fact in mind, the excess of mortality from this disease recently reported in London by the Registrar-General affords no sufficient ground for alarm. During the first half of October 149 fatal cases of scarlet fever were registered in London; this number exceeded by but 19 the corrected average number in the corresponding week of the last ten years. It is true that on Saturday last 480 cases of scarlet fever were under treatment in five of the Metropolitan Asylum Hospitals, in addition to 130 in the London Fever Hospital. It may, however, be very misleading to attempt to estimate the extent of an epidemic from the number under hospital treatment. The managers of the Metropolitan Asylum District have placed at the disposal of the public an amount of hospital accommodation, during this scarlet fever season, considerably in excess of that available in recent corresponding periods. It may well be that at the present time an exceptionally large proportion of the cases of scarlet fever in London is under hospital treatment. It is quite certain, however, that those in hospital bear no known or fixed proportion to the total cases at any given time. It is worth noting, moreover, as evidence that the present type of the disease is not unusually severe, that of the 291 hospital cases of scarlet fever discharged by recovery or death during the past six weeks, the proportion of mortality has scarcely averaged more than 10 per cent., notwithstanding an exceptionally high rate of mortality in the Homerton Hospital. Scarlet fever has not been severely epidemic in London since 1875, a fact which it only seems reasonable to attribute in great measure to the controlling influence of the isolation-accommodation afforded by the hospitals of the Metropolitan Asylum Board.

#### SUNDAY REST FOR PUBLICANS.

THE most popular measure for diminishing drinking seems to be closing public-houses on Sunday. No harm seems likely to accrue to any one from their being now closed a great part of the Sunday; and in our opinion great further advantage to the people will result from the general adoption of Mr. Stevenson's Bill for closing them altogether, with perhaps the exception of an hour in London and one or two other large places. Four hundred towns, in various parts of England and Wales, have been canvassed, with the result of showing eight to one in favour of closing the whole Sunday. It is a curious fact that many of the class who use, and who even abuse, the public-house on Sundays vote for its being closed.

## THE MACCLESFIELD INFIRMARY.

WE regret to find from a newspaper report that there has been for some time past serious friction in the working of the Macclesfield Infirmary, which has at length culminated in the resignation of the house-surgeon and the dismissal of the matron. A special meeting of the Governors of the Hospital was held on Friday, October 13th, when a letter was read from Mr. Horace Elliott, the house-surgeon, in which he complained that, in spite of his position as responsible head of the institution and the assurance that his authority would be upheld, he found himself without any authority at all, and unable to resist undue interference with the patients on the part of the matron and servants. He further states that, contrary to his wishes, a patient who had received serious injuries to the head, and upon whom double amputation at the shoulder-joint had been performed, was left for some hours, the night after the injury, in the care of a "charwoman, ignorant of nursing, and on another occasion, some days afterwards, the patient was left in charge of a young and inexperienced ward maid, who had only recently come to the infirmary, and had other work to do in addition." Mr. Elliott adds, "On discovering this, I sent a nurse to take charge of the case, and she was ordered away soon after by the matron." It is also alleged that the matron has even attempted "to take the treatment of cases out of the hands of the medical staff by giving a patient some remedy of her own." Other irregularities were also spoken of. We learn that a long and serious discussion took place, and that ultimately Mr. Elliott's resignation was accepted, and the matron was dismissed on Monday last. From the facts before us it is clear that Mr. Elliott acted rightly in resigning his post; and we cannot question the justice of the decision of the Governors; but it is a matter for very serious regret that the Board of Management allowed matters to assume such an acute phase. It is evident that not the particular officials, but the regulations of the institution and the division of responsibility, have been to blame; and ere they can appeal to the support of the charitable public, or the confidence of the suffering poor, efficient steps must be taken to prevent the recurrence of such disorderly conduct. Of one thing there can be no doubt, that medical officers only should, under any circumstances, interfere with the treatment of the patients, and that the house-surgeon should be able to command efficient nursing for all serious cases of accident or illness. Nothing more effectually checks the support of the charitable than such exhibitions of faulty management as that which has taken place at Macclesfield.

## THE PROGRESS OF CHOLERA.

THE prevalence of cholera in the Eastern Archipelago gives prominence to certain views which M. Proust, who was the delegate of the Paris Academy of Medicine at the recent Health Congress of Geneva, has, since his return to France, expressed to the Academy. M. Proust believes there are grounds, if not for alarm, yet for the observance of strict precautions, in view of the possibility of the importation of cholera into Europe from the East. In 1832 and in 1847 the disease travelled in a westward direction across Afghanistan, Persia, Syria, and the valley of the Danube; but it is to the alternative and shorter route up the Red Sea and through the Suez Canal into the Mediterranean that M. Proust directs more pressing attention. Our neighbours, the French, have all along insisted on the necessity for quarantine measures with a view of protecting the Mediterranean ports against infection imported along the maritime canal; we, on the other hand, have maintained that if a proper system of inspection, together with the provision of means of isolation, were provided, quarantine measures as

ordinarily understood would not be needed. If one or more cases of cholera were detected on board a ship entering the Suez Canal, every necessary and reasonable precaution would be observed if the patients were isolated on shore, and if, after such measures of disinfection as were found necessary, the vessel were allowed to proceed. The lengthened retention of a vessel under such circumstances, with its crew and complement of passengers, cannot, we believe, be justified.

## NEW COTTAGE HOSPITALS.

It is gratifying to have to record this week the addition of two Cottage Hospitals to the list of these excellent institutions already in existence in the land. Of one of these the memorial stones were laid at Harrogate on September 28th last, by F. B. Greenwood, Esq., J.P., in the presence of an influential company of the residents of the town. In the course of the proceedings, Dr. Neville Williams, honorary medical officer of the hospital, gave a sketch of the circumstances connected with the origin of the proposal to erect a building capable of accommodating from fifteen to eighteen patients. The need for such an institution having become recognised, a lady came forward with a donation of £1000, Mr. Greenwood gave a plot of ground, and a canvass of the town for subscriptions was so successful as to put the committee in possession of funds sufficient to enable them to commence operations at once without fear of becoming very deeply in debt. The building, it appears, will be constructed on the pavilion system, all the details being in accordance with the scientific requirements of the day.

Another hospital of the kind will be opened at Norwood by the Lord Mayor to-day (Saturday). It is situated in Hermitage-road, Central-hill, and is built to meet the requirements of parts of Lambeth, Camberwell, and Croydon, together with the hamlet of Penge—districts which contain a population of 30,000. It is a purely local enterprise, having been built through the exertions and under the superintendence of a committee appointed by the residents in 1880. The cost of the building, which is in the Queen Anne style, intermixed with Gothic and Early English, and will hold fourteen beds, is £2000, which is already subscribed, and a further sum of £425 is also promised towards the purchase of furniture and medical appliances. Subscriptions are promised sufficient to maintain eight beds, and it is intended to form an endowment fund of £2000, to provide for the ground-rent, repairs, and the remaining beds.

## PATHOLOGICAL SOCIETY OF LONDON.

LAST year a committee of the Pathological Society was appointed to obtain further details, where possible, of the cases which had been presented to the Society in an incomplete form. Many months have now elapsed since this committee issued circulars requesting further information from exhibitors, and they are desirous of receiving replies with the necessary details as soon as possible. To this end we beg to call attention to the subject.

## AFGHAN AND ZULU MEMORIAL FUND.

AT a meeting of the committee of the medical officers, "Afghan and Zulu Memorial Fund," held at 6, Whitehall-yard, on the 14th inst., present Surgeon-Generals Thomas Longmore, C.B., J. Sinclair, and Deputy Surgeon-General J. O'Neil, C.B., it was decided to close the subscription list on December 31st, 1882. Officers who have not sent in their contributions are requested to do so before that date to the honorary secretary, Brigade-Surgeon Alfred Clarke, Royal Military College, Sandhurst, Farnborough. The amount subscribed up to date is £450.

## SMALL-POX AND PERSONAL LIBERTY IN CAPE COLONY.

POLITICIANS of Mr. Peter Taylor's stamp should study the agitation now felt in the various communities of the Cape by the presence or by the proximity of small-pox. A community in such a state is delivered from the absurd mental condition in which all sense of proportion is lost, in which the occurrence of a rash or an erysipelas is held to counteract the advantages of national compulsory vaccination. After all, there is one terrible guarantee that civilised communities have against the prevalence of such doctrines as Mr. Taylor represents in the House of Commons, and that is the disease of small-pox itself, with its unspeakable hideousness, loathsomeness, and mortality, to say nothing of its secondary and lasting consequences. Cape Town, to judge from the *Cape Times*, is in a very bad way from the prevalence of filth and filthy people in it, and the outbreak of small-pox in such a country is a terror to Port Elizabeth and other places in the colony and in South Africa generally. These places are so much horrified at the risk of small-pox coming to them from the Cape and spreading, that they are making havoc of individual liberty. Persons daring to have small-pox and to conceal it are liable to be visited under the Contagious or Infectious Disease Act No. 1, of 1856, now in force in Port Elizabeth by proclamation of His Excellency the Governor, and to be removed with all possible care and speed to any hospital open for the purpose. Persons in any town, village, or other locality in which the Act is in force may be required by two persons authorised by the Act to give proof of being vaccinated; and on failing to do so, and on refusing to be revaccinated, may be removed or detained in any building or place used as a lazaretto, there to remain until this Act shall be withdrawn, or until he shall allow himself to be vaccinated. The good people of Port Elizabeth, in public meeting assembled, have freely endorsed the action of the Governor and of the Town Council in taking strict measures, and only regret that, being under the Government of the Cape, they cannot go further, like the authorities of Natal, and impose a heavy quarantine of fourteen days on vessels arriving from Table Bay or the docks of Cape Town. We do not approve of such an extreme measure as this. But it may safely be assumed that, even if in a civilised community anti-vaccinationists could triumph for a time when small-pox is in abeyance, their triumph would be short-lived. One case of small-pox in a community uncontrolled by law and medical science, would work results, compared with which the effects of an occasional irregular or careless vaccination are a mere fleabite. By all means let great precautions be taken against these, but let us avoid the insanity of disproportion, and of two evils choose the least.

## THE HAMPSTEAD HOSPITAL.

AT the meeting of the Metropolitan Asylums Board on the 14th inst., a letter was read from the Local Government Board giving the managers authority, if the counsel's opinion was favourable, to the opening of the Hampstead Hospital, and to take all necessary steps to refit the institution, to which it was resolved to appoint Dr. Collie as superintendent.

## CINCHONA CULTIVATION IN JAMAICA.

WE are glad to learn from the report of Mr. Morris, director of the public gardens in Jamaica, that the cinchona cultivation in the island continues to promise well. The chief event of last year was the introduction of the valuable *Cinchona Ledgeriana*, which is the most precious of all known species. A small quantity of seed, less than half an ounce, was received, and from it 14,437 seedlings were raised, a considerable proportion of which will shortly be ready for

planting out. The demand for young plants from private cultivators continued large, amounting to nearly 50,000 plants and 83 oz. of seed. An analysis, by Mr. J. E. Howard, of some specimens of Jamaica-grown bark gave very satisfactory results. Only one shipment was made, which realised a good price in the London market, the best selling for 7s. 8d. per lb.

## ALLAHABAD MEDICAL SOCIETY.

A MEDICAL SOCIETY has been founded at Allahabad, and has already published three numbers of its *Proceedings*, the August number being now before us. Meetings are held monthly, the president being Deputy Surgeon-General Hindley; Hon. Secretaries, Surgeons Shirley Deakin and Sherman Bigg. At the meeting in August two papers were read bearing on the education of European children in India, and the great sickness prevalent amongst them in consequence of their enforced residence in the plains during the hot season. One paper was read by Dr. McReddie, the other by Mr. Deakin, and a resolution was unanimously passed by the meeting to the effect "that the education of European children in the plains of India during the hot weather is detrimental to their physical and mental development, and that it is desirable that they should be removed from the plains, at least during the hot weather, to schools in the hills, at new stations if possible."

## TYPHOID FEVER IN PARIS.

IT appears from the official return issued by the municipal authorities in Paris that no fewer than 250 fatal cases of typhoid fever were recorded in that city during the week ending the 12th inst. The numbers in the three preceding weeks had been 53, 57, and 134 respectively. The prevalence of the disease appears to be very general throughout the city, as only 14 of the 80 "quartiers," into which the city is divided, were free from a fatal case during the week ending the 12th inst., although 100 of the 250 deaths registered from this disease were returned from public institutions, mainly hospitals. During the first three quarters of this year the deaths from typhoid fever in Paris were respectively 436, 553, and 738; in all 1727 in the nine months ending September. The number of fatal cases of this disease during the same period in London, with a population nearly double that of Paris, was only 609, equal to a rate of mortality only one-fifth of that recorded in Paris.

## THE LATE DR. PEELE OF DUBLIN.

DR. EDWARD PEELE died last year from typhus fever after a short illness. He was a general favourite and some of his friends have erected a beautiful window to his memory in St. Patrick's Cathedral. The window represents three scenes from the parable of the Good Samaritan—the traveller falling among thieves, the Good Samaritan binding up his wounds, and his being brought to the inn. Above is the text "Go, and do thou likewise." At the base of the window is the following inscription: "To the glory of God, and in loving memory of Edward Peele, of 41, Lower Baginbun street, Dublin, physician and sometime member of the choirs of St. Patrick's and Christ Church Cathedrals; born in Durham, 8th February, 1838; died in Dublin, 18th February, 1881."

AT the Michaelmas Session of the Surrey magistrates on Tuesday recommendations were submitted by the Finance Committee in reference to dividing the county into five districts—to be designated the Metropolitan, the North-Eastern, the South-Eastern, the North-Western, and the South-Western—and appointing three additional coroners. A petition to the Queen was agreed upon.

BELIEVING firmly in the value of medical societies both as a means for advancing science, and not less as of service in promoting social intercourse amongst members of the profession, we are glad to note the success which has attended the formation of the West London Medico-Chirurgical Society. The first meeting was held on the 6th instant at the West London Hospital, under the presidency of Dr. Hart Viner, and Dr. Burney Yeo delivered the address upon the Antiseptic Treatment of Lung Diseases which was published last week in our columns. The large attendance and the vigour with which the subject of the evening was debated promise well for the future of a Society in which much good work is likely to be done.

JAMES WINGATE JOHNSTON, M.D., an Inspector-General of Hospitals and Fleets (retired) and honorary surgeon to the Queen, died on Tuesday at Southsea. He graduated at the University of Glasgow in 1823, and was appointed a fleet surgeon in 1832. He was nominated Deputy Inspector-General of Hospitals in 1847, and served at Jamaica, Walmer, Chatham, and Greenwich. In 1864 he was advanced to the post of Inspector-General, from which he retired in 1870. The deceased received Sir Gilbert Blane's gold medal for "Reports on Medical Topography of the South American Stations" in 1848.

At a recent meeting of the Association of Sanitary Engineers and Surveyors, held at North Shields, a paper was read by Mr. E. C. Buchanan Tudor, on the working of the Canal Boats Act. The author recommended, for the more efficient carrying out of the measure, a systematic periodical inspection of the boats, and that these officials should be appointed by Government for combined districts rather than by local authorities. These recommendations appeared to meet with the approval of the majority of the members present at the meeting. That some amendment of the Act is necessary few will probably be disposed to deny.

In South Africa the epidemic of small-pox continues to spread, the number of cases in the week ending Sept. 26th being larger than in any week since the commencement of the outbreak. A complete panic is said to prevail at Kimberley. Every waggon or coach from Cape Town is examined, and three waggons, containing sixteen passengers, have been quarantined because a case of small-pox was discovered among them. At Riversdale Mr. Justice Smith and the barristers on circuit have been placed in quarantine six miles from the town, because the driver of the Judge's waggon exhibited signs of the disease.

THE Report of the St. John Ambulance Association shows that the work of imparting instruction in the best means of giving first aid to the injured is being prosecuted with considerable zeal and success. During the past year many new centres have been opened, including one in the Riviera; as many as 131 detached classes—other than centres—have been taught, 8065 certificates of proficiency have been issued, and 800 pupils holding certificates have presented themselves for re-examination. The balance-sheet shows an excess of receipts over expenditure to the amount of £500.

THE deaths are announced of Dr. George Capron, for sixty years in practice as an obstetrician in Providence city, R. I.; and of Dr. William Pierson, who was a member of the New Jersey Legislature from 1835 to 1840.

DR. WILLIAM MOORE has been elected President of the College of Physicians in Ireland for the ensuing year.

A RESIDENT of Hastings brought an action last week against a lodging-house keeper in Margate for damages on account of expenses incurred by illness of some members of his family through defective drainage. The case was heard at the Margate County Court, and the plaintiff was nonsuited, the judge ruling that though a house must be fit for occupation when let, a claim for damages caused by illness could not be sustained. Leave, however, was given to re-enter the case if it could be differently framed.

WE understand that H.R.H. the Duke of Albany has consented to preside at the annual dinner to be held in aid of the funds of the National Orphan Home, Ham Common, on the 7th of November next. We would take this opportunity of commending the institution to the sympathies of the charitable.

DR. BYROM BRAMWELL has, by the unanimous vote of the managers, been appointed Pathologist at the Royal Infirmary, Edinburgh, in the vacancy caused by the translation of Dr. Hamilton to the Pathological Chair at Aberdeen. Dr. Mac Gillivray was at the same meeting elected Assistant-Surgeon to the Infirmary.

A MEETING of the members of the Senate of the University of Cambridge, and others, is convened for the 21st inst. (this day) at 4.30 P.M. in the Lecture-room of Comparative Anatomy to take steps to establish in the university a memorial to the late Professor Balfour.

It is reported that the Peculiar People have founded a Home, in which they hope to demonstrate the practicability of their peculiar doctrine that sick persons may dispense with medical treatment, and may be cured by prayer and the laying-on of hands.

It is stated that the ceremony of conferring the degrees and honours obtained at the recent examinations at the Royal University of Ireland will take place on the 8th prox. His Grace the Duke of Abercorn, Chancellor of the University, will preside.

It is rumoured (says the *Boston Medical and Surgical Journal*) that Dr. Oliver Wendell Holmes, Parkman Professor of Anatomy in the Harvard Medical School, is about to resign the professorship which he has so long adorned.

DR. AQUILLA SMITH has been re-elected a Representative of the College of Physicians in Ireland, on the General Medical Council.

THE Companionship of the Order of St. Michael and St. George has been conferred on James Mackie, M.B., Physician to Her Majesty's Consulate at Alexandria.

## Public Health and Poor Law.

### LOCAL GOVERNMENT DEPARTMENT.

#### REPORTS OF MEDICAL OFFICERS OF HEALTH.

*Wandsworth.*—In a joint report by the several medical officers of health for the parishes comprised in the Wandsworth district it is stated that in 1881 the population was 212,492, the birth-rate being 35.6 and the death-rate 17.1 per 1000. The general health of the district was good except in so far as it was affected by the prevalence of small-pox, and even as regards this disease it is noted that a comparative immunity was experienced, this result being attributed to the energetic measures of vaccination, isolation, and disinfection.

tion which had been carried out. The infantile death-rate is stated to have been small, but it being calculated on the total deaths instead of on the births, the fact is not at first sight apparent to those unacquainted with the statistics as to births. When so calculated the deaths under one year of age amount to 14 per cent. of the births. A separate report is appended by each medical officer of health with reference to his own part of the district, and Mr. Kempster in describing the epidemic of small-pox in Battersea East gives an account of its commencement at Nine Elms. The first patient attacked in this locality was an unvaccinated child whose parents had purposely moved about in order to evade the vigilance of the vaccination officer, the result being that the child's life was sacrificed and its illness led to seven other attacks of the disease.

*Glanford Brigg.*—Mr. J. B. Moxon's annual report for 1881 on the rural sanitary district of Glanford Brigg contains a good deal of matter which is of local and general interest. In a population of 28,569 the death-rate has been 17 per 1000, and it is noted that together with an increase in population since 1874, there has been a curious redistribution of the inhabitants. Thus, there has been a marked migration from the purely agricultural districts, due to the depressed condition of the farming interest; whereas, in the group of villages affected by the iron manufacture, there has, on the other hand, been a decided increase. The infantile death-rate receives considerable attention, and it is referred to as alarming. We think, however, that this is only so because it is calculated as a percentage on the total deaths, whereas it should be calculated on the total births. If there are an exceptional number of children in a district and very few old people, the number of infantile deaths must, when compared with the total deaths, necessarily be large. But when we examine the births we find there were 1052; there were also 116 deaths under one year of age. This gives a death-rate under one year of 11.0 per cent. of the births, which rate is, as a matter of fact, rather below that of the standard group of rural districts quoted by the Registrar-General, and the low rate is fully explained by Mr. Moxon's statement that the district contains "an exceptionally large proportion of young married people and their children." The question of the provision of means of isolation for such diseases as scarlet fever is dealt with in a manner rather implying the inapplicability of infectious hospitals to rural districts. We admit that public opinion is not yet prepared for such use of these hospitals as will fully secure rural districts against the spread of infection, but it is essentially scarlet fever which needs isolation in these districts, and the report recently issued by the Local Government Board on the use of infectious hospitals goes most emphatically to show that when suitable buildings are provided, the necessary educational process has rapid effect, and that the number of parents willing to part with their children has steadily increased, until the infantile admissions have been found to surpass all anticipations. If, however, the isolation is not energetically carried out in the early stage, we freely admit that it becomes to a great extent useless, as in the case of Hull quoted by Mr. Moxon, and this because such hospitals are not intended to deal with epidemics, but rather to prevent them by the immediate isolation of first attacks. An active supervision of conditions affecting health is evidently maintained, and apart from delays in agricultural areas where the financial depression has been very marked, steady progress may be regarded as having been made.

*Belfast.*—During the four weeks ending 23rd September the births registered numbered 461, and the deaths 355, or a natural increase of 106 individuals. The average death-rate from all diseases was 22.1, from lung affections 6.5, and from zymotic diseases 4.6. During the past month the public health has been satisfactory, the town having been free from any serious epidemic disease. A few cases of typhus were reported, but as only two cases proved fatal, the disease was not of a very bad type. During September 5 cases of small-pox were removed to the hospital for contagious diseases, and every precaution taken to prevent the spread of the contagion.

*Cork.*—During the four weeks ending September 9th the births registered amounted to 164, being equal to a rate of 27.20 per 1000. The deaths numbered 100, or 18.20, but deducting the deaths (23) occurring in the workhouse, the urban death-rate will then be 14.6, and from infectious diseases 1.0. These returns contrast favourably with those for the corresponding period last year, and there has also

been a decided diminution in the amount of fever of every description in the city.

#### THE SANITARY STATE OF GALGATE.

The village of Galgate, in the Lancaster rural sanitary district, has been visited by Dr. Barry on behalf of the Local Government Board. Typhoid fever has been prevalent there, and it was found that the water-supply is derived from wells which are irremediably polluted, and that, notwithstanding the provision of public means of sewerage, the house drainage is defective in the extreme, and nuisances of an excremental character are numerous.

The Wrexham Corporation has given instructions for the preparation of plans for a new sewerage scheme, with the view of ending the dispute between them and Lieutenant-Colonel Jones, tenant of Borough Farm, and to prevent the pollution of the Dee complained of by the Chester Corporation.

An order has been received at Barking by Mr. Goldicott (steward to Sir Edward Hulse, Bart., lord of the manor), from the Local Government Board, informing him that the Board has formed the town ward of Barking into a Local Government district.

#### VITAL STATISTICS.

##### HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns, 5524 births and 3522 deaths were registered during the week ending the 14th inst. The annual death-rate in these towns, which had not exceeded 20.6 and 19.9 per 1000 in the two preceding weeks, rose last week to 21.7. The lowest death-rates in these towns last week were 12.6 in Plymouth, 14.8 in Brighton, 15.0 in Wolverhampton, and 15.4 in Bradford. The rates in the other towns ranged upwards to 27.2 in Leeds, 28.0 in Liverpool, 28.9 in Sunderland, and 34.3 in Oldham. The deaths referred to the principal zymotic diseases in the twenty-eight towns were 542, and showed an increase of 51 upon the number returned in the previous week; 147 resulted from diarrhoea, 137 from scarlet fever, 87 from "fever," 67 from measles, 64 from whooping-cough, 33 from diphtheria, and 7 from small-pox. The lowest death-rates from these diseases were recorded in Brighton and Norwich, and the highest in Cardiff and Sunderland. Scarlet fever showed the largest proportional fatality in Leeds, Sheffield, and Leicester; measles in Cardiff and Sunderland; whooping-cough in Birkenhead and Blackburn; and "fever" in Leeds, Birkenhead, and Portsmouth. So many as 26 deaths from diphtheria occurred in London, whereas but 7 were recorded in the twenty-seven provincial towns, with a somewhat larger aggregate population. Small-pox caused 4 deaths in London, 2 in Newcastle-upon-Tyne, and one in Manchester. The number of small-pox patients in the metropolitan asylum hospitals, which had been 80 and 79 on the two preceding Saturdays, rose to 84 on Saturday last; 13 new cases of small-pox were admitted to these hospitals during the week, against 17 and 14 in the two previous weeks. The Highgate small-pox hospital contained 11 patients on Saturday last, 7 new cases having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 300 and 253 in the two preceding weeks rose to 302 last week, and exceeded the corrected weekly average by 26. The causes of 82, or 2.3 per cent., of the deaths in the twenty-eight towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leicester, Derby, Birkenhead, Halifax, and Cardiff; while the proportions of uncertified deaths were largest in Wolverhampton, Salford, Oldham, Huddersfield, and Hull.

##### HEALTH OF SCOTCH TOWNS.

The annual death-rate in the eight Scotch towns, which in the three preceding weeks, had increased from 18.1 to 22.3 per 1000 declined again to 19.2 in the week ending the 14th inst.; this rate was 2.5 below the mean rate during the week in the twenty-eight large English towns. The deaths referred to the principal zymotic diseases in these Scotch towns, which had been 117 and 107 in the two previous weeks, further declined last week to 99; these included 26 from diarrhoea, 20 from diphtheria, 19 from whooping-cough, 18 from scarlet fever, 9 from measles, 7

from "fever," and not one from small-pox. The death-rate from these principal zymotic diseases averaged 4.2 per 1000 in the eight towns, and exceeded by 0.9 the rate from the same diseases in the large English towns. The 26 deaths attributed to diarrhoea showed a decline of 10 from those in the previous week, and were 11 below the number in the corresponding week of last year. The 20 deaths referred to diphtheria exceeded those in the previous week by 3, and included 11 in Glasgow, and 5 in Greenock. The 19 fatal cases of whooping-cough included 16 in Glasgow, and were 4 fewer than those returned in the previous week. The deaths from scarlet fever, which had been 22 and 17 in the two previous weeks, were 18 last week, of which 9 occurred in Glasgow, 6 in Edinburgh, and 2 in Dundee. The deaths referred to acute diseases of the lungs in the eight towns, which had been 102 in each of the two preceding weeks, declined to 100 last week.

#### HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 26.1, 23.7, and 19.9 per 1000 in the three preceding weeks, rose again to 24.4 in the week ending the 14th inst. During last quarter the death-rate in the city averaged 23.1 per 1000, against 18.6 in London and 17.8 in Edinburgh. The 163 deaths in Dublin last week showed an increase of 30 upon the low number in the previous week, and included 6 which were referred to diarrhoea, 4 to "fever," 2 to whooping-cough, and not one either to small-pox, measles, scarlet fever, or diphtheria. Thus 12 deaths resulted from these principal zymotic diseases, against numbers declining steadily from 28 to 14 in the four preceding weeks; they were equal to an annual rate of 1.8 per 1000, while the rate from the same diseases was equal to 3.1 both in London and Edinburgh. The 6 fatal cases of diarrhoea, showed a further decline from the numbers returned in the six preceding weeks. The deaths referred to "fever," which had been but 1 and 2 in the two previous weeks, further rose to 4 last week. The fatal cases of whooping-cough, on the other hand, showed a decline of 2. The deaths both of infants and of elderly persons exceeded the numbers returned in recent weeks. The causes of 17, or nearly 11 per cent., of the deaths registered during the week were not certified.

#### THE SERVICES.

RIFLE VOLUNTEERS.—2nd Derbyshire: William Sandham Symes, Gent., to be Acting Surgeon. 1st Essex: Albert William Wallis, Gent., to be Acting Surgeon. 24th Middlesex: Charles Drummond Moutray, Gent., B.A., to be Acting Surgeon.

ADMIRALTY.—In accordance with the provisions of Her Majesty's Order in Council of 1st April, 1881, Inspector-General of Hospitals and Fleets John Bernard has been placed on the Retired List of his rank.

The following appointments have been made:—Surgeon Thomas D. Popham, M.D., to the *Constance*; Fleet Surgeon Alexander Turnbull, for service at the Admiralty.

#### WILLS AND BEQUESTS.

THE will of Alfred James Bannister, M.D., M.R.C.S., of 11, Addison-terrace, Notting-hill, who died on Aug. 22nd last, at Great Malvern, was proved on the 22nd ult. by Mr. C. H. Johnson, one of the executors, the value of the personal estate amounting to over £13,000. The testator wishes his practice to be sold for a year's purchase, if possible, taking the average of the last three years; the purchaser to have the option of buying the lease of his house, but the money for the latter is to be paid down. To his wife he gives his furniture and household effects, and the residue of his property is to be held upon trust for her for life or widowhood, and then for his children.

The Scotch Confirmation of the holograph will of George Dickie, M.D., Emeritus Professor of Botany in the University of Aberdeen, who died on July 15th last, granted to Mrs. Agnes Williamson Low, or Dickie, the widow and

executrix nominate, was sealed in London on the 2nd ult., the value of the personal estate in England and Scotland exceeding £8000.

The will of William Drysdale Tennant, M.D., of 30, Lambert-road, Brixton-rise, who died on August 11th last, was proved on the 22nd ult. by Mrs. Sophia Tennant, the widow and sole executrix, the value of the personal estate amounting to £5000. The testator gives, devises, and bequeaths all his estate and effects, both real and personal, to his wife for her own use and benefit absolutely.

The following legacies have recently been left to hospitals and other medical charities:—Miss Mary Ann Barbara Holburne, of 10, Cavendish-crescent, Bath, £100 each to the Royal United Hospital, Bath, and the Mineral Water Hospital, Bath.—Mr. William Henry Le Bas, formerly of Willeeden Paddocks, Kilburn, but late of 16, Wilton-crescent, Knightsbridge, £100 each, free of legacy duty, to the Hospital for Consumption, Fulham-road, and the Hospital for Diseases of the Chest, Victoria-park.—Mr. Charles Patrick Stewart, formerly of Manchester and of 92, Lancaster-gate, engineer and iron founder, but late of Silwood-park, Sunning-hill, Berks, £50 each to St. Mary's Hospital, Paddington, and the Western General Dispensary, Marylebone.—Mr. Leon Emanuel, of Southampton, £19 19s. each to the Jews' Orphan Asylum and Hospital, Norwood, the Southampton Infirmary, and the Southampton Dispensary.—Sir George Howland Beaumont, Bart., of Cole Oxtan Hall, Leicestershire, who directs that his funeral shall be conducted with privacy and simplicity, and, in lieu of the cost that would otherwise be incurred, gives £100 to the Leicester Infirmary.—Mr. Adolph Mosenthal, formerly of 79, Coleman-street, but late of Copthall-buildings and of Bayswater, merchant, £300 to be distributed by his executors among hospitals and other charitable institutions in England and the Cape of Good Hope.—Dr. Wm. Thompson, late of Lisburn, £100 to the County Antrim Infirmary.—Mr. John Rogers, £50 to the Belfast Royal Hospital.

### Correspondence.

"Audi alteram partem."

#### THE TREATMENT OF PAUPER LUNATICS.

To the Editor of THE LANCET.

SIR,—As a justice of the peace for this county, and one of the visiting magistrates at one of our largest county lunatic asylums, I find that the mode of dealing with paupers deemed to be of unsound mind might be greatly improved. Between September 1st, 1881, and August 31st last I have had seventy-six persons brought before me in this parish said to be insane. Thirty of these I have sent to asylums, while I have discharged forty-six as sane. With the experience I have gained I am satisfied that we ought to have a receiving house for the county, to which all pauper lunatics, found to be such by the magistrates, should be first sent prior to their being drafted off to the larger asylums. These persons should be retained at this receiving house under supervision until each individual case has developed itself, when the party would be either discharged or drafted off to such asylum as the medical superintendent of the receiving house or hospital may consider as best suited for the particular case. If this step were taken, I believe at least one-quarter of those now passed direct to asylums would never find themselves there at all.

According to the present arrangements, the relieving officer has three days to bring a person reported to him as being of unsound mind before a justice of the peace, who within three days is bound to see such person, and he may remand the case for seven days; but then the question of sanity or insanity must be determined—that is, whether the party is to be sent to an asylum or not. It frequently happens that during the seven days a manifest improvement has taken place in the state of the patient, but not quite to such an extent as to warrant discharge. When such is the case, there is no alternative but an asylum, and the party becomes in the eye of the law a lunatic. The temporary removal of such cases to a receiving hospital would meet the

object I have in view, and save the county a heavy and increasing expenditure.

The Commissioners in Lunacy state there is a steady annual increase of 400 lunatics, after allowing for death and discharged, in this county, exclusive of the City, and, as commissioners restrict the three county asylums, Hanwell, Colney Hatch, and Banstead to 2000 each, this annual increase will involve the erection of a new asylum every five years. The cost of the maintenance of our lunatics will therefore steadily increase, unless we pursue at once some direct course such as proposed, and also classify our patients in our asylums, according to the nature of their individual cases, upon some fixed principle, and cease to keep them together in the same wards irrespective of their condition.

I addressed you in November last upon the desirability of having a separate hospital for women suffering from diseases attendant upon childbirth. As I pointed out, it is hard to visit these poor women with the brand of insanity because they are temporarily affected with a disease only requiring care and attention to restore them to health.

I cannot too strongly urge the necessity of classification; but such is the crowded state of our asylums that such an arrangement is impossible; and as the question of additional accommodation will shortly arise, I would make a beginning by erecting a receiving hospital for 200 males and 500 females; also a hospital for female cases—say 200—and an asylum for 400 males and 600 females, so constructed as to allow a classification. I believe all these arrangements could be carried out under the existing Acts of Parliament.

I am, Sir, your obedient servant,

Chelsea, Oct. 13th, 1882.

H. W. GORDON.

## POISONOUS DOSES OF MALE FERN.

To the Editor of THE LANCET.

SIR,—The lamentable occurrence reported in the *Ceylon Observer*, and commented on in your last number, induces me to offer a few remarks. Probably there is no practitioner in England who would think of prescribing six drachms of the ethereal extract of male fern for a single dose, and still less likely would he be to follow it up at a short interval by a second dose of equal amount. Having on several hundred occasions prescribed male fern in cases of tapeworm, it may encourage others who have not enjoyed equal opportunities if I state that doses not exceeding one drachm never occasioned serious mischief; and only in four instances within this experience did any untoward symptoms show themselves. In one case, that of an M.P., where two separate one-drachm doses were given, a slight attack of jaundice followed; and in another case, that of a little boy about seven years old, two half-drachm doses produced mental confusion. In both cases the symptoms soon passed off. I have seen no permanent ill effects from male fern, but I have heard of one instance in which three drachms of the extract sufficed to produce alarming symptoms. It would be a pity if this valuable remedy, the preparation of which costs pharmacutists so much trouble, should be discarded on account of its fatal employment in the Ceylon patient. In many cases of five, ten, and even fifteen years' standing, I have found it efficacious; and in one instance, where a gentleman had been treated, off and on, for more than sixteen years, a second half-drachm dose of the extract brought away the so-called *head* of the worm. In a little girl of two years old, the administration of ten drops finally effected the same result. I have tried most of the other vermifuges recommended in the *Pharmacopœia*, but out of several dozen *heads* of tapeworms in my possession not more than two of them were expelled by their agency. The male fern extract brought away all the others.

I am, Sir, yours truly,

T. SPENCER COBBOLD, M.D., F.R.S.

London, Oct. 16th, 1882.

## "BANGOR FEVER AND THE WATER SERVICE"

To the Editor of THE LANCET.

SIR,—The attention of the Bangor Local Board has been called to an article which appeared in THE LANCET of Sept. 30th, respecting the epidemic of typhoid fever at Bangor, in which it is stated that "it is much to be deplored that the Local Board of Health set their own opinion against that of their medical officer of health, and declined to accept

his view that water pollution was the real cause of the outbreak. Had they at the first outset acted on the advice of their proper adviser in such matters much sickness and distress might have been avoided."

I am directed to state that the article in question appears to the Board to be simply a continuation of the unworthy and utterly uncalled for attacks made on them at Rhyl a few weeks ago by THE LANCET's friends and patrons, and the Board feel that it is only fair to themselves and the public to submit the following questions—viz., (1) Will THE LANCET be pleased to point out any particular order or suggestion of Dr. Rees or the Local Government Board, directly bearing upon the epidemic, with a view of checking the same, that this board did not attend to and that promptly? (2) If this board had been in perfect accord with Dr. Rees' theory, and believed that the water was contaminated, could they have done one  *iota* more than they did to stay its ill effects? (3) In the serious emergency, was not every action tending directly to prevent the spread of the epidemic done at the suggestion of members of the Board or their clerk and surveyor prior to Dr. Rees' instructions for fumigating the sewers on Aug. 20th.

I am also directed to state that it is the opinion of the Board that if the writers in THE LANCET are as anxious to be truthful and accurate as they seem to be to damage the reputation of a public body by such vile aspersions, they will no doubt make further inquiries into this matter, and the Board have no fear of the result being in any one particular materially unfavourable to their proceedings.

I am, Sir, yours respectfully,

Bangor Local Board of Health, Oct. 5th, 1882.

JOHN GILL.

\*. \* It is not our custom to insert letters containing strong epithets and accusations of untruthfulness; but the occasion may be regarded as an exceptional one, and hence, in this instance, we depart from our usual practice. We would, however, express a hope that Mr. Gill is in error in attributing to the Local Board of Health for Bangor the language he has seen fit to embody in his letter. With regard to Mr. Gill's questions, we prefer answering them by references to the official report which Dr. Barry has presented to the Local Government Board. 1. As to the alleged prompt action in carrying out suggestions as to checking the disease. From Dr. Barry's report it is evident that Mr. Rees, the medical officer of health, suspected water pollution as far back as June 13th; that the sanitary authority, instead of "accepting the opinion of their medical officer of health that the primary cause of the outbreak was to be found in the water...., sought it in meteorological and other obscure directions"; and that having received a favourable analysis of some samples, "they at once concluded that the danger could not lie in that direction, in spite of Mr. Rees' statement that the specific infection of enteric fever could not be detected by analysis." 2. As to what more could have been done by the authority to stay the progress of the disease, we note that Dr. Barry, being in complete accord with the views expressed by Mr. Rees as to the cause of the epidemic, left with the authority on August 3rd a written memorandum embodying the "immediate steps" necessary for adoption. After an interval of some six weeks he reports on the 20th of September his regret at the "considerable delay" which had taken place "in carrying out some of the more important" of these measures, and he instances two serious examples. Thus, the "renewal of the old filtering material" (believed to be specifically contaminated) "was not ordered by the sanitary authority until August 17th, and the work was not executed until the 5th of September." And again, "the provision of efficient ventilation for the main sewers" (the lack of which was leading to the entrance of specifically poisoned air into dwellings) "to the necessity for which," says Dr. Barry, "I had drawn particular attention on the 3rd August, was only ordered by the sanitary authority to be done to a limited extent on the 31st August, and not fully until the 7th September." 3. We have on no occasion referred to the instructions given on August 20th as to the fumigation of the sewers. What we have referred to was

the unfortunate delay in dealing "promptly" (to use Mr. Gill's own term) with the conditions tending to the spread of this disastrous epidemic, and we need not go beyond Dr. Barry's official report for a full confirmation of what we have stated. We have received a letter from Mr. Hugh Rees, written in reply to that of Mr. Gill published in the local papers. The communication, which is too long for insertion, entirely confirms the statements we have thought it right to make in regard to this matter.—ED. L.

### PROFESSOR PACINI'S LETTER.

To the Editor of THE LANCET.

SIR,—On receiving my copy of your last impression I found, to my great regret, that some misprints in the copy of Professor Pacini's letter had escaped my notice when correcting the proof. I shall esteem it a favour if you will allow me now to correct the following *errata*:—Line 2 of the letter, for "ella" read *Ella*; line 4, for "dictro" read *dictro*; line 11, for "attribuarla" read *attribuiria*; line 14, for "morte" read *morti*; line 16, insert "dei" before *Lincei*; line 18, omit the apostrophe after "del"; at the conclusion, for "afft" read *affs*.—I am, Sir, yours truly,

Savile-row, Oct. 17th, 1882.

GEORGE JOHNSON.

### A SIMPLE OPERATION FOR VARICOCELE.

To the Editor of THE LANCET.

SIR,—I have for some time adopted a mode of ligature for varicocele which has been found to answer very well. It is a modification of M. Ricord's plan, and will be readily understood by the accompanying diagram. The skin of the

projecting. A second needle is now passed in the opposite direction between the veins and the skin, leaving a loop also. The free ends of the ligature are then passed one under and one over each loop, drawn up tight, tied, and cut off short, the knot on each side sinking subcutaneously. The after results are the same as in the cases described by Mr. A. Barker. The performance of it is quick, simple, and efficient.

I am, Sir, your obedient servant,

Hanley, Oct. 10th, 1882.

W. DUNNETT SPANTON.

### "THE QUEEN'S UNIVERSITY DEGREES."

To the Editor of THE LANCET.

SIR,—My attention has just been drawn to a letter in your issue of the 7th inst., in which Dr. A. H. Jacob admits having stated to the Royal Medical Commission that "a student attending a Queen's College may obtain all the lectures necessary for a Queen's University degree in two years," and refers to the Queen's University of Ireland calendar as proving that "two courses of lectures at most were required by the University in any subject and these were readily obtained in two years." Now the fact that two courses at most were required is undoubted, but this does not prove that all the lectures could be taken out in two years, and in a Queen's College. As a matter of personal experience, I may say that I tried at Cork to take lectures in anatomy and medicine in the same year, and (after paying my fees, a fact which may have aided my memory) found I could not do so, as both lectures were delivered at noon and on the same days (*vide* Queen's College of Cork Calendar). Now, as two courses of lectures in anatomy are required and one in medicine Dr. Jacob's general statement about the Queen's Colleges falls to the ground. Other instances of lectures "clashing" could easily be given, and to show the strictness with which the "two-thirds" rule is carried out let me add that I have known a student who required a certificate of having attended fifty lectures, to be refused any certificate as he had attended only 75 lectures out of a course of 120, and the incident was not considered at all singular.

Passing over the curious statement that twenty-four months' hospital attendance is equivalent to two years and three months, which, as the hospital year has only nine months, seems very strange arithmetic, we read "that difficulty was *always* easily adjusted with the hospital authorities." The only meaning I can attach to these words is that the hospital authorities conspired with the students to cheat the Queen's University of Ireland by means of false certificates, and that this odious charge is not true always must be known to every medical man, so I content myself with denying that such a thing could be done in the Cork hospitals, and shall be glad to hear what evidence Dr. Jacob has of its feasibility in the other hospitals which could be attended by a "student attending a Queen's college"—i.e., Belfast or Galway. Judging from an uncontradicted letter in a recent number of THE LANCET, in which it was stated that apothecaries' apprentices obtain bogus certificates from certain hospitals or schools, and especially from the careless way Dr. Jacob speaks of so grave an offence, it might be perpetrated in Dublin, but then a student cannot be in Dublin and "attending a Queen's College" at the same time. And if the Queen's University were cheated why should Dr. Jacob think the crimes of hospitals faults in its curriculum? Could even he, with his evident experience, distinguish a false from a true certificate?

Dr. Jacob concludes his letter with the remark: "Therefore it is quite true, as I stated, that a student could (and many did) complete his entire curriculum in a couple of months over two years." But this is decidedly not what Dr. Jacob stated, for he told the Commissioners nothing about the "couple of months," and he now omits all reference to the Queen's Colleges. And what can Dr. Jacob mean by "a couple of months," which he elsewhere calls "three months from November," only to add that they were "always" evaded? How could it benefit a student to have completed his curriculum at mid-winter, when the next Queen's University of Ireland examination would be in June?

I have known over 500 Queen's University of Ireland students, and have prepared many of them for examination, and am able to say positively that very few of them, certainly not 5 per cent., took out their College lectures in even three years, that none of them took them out in two years, while the complete curriculum (college and hospital) always occupied four, and frequently five years.

In conclusion, I call upon Dr. Jacob to inspect the time-tables contained in the Queen's College of Cork calendar, and having satisfied himself of the inaccuracy of his statement as to the Queen's Colleges generally, to withdraw it (at least as far as concerns Cork), and further, to inform the Royal Commissioners that what he stated, or meant to have stated, was that the hospitals cheated the Queen's University, so as to enable a student to complete his curriculum in a "couple of months" over two years, and not that a student could honourably complete it within two years, as the Commissioners and the public understood.

I am, Sir, yours faithfully,  
W. R. F.

Oct. 10th, 1882.

\* \* We select this letter for publication out of a number of long ones on the same subject, for which it is impossible to find room. The writer of one of reasonable length says, "I should like to know even one of the many cases which Dr. Jacob has known to have been admitted graduates in medicine long before the lapse of the statutory four years."—ED. L.

### NEWCASTLE-ON-TYNE.

(From our own Correspondent.)

THE annual meeting of our Hospital Sunday Fund was held on the 5th ult., when the committee was glad to be able to again report an increase in the aggregate amount of the 1881 collections over those of 1880. There has been in the year a slight decrease in the sums collected at places of worship, which has been more than covered by the workmen's collections for the Hospital Saturday Fund. The relative figures are as follows:—Places of worship collections, 1880, £1943 5s. 7d.; in 1881, £1911 3s. 7d., a decrease of

32 2s. Workmen's collections in collieries and factories in 1880, £1171 19s. 10d.; in 1881, £1466 5s. 3d., or an increase of £294 5s. 5d.; showing a net increase in 1881 of 262 3s. 6d. The increase in the workmen's collections is highly satisfactory, but the committee appear to be a little timid as to the slight falling-off in the Church collections. On the other hand, it is felt by outsiders that there is but little cause for fear. And may not many of the workmen who formerly gave on the Sunday, now that the Saturday collection is so well established, contribute in that direction? An attempt was made by the movers of the fund to establish a regular collection among the workmen of one penny per week, believing that a considerable sum might be realised in this way; but the project so far has only met with limited success. Upon the whole, our Hospital Sunday Fund has done an immense amount of good since its institution in 1870. I need only mention that it was in that period received and disbursed the noble sum of £36,419 10s. 10d. The committee truly say that "these figures speak for themselves, and are the most eloquent advocates"; and further, they ask that each and all may unite in securing for this year, "the first in our city history, the largest collection ever taken on behalf of our Northern Hospital Sunday Fund." Some anomalies in the distribution of the fund this year, by which the smaller institutions were received a relatively smaller amount than last year, is promised adjustment in the next distribution. Upon the whole, Mr. Richard H. Holmes and the other gentlemen associated with him have worked hard, and deserve much credit for placing, by their management, this great fund on a firm basis.

There is no use in shutting one's eyes to facts, however unpleasant they may be. There has been much talk about small-pox lately both in and out of our city chamber, some asserting strong figures, and others equally strong contradiction, the latter by those who often know least as to what they are talking about. I mean some of our councillors. The small-pox, however, has a very persistent mode of asserting itself, and it is here, and here as in epidemic. Unfortunately it is diffused, a case occurring here and there in various points of the city and the neighbouring borough of Gateshead; so that the enemy is not only "at our gates," but "in our midst." In our own city I have not seen so many bills out as in Gateshead reminding the people of the necessity of vaccination. Every day lost in doing so is much to be regretted in this stage of the epidemic; at present the type is not bad, and mortality is low, but who can say how long this may last? The Rev. Rowland East, Incumbent of St. Andrew's in this city, and who was a qualified medical man before he took holy orders, has written a terse and well-timed letter to the *Daily Express* and other papers here as to the necessity for vaccination, and showing from his own experience as a visiting clergyman its efficacy; this letter to my knowledge has done much good. There is a large class who do not read the newspapers, and these can best be got at by handbills and "mural literature," or house-to-house visitation, but best of all by the vaccinator. A staff of instructed students might in a few days vaccinate some thousands of people. We hear little or no objection urged against vaccination nowadays here, and most practitioners are busily engaged vaccinating the middle classes. If the student scheme were adopted, it would at all events enable them to usefully get rid of some of that exuberant energy of which we had evidence on the opening of the College. The question of expense might be urged against a plan of this nature; but it should be the last thing to be considered by our authorities, seeing that they are about to spend £500 on preliminary drains for the new fever hospital on the Moor, while the Sanitary Congress cost the city £200, and I do not say the money was otherwise than well spent. "Prevention" by way of extensive and systematic revaccination would in the case of small-pox be "better than cure," and I believe also cheaper in the long run.

Much interest is felt here in the coming election at Edinburgh for the post of pathologist to the Royal Infirmary, seeing that Dr. B. Bramwell is a candidate. Dr. Bramwell belongs to an old Tyneside medical family, and before he left the Tyne for "Auld Reekie" he filled the post of pathologist and physician to our infirmary, and it is not too much to say that he filled them well, and that altogether we know him to be a man of high professional attainments.

We are about to have a new institution, and one, I fear, that all our present medical charities can help to

supply with inmates. I mean a Hospital for Incurables. This has been brought about in rather an interesting way. It will be necessary, in the first place, to go back to the reign of King Henry I., when was founded a hospital here called the St. Mary Magdalene, to receive a master, or governor, and brethren, and sisters afflicted with leprosy. In course of time as this disease disappeared the funds were devoted to decayed citizens, with £500 per annum to the master, who was to be a clergyman of the Church of England, with clerical duties appertaining to the office to be performed in the chapel of the hospital. In the course of time the funds increased very much from the enhanced value of the hospital land, and now there is an accumulation of several thousands, with almost a certainty of further increase as leases fall in. The trustees had power in dealing with the income and funds, either in distribution amongst existing charities of the town, or to found and support any new medical charity deemed necessary. They very wisely decided to found a hospital for incurable diseases, and are now casting about for suitable ground for premises. Thus, to as great an extent as is possible in the present day, the funds of this ancient charity are to be appropriated in accordance with the wishes of the pious and thoughtful founder, expressed 700 years ago. In speaking to an American physician at Worcester, he told me he was much struck with the old dates of our institutions. If he sees this notice he will hear of an institution that will carry his mind back to an early period of the history of England surviving and flourishing.

Newcastle-on-Tyne, Oct. 16th, 1882.

## GLASGOW.

(From our own Correspondent.)

JUDGING from the smallness of the number of students presenting themselves for the preliminary examinations at this time, it is anticipated that there will be a marked falling off in the attendance at the University Medical School this session, more especially in the junior classes. Such a state of matters will also probably tell on the extra-mural schools, and for some of them any decided decrease means extinction.

The chloroform question claims a very large share of attention here just now, various unfortunate occurrences, in connexion with anaesthetics, which have taken place lately, having created a kind of panic in many minds. In the Royal Infirmary matters have gone still further, decided action having been taken. Passing by their standing medical committee, the managers have framed a set of rules anent the giving of chloroform, and the conditions under which it must be administered. Of these rules, which come up for consideration and perhaps adoption in the course of a week or two, nothing need be said just now, except that they are of the most extraordinary nature, and certainly not such as are likely to be easily accepted by the surgical staff. Sympathising with the surgeons, the Faculty of Physicians and Surgeons have adopted the very unusual course of calling a *pro re nata* meeting of the Fellows, at which the whole question will be discussed. It is not easy to see what the Faculty in its corporate capacity has to do with the matter, and its deliverances on the subject are awaited with some curiosity.

The contest for the Children's Hospital appointments goes on. Several of the candidates, and especially those to whom rumour assigns the strongest prospects of success, already hold office in one or other of our infirmaries. There is a certain degree of injustice in this, and it causes some irritation; it is held that such appointments should not all go in the same directions. It is understood also to be a *sine qua non* in the case of applicants for the resident medical officership that they should be *non-smokers*.

A correspondence marked by an unusual amount of ornate writing, and to which Dr. W. T. Gairdner has contributed a very excellent letter, is at present going on in the columns of one of our daily papers regarding the pandemonium of noises in which the inhabitants of this city seem content to dwell. Special complaint is made of railway whistling and of the "devils" which many employers use to call their workmen in the morning and after meals. It is to be hoped that something will come of this letter-writing,

though the prospect of such a consummation is not very bright, the principal offenders being the most powerful men in the district.

### SCOTTISH NOTES.

(From our own Correspondent.)

A DIFFICULTY at present exists with regard to the teaching of pathology in Aberdeen. The munificent gift of Sir Erasmus Wilson, by which the chair was endowed, supplied the most conspicuous want of the northern school; but the want of an hospital appointment is anticipated by Professor Hamilton to be a serious hindrance in his work of teaching. Dr. Rodger has for many years acted as pathologist to the infirmary, and his great knowledge of his subject has been made available to the students even while he received but small consideration or support from the university authorities. He is naturally unwilling to vacate his post, and the infirmary directors would hesitate much before they would dispense with the services of one who had so long and so successfully served their interest. Dr. Rodger is quite willing to supply the professor with what material for teaching may be available, but many of the students will feel anxious to have the guidance of more than one lecturer, or at least demonstrator, of pathology, and this might prove a useful check upon a too dogmatic tone on the part of either teacher, a fault not unknown among even professors of pathology. The present arrangement is that which holds good in Edinburgh, and is said there to work very well. In any case it is hoped that arrangements, chiefly in the interest of the students, may be carried out, and it is just possible that Dr. Rodger may accept the position of assistant physician to the infirmary, likely soon to be instituted. It will be unfortunate if Dr. Rodger's wide and accurate knowledge of scientific medicine is not made useful to the students.

In pleading the cause of medical students at the meeting of the University Council last week, Dr. Struthers had a congenial task. The remarkable paucity of bursaries available for medical students at Aberdeen, as compared with those existing in the other faculties, will be seen at a glance on reference to the following table:—

	No. of Students.	No. of Bursaries.	Value of Bursaries.
Faculty of Arts ...	382	282	£5058
Faculty of Divinity ...	32	32	732
Faculty of Medicine ...	335	17	345

Dr. Struthers' purpose in bringing forward this matter was to influence the University Court in favour of making the facts known to friends of the university and of science who might be looking about for some way in which they might benefit deserving youths. The great and increasing cost of medical education, the constant study during summer as well as winter, and the consequent inability of medical students to assist themselves by other work, and the assiduity of the students, were all given as reasons for claiming extraneous aid by means of bursaries. The Council, including the clerical members, two of whom spoke in favour of Dr. Struthers' views, unanimously supported him; and it may be suggested to graduates of Aberdeen that the subject is a very desirable one for their own consideration, as well as one which might with advantage be brought under the notice of wealthy and benevolent patients or friends. There are other universities in Scotland equally anxious to obtain good bursary lists, and £500 devoted to the foundation of such a prize would certainly be money well spent.

The recent local Act for Dundee contains a clause making it obligatory on the part of both doctor and householder to report cases of infectious disease to the authorities. During the first month in which the Act has been in force medical practitioners have reported in 124 cases, householders or persons in charge in 9 cases, and householders and medical men in 12 cases. It is thus seen that householders incline to leave the disagreeable duty to the doctor, but possibly it is more from ignorance than design. Dr. Anderson's first report shows the great prevalence of infectious diseases in Dundee, and the utter inadequacy of the present means of isolation. The authorities seem disposed to take active measures to remedy their former neglect.

The Sanitary Committee at Cupar having declined to

endorse Dr. Whitelaw's recommendation to close the public schools on account of the widespread and fatal epidemic of scarlet fever, that gentleman has again urgently repeated the suggestion, supported by the decided opinions of Drs. Macdonald and Douglas. He shows that many workmen have been thrown out of employment in consequence of the illness of their children, and that the disease continues to spread. Ultimately it was agreed to close the schools, with the exception of a middle-class institution, and this halting measure is said to have caused much dissatisfaction in the district.

Five new wards are at present being added to the Royal Infirmary at Stirling, and besides this, further accommodation will be provided for the convenience of the out-door patients and nurses. The cost is estimated at about £1500.

Mr. Hunter, of Forfar, sustained a rather serious accident on Saturday last. His horse shied and reared in such a manner that he was thrown backwards from the gig, falling with much violence upon the pavement.

### PARIS.

(From our Special Correspondent.)

THE epidemic of typhoid fever now raging in Paris is assuming such proportion that those who have no serious motive for visiting the city at the present time will do far better to stay away. During the week ending October 2nd, there were 536 admissions for typhoid into the Paris hospitals. In the six days ending October 8th, the number was nearly doubled, being 1001; and it is probably within the mark to estimate that there are now 3000 cases in the hospitals alone, to say nothing of those that are treated by private practitioners. At the Lariboisière, which is within a stone's throw of the Northern Railway Station, there were between four and five hundred patients last Saturday, and the other hospitals are all crowded with similar cases. A few weeks since, the disease, although extending, remained of a mild type, but it is now becoming far more fatal, and as the past week has shown a larger number of invasions than any previous one, it is to be feared that the death-rate will become even greater than at present. The causes of the present epidemic may to a certain extent be meteorological and cosmic, and consequently beyond human reach or prevision; but there are many conditions which make typhoid endemic, with a regular weekly death-rate of 30, which can and ought to be remedied.

Every one who has been in Paris must be familiar with the bad smells that prevail even in the best parts of the town. These, to a great extent, arise from the cesspools beneath the houses, and make their way up the imperfectly trapped pipes. A flat or apartment in a fashionable quarter, consisting of a drawing-room, dining-room, and from three to seven bedrooms, will vary in rent from £200 to £500 a year, according to circumstances; yet with such a rent the water-closet accommodation is generally inferior to that of an English workman's cottage. In the apartment occupied by your correspondent every drop of water must be placed by hand in a little reservoir, which is anything but sufficient for flushing the pipes. Whenever the weather is stormy the fact becomes painfully obvious by the disagreeable odour that pervades the house. As an average cesspool receives the sewage of from twelve to twenty or more families, supplying them in return with sewer-gas, the wonder is not that there is so much typhoid, but that any susceptible person can escape when there is a case in his house.

### ROYAL COLLEGE OF SURGEONS.

AT a quarterly meeting of the Council of the Royal College of Surgeons, held on Thursday last, Mr. Thomas Bryant was elected a member of the Court of Examiners in the place of Mr. Birkett, who retires; and Mr. Cooper Forster was elected Mr. Birkett's successor on the Board of Examiners in Dental Surgery. Sir James Paget was nominated the Bradshawe Lecturer. Though the date has not been fixed, it is thought that the lecture will be delivered before the close of the present year.

## THE NEW ENTRIES.

THE following are the numbers of new students at the Medical Schools from which returns have been received:—

	Full Course.	Occasional.	Total.
St. Bartholomew's ...	110	51*	161
University College ...	89†	55‡	144
London ...	87	40	127
Guy's ...	81	15	96
St. Thomas's ...	62	31	93
Charing-cross ...	41	19	60
St. George's ...	42	6	48
Middlesex ...	37	6	43
King's College ...	35	—	35
St. Mary's ...	26	6	32
Westminster ...	24	1	25
Owens College, Manch. ...	58	18 (- 12‡)	76
Bristol ...	29	—	29

\* Thirty-six of these are students for London University.

† "Mostly full."

‡ Prelim. Scient.

## Obituary.

## THOMAS PALMER, M.D. LOND.

DR. PALMER, who died on the 8th inst., was born in 1819, and was the son of the Rev. H. Palmer, of Vjcars Hill, Tipperary. On completing his professional studies in Dublin he came to London. For some time he was house-surgeon to the Western General Dispensary. On quitting this post he practised successfully for many years in Southwick-street and Radnor-place, Hyde Park. Whilst engaged in public and private practice he so studied that he graduated at the London University "with honours." He was occasionally an original contributor to this journal. He was of a very retiring disposition; otherwise, by his abilities and his persevering industry, he might have gained a distinguished career. After some years spent in laborious practice his health gave way, and he was obliged to retire. In the early spring, in spite of a severe cold, he went, as was his custom, to Switzerland, where he was seized with pleuro-pneumonia. He partially recovered, but continuing his travels, he had a relapse, and after a painful struggle to return home from Berne, he reached the residence of his friend Dr. Fussell, at Brighton, moribund, and died in three days.

## JOHN HAXWORTH, M.R.C.S., L.S.A.

THE subject of this notice was a well-known man in Sheffield and father of the medical profession in that town. He commenced the study of his profession under Mr. Hounsfield in 1814, and after attending the infirmary there completed his studies at Guy's and St. Thomas's. After qualifying he became partner with his former master, and continued to reside in the same house until his retirement, a few months ago, after sixty years' work. Retaining the old style of dress, his familiar form was easily recognised. His principal appointment was that of honorary surgeon to the Bluecoat Charity School. Ever in the van to do a kindly action, he still had the most scrupulous regard for professional honour and integrity, from which no temptation could make him swerve. A man of active habits, he maintained his mental and bodily vigour unimpaired to the last. A severe cold caught in London a fortnight before developed an attack of broncho-pneumonia, which proved fatal on July 5th. at the age of eighty-four years. Rich and poor alike joined in paying a last tribute as his remains were laid to their rest.

MIDLAND MEDICAL SOCIETY. — At the annual meeting on Oct. 11th the following gentlemen were elected office-bearers to the Society:—President: E. Malins, M.D. Treasurer: J. Harmar. Secretaries: H. Eales and T. F. Chavasse. Members of Council: Thos. Savage, M.D., H. R. Ker, Beunett May, B.S., A. H. Carter, M.D. Five guineas each were voted to the Medical Institute and to the Medical Benevolent Society of Birmingham.

## Medical News.

UNIVERSITY OF DURHAM. — The following candidates have passed the First Examination for the Degree of Bachelor in Medicine:—

Archer, Edmund Lewis, M.R.C.S., St. Bartholomew's Hospital.  
Bate, John Fredk., University College Hospital.  
Blight, William Lyne.  
Dixon, Henry W., Newcastle-on-Tyne.  
Harper, John Maurice, London Hospital.  
Hartley, Isaac, Newcastle-on-Tyne.  
Jaques, William, Newcastle-on-Tyne.  
Lazenby, James, Newcastle-on-Tyne.  
Mosse, Herbert, Charing-cross Hospital.  
Newbolt, George P., St. Bartholomew's Hospital.  
Ople, Edward Augustus.  
Robinson, Louis, St. Bartholomew's Hospital.  
Robson, James Matthew, B.A., Newcastle-on-Tyne.  
Thistle, Fredk. T., L.R.C.P., St. Bartholomew's Hospital.  
Woolmer, Shirley Lawrence, University College Hospital.

The following candidate passed in Honours (Second Class):—  
Roberts, James R., Middlesex Hospital.

Ten candidates failed in the examination as a whole. Two failed in Chemistry only, and one in Botany only.

APOTHECARIES' HALL. — The following gentlemen passed the examination in the Science and Practice of Medicine, and received certificates to practise, on Oct. 12th:—

Iliewicz, Henry Frederick, Marquess-road, Canonbury.  
Leftwich, Charles Harcourt, Newcross.  
Manley, John Herbert Hawkins, West Bromwich.  
Tripp, Chas. Llewellyn Howard, Royal Free Hospital.

MR. HENRY DE MÉRIC has resigned his appointment as surgeon to the French Hospital and Dispensary.

A NEW Cottage Hospital has just been opened at Aylburton, Gloucestershire.

THE Treasurer of Addenbrooke's Hospital, Cambridge, has received the sum of £147 as the first instalment from the proceeds of this year's Hospital Saturday collection.

CANTON is soon to be supplied with pure water by a native waterworks company. The capital, which is subscribed by Chinese entirely, amounts to £60,000.

THE Metropolitan Board of Works are about to try to carry out four schemes under the Artisans' Dwellings Acts, with the improved powers given to them under the new Act of Parliament.

THE Princess of Wales paid a visit on Saturday last to the London and Ascot Convalescent Home at Ascot. Her Royal Highness passed through the wards, and expressed her interest in the patients and her pleasure in the arrangements of the institution.

NORTH-WEST LONDON HOSPITAL. — The Lady Mayoress, accompanied by the Lord Mayor and Sheriffs, will lay the foundation stone of the new wing of this hospital in the Kentish-town-road on Wednesday, the 25th inst., at three o'clock.

THE WESTMINSTER HOSPITAL MEDICAL SCHOOL. — The Fence Entrance Scholarship of £40 per annum for two years has been awarded to Mr. E. O. Cox, and the Entrance Scholarship of £20 for two years to Mr. H. Brackenbury and Mr. H. S. Cooper (equal).

ROYAL COLLEGE OF SURGEONS, EDINBURGH. — At the annual meeting of the College on the 18th inst., the following office-bearers were elected for the ensuing year:—  
President: Mr. William Turner. Secretary and Treasurer: Mr. Joseph Bell. Librarian: Dr. A. Dickson. President's Council: Drs. Henry D. Littlejohn, Patrick Heron Watson, David Wilson, Mr. Francis Brodie Imlach, Drs. John Smith and Douglas Argyll Robertson. *Ex officio*, Mr. Joseph Bell, Examiners: Drs. J. D. Gillespie, H. D. Littlejohn, Patrick H. Watson, David Wilson, John Smith, Mr. Joseph Bell, Dr. J. Duncan, R. J. Blair Cunynghame, Alex. G. Miller, and P. H. MacLaren; Mr. Johnston Symington and Dr. R. Macneir. Dental Examiners: Dr. Patrick H. Watson, Mr. Francis B. Imlach, Drs. H. D. Littlejohn and John Smith, Messrs. Andrew Wilson and George W. Watson. Assessors to Examiners: Mr. William Brown, Dr. J. S. Combe, Mr. Benjamin Bell, and Mr. W. Walker. Conservator of Museum: Dr. R. J. Blair Cunynghame. Clerk: Mr. J. Robertson. Officer: Mr. Colin Mackenzie. Assistant to Conservator: Mr. George Reid.

**MEDICAL MAGISTRATE**—His Grace the Duke of Devonshire, the Lord Lieutenant, has placed William Webb, M.D., F.R.C.S., of Wirksworth, on the Commission of the Peace for the County of Derby. Dr. Webb qualified as a magistrate at the quarter sessions held at Derby on the 17th instant.

**UNIVERSITY COLLEGE, LONDON.**—Andrews Entrance Prizes of £20 have been awarded for Science to T. Varley and J. H. Hooker, and for English and other languages to T. M. Neatby. The Medical Entrance Exhibition of £100 has been awarded to H. P. Dean, that of £60 to W. P. May, and that of £40 to C. W. Jecks. L. A. Legros has gained the Gilchrist Entrance Scholarship in Engineering of £35 per annum for two years.

A CASE in which the death of an infant was attributed by the medical witness to a "soothing syrup" was under investigation by Dr. Diplock on Monday. The jury, in returning a verdict of "Death by misadventure," added a rider to the effect that some restriction should be placed on the sale of patent medicines which could be used as poisons. It is unfortunate that the official interests of the Chancellor of the Exchequer and the health interests of the public are in conflict in this matter.

**ANOTHER DEATH WHILE UNDER CHLOROFORM.**—Another fatal case of chloroform administration is to be added to the rapidly growing list. The lamentable event occurred at the Royal Berks Hospital on the 10th inst., the patient being an apparently healthy herdsman, who cut his finger whilst sharpening a scythe. Disease supervening in the joint, it was proposed to remove the digit, for which purpose, at the patient's request, chloroform was administered. Before the operation was commenced, however, the man ceased to breathe. A necropsy revealed the existence of cardiac disease, in the opinion of the house-surgeon, the result of an old attack of pleurisy.

**GLASGOW SOUTHERN MEDICAL SOCIETY.**—At a meeting of the Glasgow Southern Medical Society held in Fleming's Temperance Hotel, 11, Bridge-street, on Thursday evening, the 12th inst., the following gentlemen were elected office-bearers for the ensuing session, 1882-83:—President: Dr. James Barras. Vice-President: Dr. Robert Park. Treasurer: Dr. Edward McMillan. Secretary: Dr. N. T. Smith. Editorial Secretary: Dr. Robert Pollok. Seal Keeper: Dr. R. W. Forrest. Court Medical: Dr. Carmichael (convener), Dr. Macfarlan, Dr. John White, Dr. John Dougall, and Dr. James Morton. Council: Dr. W. Carr, Dr. T. F. Gilmour, and Dr. Alex. Napier.

**SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.**—A quarterly court of the directors of this Society was held on October 11th, in the rooms of the Royal Medical and Chirurgical Society. The chair was taken by the President, Sir George Burrows, Bart. Two new members were elected. The death of one widow was reported, and two orphans had ceased to be eligible for further grants. Applications for grants were received from sixty-one widows, five orphans, and three orphans on the Copeland Fund, and it was resolved that a sum of £1259 10s. be recommended for distribution at the next quarterly meeting. The quarterly expenses amounted to £34 17s. The state of the funds permitting, it was resolved, on the motion of the acting treasurer, to make a Christmas present to the widows and orphans in December next. The report of the committee on the revision of the by-laws was considered, and it was resolved that many important alterations should be submitted for approval at a general meeting of the Society.

## Medical Appointments.

*Intimations for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning at the latest.*

**ARMSTRONG, WILLIAM, M.R.C.S.**, has been appointed Deputy Medical Superintendent of the Yarra Bend Lunatic Asylum, South Australia.

**AYRES, ALFRED R. ASTON, L.R.C.P. Ed., M.R.C.S.**, has been appointed Medical Officer for the Preston District of the Brighton, Hove, and Preston Provident Dispensary.

**BARLING, HARRY GILBERT, M.B. Lond., M.R.C.S.**, has been appointed Resident Surgical Officer to the General Hospital, Birmingham.

**BELL, JOSEPH C., F.C.S.**, has been appointed Public Analyst for the Borough of Birkenhead, vice Vacher, resigned.

**BENSON, A., F.R.C.S. I.**, has been appointed one of the Surgeons of the Dublin Throat and Ear Hospital, vice Windle, resigned.

**BUCHAN, WILLIAM AUGUSTUS, M.B. Edin.**, has been appointed House-Surgeon to the Clinical Hospital, Manchester.

**BUCHANAN, PETER, M.B., C.M. Glas. Univ.**, has been appointed Certifying Surgeon of Factories in the Coleford District, Gloucester.

**CARLESS, G. NICOLLS, M.B.**, has been appointed Medical Officer to Her Majesty's Prison, Devonize, vice Edward Clapham, M.D., resigned.

**HALL, B., M.B. Lond., M.R.C.S.**, has been appointed Assistant Medical Officer at Earlswood Asylum, vice Dr. Jones, appointed an Assistant Medical Officer at Colney Hatch.

**JAMES, HENRY, L.R.C.P. Ed., M.R.C.S.**, has been appointed Visiting Physician to the Austin Hospital for Incurables, Australia.

**LUCAS, HERBERT, M.R.C.S., L.S.A. Lond.**, has been reappointed Medical Officer of Health for the Godmanchester Urban Sanitary District.

**NEWCOMBE, FRANK, M.R.C.S., L.S.A. Lond.**, has been appointed Medical Officer for the Clifton District of the Newark Union.

**SCOTT, CHARLES C., M.B., C.M. Edin.**, has been appointed House-Surgeon to the Ayr New Hospital, and Surgeon to the Dispensary.

**SPENCE, WILLIAM JAMES, L.R.C.P. Ed., L.R.C.S. Ed.**, has been appointed Resident Physician to the Bradford Infirmary and Dispensary, vice Foster, resigned.

**STRAVENSON, W. E., M.B. Cantab., M.R.C.S., S.Sc. Cert. Camb.**, has been appointed Electrician to St. Bartholomew's Hospital, London.

**THOMSON, ALEX. GUTHRIE, L.R.C.P. Ed., L.F.P.S. Glas.**, has been appointed Medical Officer to the Horsmonden District of the Tonbridge Union.

**WATKINS, WILLIAM LONGWORTH, L.K.Q.C.P.I., L.R.C.S.I.**, has been appointed Medical Superintendent of the Guntary Lunatic Asylum, South Australia.

## Births, Marriages, and Deaths.

### BIRTHS.

**CAPON.**—On the 6th inst., at Edgware-road, W., the wife of Herbert J. Capon, M.D., L.R.C.P. Lond., &c., of a daughter.

**KILNER.**—On the 11th inst., at Bury St. Edmund's, the wife of Charles Scott Kilner, M.B., of a daughter.

**POTTS.**—On the 12th inst., at Sunnyside, Leatherhead, Surrey, the wife of Laurence Potts, M.R.C.S. &c., of a son.

**RENDALL.**—On the 10th inst., at Malden Newton, the wife of William Rendall, M.R.C.S., of a daughter.

**TURNBULL.**—On the 9th inst., at Kelso, N.B., the wife of G. H. Turnbull, M.D., of a son.

### MARRIAGES.

**ATKINS-INNES.**—On the 11th inst., at St. Mary's Church, Chigwell, Essex, Thomas Gelston Atkins, B.A., M.D., son of William Atkins, Esq., of Cork, to Mary Eliza (Nenone), eldest daughter of the Rev. Canon Innes, M.A., Rector of London, Ontario, Canada.

**DEVIS.**—**CATELL.**—On the 4th August, at Townsville, Queensland, Charles James Devis, M.R.C.S.E., L.S.A. Lond., formerly of Birmingham, eldest son of C. W. Devis, B.A. Cantab., to Alice, youngest daughter of William Cattell, Esq., of Leamington.

**HEATH.**—**BROWN.**—On the 10th inst., at St. Paul's, Newcastle, W. Lenton Heath, M.B., B.S., F.R.C.S., of Gloucester-road, South Kensington, to Bertha, youngest daughter of Arthur Brown, Esq., of High Park-road, Newcastle-on-Tyne.

**HILTON.**—**WOOD.**—On the 10th inst., at St. Augustine's, Northbourne, Kent, Thomas Denne Hilton, M.B., of Upper Deal, son of the late Rev. John Hilton, of Sarre Court, Isle of Thanet, to Emily Elizabeth, eldest daughter of the Rev. Thomas Wood, Rector of Northbourne.

**LAURENCE.**—**CAMPBELL.**—On the 17th inst., at St. Mark's, Regent's-park, by the Rev. F. Earle, Rector of Tanfield, Yorkshire, the Rev. Richard Laurence, Rector of Chigwell-row, Essex, to Frances, widow of W. Campbell, M.D., F.R.C.S. Eng., late of Bangkok, Siam.

**MACQUEEN.**—**GERARD.**—On the 10th inst., at Palmerston-place, Edinburgh, Daniel Macqueen, M.D., Deputy Surgeon-General, Army Medical Department, to Keturah Jane, daughter of the late James Gerard, of Midstrath, Aberdeenshire.

### DEATHS.

**COOPER.**—On the 13th inst., at Shelburne-road, Holloway, Charles Cooper, L.S.A. Lond., aged 70.

**GREENFIELD.**—On the 18th inst., Evelyn Mary, second daughter of W. S. Greenfield, M.D., F.R.C.P., of Edinburgh, aged 2½ years.

**HOLMES.**—On the 13th inst., at Tudor House, Lyme Regis, Thomas James Holmes, M.D., son of the late Robert Holmes, of Holmesdale Cottage, Lyme Regis, aged 65.

**JOHNSTON.**—On the 17th inst., at Southsea, James Wingate Johnston, M.D., Inspector-General, R.N., Honorary Surgeon to the Queen.

**PALMER.**—On the 8th inst., at his friend's residence, Clifton-terrace, Brighton, after a long illness, and three days subsequent to his return from Switzerland, Thomas Palmer, M.D. Lond., formerly of Radnor-place, Hyde-park, son of the late Rev. H. Palmer, of Vicar-hill, Cahir, Ireland, aged 63.

**RHODES.**—On the 17th inst., at Weymouth, Charles Rhodes, M.D., aged 41.

**N.B.**—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

## METEOROLOGICAL READINGS.

## Medical Diary for the ensuing Week.

## Monday, Oct. 23.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10½ A.M. each day, and at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M. each day, and at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPEDIC HOSPITAL.—Operations, 2 P.M.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.; on Tuesday, 9 A.M.

MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Rycliffe Crocker, "On a Skullcap from a Case of Congenital Syphilis," which was shown last session.—Mr. Francis Mason (the President), "On a Case of Gastronomy (with specimen)."—Mr. Thomas Bryant, "On Inflammation and Ulceration of the Tongue."

## Tuesday, Oct. 24.

GUY'S HOSPITAL.—Operations, 1½ P.M., and on Friday at the same hour.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 3 P.M.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Mr. Barwell, "On Dislocation of the Foot, with Version and Torsion of the Astragalus."—Dr. P. Warner, "On Ophthalmographia Externa, complicating a case of Graves's Disease."

## Wednesday, Oct. 25.

NATIONAL ORTHOPEDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.

ST. THOMAS'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.

ST. MARY'S HOSPITAL.—Operations, 1½ P.M.

LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

GREAT NORTHERN HOSPITAL.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2½ P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at the same hour.—Skin Department: 1.45 P.M., and on Saturday at 9.15 A.M.

HUNTERIAN SOCIETY.—8 P.M. Dr. Charlewood Turner will show a Heart of Two Chambers.—Dr. Herman, "On the Clinical Classifications of Backward Displacements of the Uterus."

## Thursday, Oct. 26.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—1½ P.M. Surgical Consultations.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and on Friday at the same hour.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2½ P.M.

## Friday, Oct. 27.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1½ P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 2 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.

QUEKETT MICROSCOPICAL CLUB.—8 P.M. Mr. T. W. Morris, "On the Fibro-vascular Bundles in Ferns, and their value in Determining Generic Affinities."

CLINICAL SOCIETY OF LONDON.—Mr. Walsham, "On a Case of Gun-shot Injury of the Lower Jaw."—Dr. Mahomed and Mr. Pepper, "On a Case of Ligation of the Common Carotid Artery for Hemorrhage from the Throat, due to Ulceration after Scarlet Fever."—Dr. Crocker, "On a Case of Hematuria from Bilharzia Hematobia (specimens of the parasite will be shown)."—Mr. Golding Bird, "On a Case of Removal of the Uterus for Fibroid Disease."

## Saturday, Oct. 28.

KING'S COLLEGE HOSPITAL.—Operations, 1 P.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

## Notes, Short Comments, and Answers to Correspondents.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*All communications relating to the editorial business of the journal must be addressed "To the Editor."*

*Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.*

*Lectures, original articles, and reports should be written on one side only of the paper.*

*We cannot prescribe, or recommend practitioners.*

*Local papers containing reports or news-paragraphs should be marked.*

*Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."*

## "THE DANGERS OF TRAMWAY TRAVELLING."

UNDER this heading a contemporary calls attention to the defective ventilation of tramway cars. Doubtless there are in some localities—and those which would seem most likely to be well cared for—cars so constructed that foul air may be detained in them; but the worst of public vehicles of this class are incomparably better than the average of omnibuses. We have protested on several occasions against the neglect of proper ventilation in regard to the case of omnibuses, and the facts have not been overstated. Under the best of circumstances an omnibus must be a perambulating disseminator of disease. This is a source of mischief which deserves and requires to be taken into serious consideration, and upon the perils of which the public need to be put on their guard.

Mr. Robert Jones.—The paper is marked for early insertion.

## THE INDIAN MEDICAL SERVICE: A WARNING.

To the Editor of THE LANCET.

SIR,—Another "job" is, I understand, about to be perpetrated in India at the expense of the medical service. Sir Alexander Christison retires from the surgeon-generalship, North-West Provinces and Oudh, in October next, and will be succeeded by Dr. Walker, the Inspector-General of Prisons. Dr. Walker's appointment is to be given to a civilian. For your readers to appreciate the injustice of such an appointment it will be necessary for me to explain the connexion of the service with the gaols. Up to within the last twenty or thirty years the administrative and executive duties of gaols were entirely in the hands of civilians. In consequence of the failure of the gaol system under civilian officers, the department was handed over to the medical service, with a doctor as Inspector-general, and civil surgeons as superintendents of gaols in their respective districts. Large central prisons, capable of containing two or three thousand prisoners, were erected, and placed entirely under the charge of medical officers, who showed a special aptitude for gaol work. It is now, and has been for years past, a well acknowledged fact that the gaols in the North-West Provinces are a pattern to those in the rest of India. The efficiency of this department is now about to be recklessly sacrificed and a large body of officers made discontented simply to provide a good appointment for civilians, and thus remove to some extent the block in their promotion. Disaster must follow by placing a civilian at the head of a purely medical department. The medical superintendents will never work with advantage or harmoniously under a civilian chief, and friction, ending in hopeless confusion, must be the result.—I remain, Sir, yours, &c.,

Oct. 1882.

GAOL OFFICER.

H. M. L. may refer to Dr. MacEwen's book on the subject, published by J. and A. Churchill, or to his lecture, which appeared in THE LANCET on Sept. 13th, 1880.

Mr. N. D. Cohen is referred to a general notice at the head of this column.

J. D.—The paper will be inserted as early as possible.

## "THE 'EIRA' ARCTIC EXPEDITION."

To the Editor of THE LANCET.

SIR,—As I see by your impressions of Aug. 26th and Sept. 2nd that the non-occurrence of scurvy in the late Eira Expedition is again brought prominently before the public, I would beg to call your attention to my article on this subject published in your impression of January 17th, 1883, p. 61. I also published an article in the Army and Navy Gazette of June 9th, 1877, which will be found of much interest.

I am, Sir, yours faithfully,

W. S. OLIVER, Brigade Surgeon.

Spring-garden-road, Halifax, N.S., Oct. 2nd, 1882.

## SEATS FOR SHOPWOMEN.

A DEPUTATION will shortly wait on the owners of the principal drapery establishments in Belfast for the purpose of inducing them to provide seats for their female assistants. A very influential ladies' committee has taken up the matter, and a circular has been issued in which they ask the concession with confidence, believing that any little inconvenience attending the change of practice will be amply made up by increased diligence on the part of the females employed. We have little doubt but that the leading establishments in Belfast will comply with the wishes of the deputation.

*Ethnologist.*—Dr. Crowther, F.R.C.S., of Hobart Town, was severely handled for endeavouring to secure the skeleton of King Billy, a celebrated aborigine, for the museum of the Royal College of Surgeons, and had to restore it; soon after which the skull was missing, and now that of Guiteau has been taken from the Washington Museum. The skulls of Eugene Aram, Jonathan Wilde, and John Thurtell are in the museum of the Royal College of Surgeons.

*Dr. Evans.*—Our correspondent should submit his suggestions to the head of his department. They are chiefly matters of detail, which could be more advantageously considered in that manner, and with more chance of being adopted, than if discussed in our columns.

*Mr. T. Smart.*—Certainly not. He should have consulted another surgeon.

## "TESTIS IN PERINEO."

To the Editor of THE LANCET.

SIR,—Allow me to add another case to the list of this malformation. The deformity was noticed a few days after birth. The child is now about five months old, and otherwise very well developed. The left half of the scrotum is perfectly normal, and contains a well-formed testis. The right half is well formed, contains "dartoid tissue," but is minus its usual occupant; it is perfectly separated from its fellow by the septum. The "missing tenant" has taken up its quarters on the right half of the perineum, partially under cover of the ramus of the ischium, and is covered by normal integument. The testis is smaller than its fellow, is freely movable up as far as the "external ring," but cannot be replaced in the scrotal pouch. The "cremaster reflex" is fairly developed on both sides, especially when the parts are relaxed by warmth. The parents are anxious to have "something" done, either in the way of "removal" or by "transplanting" to its normal scrotal pouch. Has any attempt ever been made to transplant the testis under the above conditions? Would the division of the false "septum" subcutaneously with a tenotomy be of any use? I may add that there is no hernia.

I remain, Sir, yours faithfully,

T. HENDERSON POUNDS, M.R.C.S.

Snodland, Rochester, Oct. 5th, 1882.

To the Editor of THE LANCET.

SIR,—The above subject seems to interest several of your correspondents just now. No one, however, has pointed out the fact that, in the edition of the Medical Digest just published, a series of papers, culled both from THE LANCET and other journals, giving full details of the best operative procedures may be consulted in section 1219:4. Allow me to bear my testimony to the daily value of Dr. Neale's work to every practitioner of whatever grade or attainments.

I am, Sir, yours faithfully,

Birchington-road, Kilburn, N.W.,  
Sept. 30th, 1882.

D. TEMPLETON HOSKYN.

*L.R.C.P. Ed.*—Our strictures have reference not to the examiners, but to the examinations and the system by which one body accepts the examinations of another.

*Theta (Dundee)* has not enclosed his card.

## "THE EFFECT OF LIGHT IN AIDING SNEEZING."

To the Editor of THE LANCET.

SIR,—Sneezing is a reflex act, the afferent fibres being the nasal branches of the fifth nerve; but Foster states that in those persons in whom a bright light causes sneezing the optic nerve appears to become the afferent nerve in the reflex chain. Why this should be so in some persons and not in others must, I suppose in our ignorance, be said to be due to idiosyncrasy. From Foster's words one would gather that any bright light would thus produce sneezing, but to judge from the case of your correspondent, "A Layman," and of my own, sunshine alone is capable of producing this result. Looking up to a bright sun always produces sneezing in my case, whether I have previously felt a desire to sneeze or not; but in the previous case the resulting sneeze is more vigorous.

Oct. 7th, 1882.

I am, Sir, yours, &c.,

R. P.

To the Editor of THE LANCET.

SIR,—I beg to submit the following reply to "Layman's" alleged "effect of light in aiding sneezing." May the impression referred to by him not be attributed to the fact that in the act of looking upwards at the sky or clouds a larger surface of mucous membrane of the nostrils is exposed to the waves of air, with consequent increased irritation, than when in a normal position? Has "Layman" ever tried the effect at sunrise or sunset? If with the result he mentions, it might then be attributed to the light.—I am, Sir, yours, &c.,

Hull Dispensary, Yorks, Oct. 11th, 1882.

P. W. G. CANNING.

## PAY HOSPITALS.

THE last issued number of the *Philanthropist* publishes a table of pay hospitals and departments. The table includes a list of sixteen institutions with this feature in their constitution, and adds in separate columns the address, the number of beds for paying patients, the average number of such patients in the year, the year when such beds were first provided, the charges per week, and information as to whether the charges include medical attendance and all necessaries. The list is not quite complete, but may be useful for reference.

*J. P.*—It was seriously debated at the Mansion House in 1572, before William Allen, the Lord Mayor, the Bishop of London, the Master of the Rolls, and other learned persons, whether a surgeon could lawfully prescribe internal remedies, when it was decided he could not—not even in "morbo gallico," and a surgeon was afterwards mulcted for so prescribing.

## "A DISAGREEABLE DUTY."

To the Editor of THE LANCET.

SIR,—The grounds on which I made my statement referring to the non-appearance of Mr. Wise's name in the Medical Register and Directory were these: a careful examination of both these books and a visit to the registration office, where I was told there was no such person on their list as Alfred Wise, M.D. There was an Alfred Thomas Tucker Wise, late of Sutherland-gardens, who was travelling in Switzerland at the present time, and entered in the Directory as being abroad. I have since learned that this gentleman formerly lived in Church-street, Bethnal-green, so conclude that Dr. Alfred Wise now writing to THE LANCET and Dr. Alfred Thomas Tucker Wise are one and the same person. This being so, I am only too happy to retract my statement, and apologise for the error unwittingly committed.

It is greatly to be regretted that Dr. Wise, in making a complaint in THE LANCET, should have neglected to sign both his name and qualifications in full.

I still maintain that Dr. Wise had no discourtesy shown him, and the facts of my last letter referring to what passed in the hospital remain unaltered and unanswered.—I am, Sir, yours, &c.,

RICHARD HINGSTON, M.R.C.S., &c.

London Hospital, E., Oct. 17th, 1882.

*J. S. O.*—The clerk is, unfortunately, right; neither etiquette nor equity is "in the bond" which blinds medical men in the service of "guardians of the rates." The medical officer has no professional "rights" in his incumbency, and he is not master of his work or of those appointed to act nominally under him as "assistants."

*Mr. C. F. Jesusbury.*—The documents are not now in our possession.

## "CARFERAL."

To the Editor of THE LANCET.

SIR,—In answer to "Æsculapius's" inquiry, carferal is, as its enigmatical name denotes, a mixture of carbon, ferrum, and aluminium, the latter being the principal ingredient, with about two per cent. of iron, and a very small proportion of carbon. It can only be used in a granular form, and for this reason is, in my opinion, inferior to silicated carbon. Its cost is from 28 to 23 per ton, and it can be obtained from the Carferal Company, whose offices I believe are in Queen Victoria-street. Silicated carbon in slabs is far preferable as a medium for filtering water.

I am, Sir, yours faithfully,

Oct. 11th, 1882.

F.R.C.S.

To the Editor of THE LANCET.

SIR,—In reply to "Æsculapius," car-fer-al is a mixture of carbon, iron, and aluminium. Filters containing this material are manufactured by Messrs. Murray and Co., Caledonian Pottery, Rutherglen, Glasgow, who will doubtless give any information required.

I am, Sir, yours truly,

Liverpool, Oct. 7th, 1882.

ALFRED H. MASON.

*Idiot.*—We are not aware of the existence of an institution specially appropriated to the class of sufferers mentioned, save that at Earlswood.

*Iconoclast.*—We are sure that neither of the corporations mentioned will take the trouble to prevent the use of the title named.

## A TACK IN THE EAR.

To the Editor of THE LANCET.

SIR,—I presume the discovery of a carpet tack in the external auditory meatus is not a very usual occurrence, and I therefore send a short note of the case.

A lady consulted me a few days ago for deafness and occasional throbbing in the right ear, and on examination with the ear-speculum I found a black mass on the bottom of the meatus. Being firmly imbedded in a mass of clotted blood, wax, and cotton-wool, it resisted all attempts at removal by the use of a large syringe and hot water; but by the aid of a small artery forceps and a short hook set in a handle, I succeeded in extracting a carpet tack, head foremost. As the mass completely plugged up the meatus (in which it had been for years), it was very difficult to extract. She now hears perfectly.

I am, Sir, your obedient servant,

Spring-grove, Upper Norwood, S.E.,  
Oct. 10th, 1882.

EDWARD HAUGHTON, M.D.

## TESTIMONIALS BY HOUSE-SURGEONS.

**THE Exeter and Plymouth Gazette** of Oct. 6th contains an absurd puff of what is called the Imperial Ottoman Healer, as a remedy for everything, from burns to bronchitis. But the most absurd part of it is a testimonial to the virtues of this secret nostrum by the house-surgeon of the Salop Infirmary. Surely it is not among the duties of house-surgeons to give testimonials of this kind.

**Mr. G. H. Smith** (Southsea).—The account of Taylor's freezing microtome, given in *THE LANCET* for Oct. 7th, seems to us quite clear, and we would recommend our correspondent if he wishes to obtain further particulars, to write to Dr. Thomas Taylor, of Washington, U.S., who, we do not doubt, will furnish him with the particulars he requires, or, if need be, supply him with one of his microtomes.

## "BELLADONNA POISONING."

To the Editor of *THE LANCET*.

SIR,—Referring to Dr. Miller's case of belladonna poisoning, mentioned in your issue of the 7th inst., I can give my own personal experience of an overdose of that drug.

A short time ago, while suffering from tic, I proposed to give myself a hypodermic injection of morphia. Going into the surgery at night, I took down a bottle and gave myself an injection. Almost immediately I was seized with the most alarming symptoms, which I did not recognise as those following the administration of morphia. On giving it a little thought, I suddenly remembered that I had taken down the wrong bottle, and found I had injected a solution of atropine, the dose given being 1-60th of a grain. My chief symptoms were a greatly accelerated pulse (130), intense thirst, and dryness of tongue and throat, widely dilated pupils, and a condition which I felt narrowly approached delirium. I immediately injected half a grain of morphia, and, to my great mental relief, the symptoms gradually disappeared, and I went about the next morning as usual.—I beg to remain, Sir, yours truly,  
Leeds, Oct. 10th, 1882.

MEDICAL.

**Incredulous.**—The circumstance as related cannot have occurred. Possibly the lecturer mistook the gin-bottle in the woman's hand for the mamma. The evenings are drawing in.

M.R.C.P. Edin. might apply to Tribner and Co., Paternoster-row.

## ENGLISH UNION HOSPITALS.

To the Editor of *THE LANCET*.

SIR,—I would be greatly obliged if some of your English Poor-law readers would state what is the practice of their English Local Government Board in the case of such a medical appliance as a weighing machine. Some time ago I ordered one for hospital, when, to my astonishment, the Irish Local Government Board refused to allow for it as a medical appliance; thereupon the hospital authorities requested them to reconsider the matter on these grounds:—1. That no well-ordered hospital is now without such in connexion with the treatment of the sick. 2. That it is exclusively used for such. 3. That it is necessary. 4. That the mere fact that similar machines are employed for other purposes cannot therefore deprive this one of the character of a medical appliance. The result was their continued refusal.

I am, Sir, yours, &c.,

THOMAS LAFFAN.

Cashel, Oct. 3rd, 1882.

## COMPRESSED AIR BATHS.

To the Editor of *THE LANCET*.

SIR,—A patient of mine asked me for some information respecting the above. Can you or any of your readers tell me anything about them?

I am, Sir, yours faithfully,

M.D.

Oct. 12th, 1882.

\*. Compressed air baths are an old remedy, especially carried out at Reichenhall. They are apt to cause tinnitus aurium, pains in the ears, and headache. They slow the pulse; raise the arterial tension. They have been recommended in emphysema and whooping-cough. They are said to increase expectoration and excretion (Burdon-Sanderson in *Practitioner*, vol. I.). With only slightly compressed air the effects are mainly those of increased absorption of oxygen. Ducrocq, Waldenburg, Biedert, and Montard-Martin have written on this subject.—ED. L.

## PRUSSIC ACID IN ALBUMINURIA OF DIPHTHERIA AND SCARLATINA.

To the Editor of *THE LANCET*.

SIR,—I wish to draw attention to a remedy I have found useful in treating the albuminuria of diphtheria. In 1877 I gave to a patient under my care for diphtheria, which was attended by albuminuria and followed by extensive paralysis, full doses of the dilute hydrocyanic acid to allay vomiting. The next day I found the albumen had diminished 50 per cent., and in a few days all traces of it had disappeared. I have used the drug in several similar cases with uniformly good results since that time, and I have recently tried it in scarlatinal nephritis, in which disease it appears to be equally beneficial, diminishing the excretion of albumen and increasing the secretion of urine. I think it deserves a more extended trial than I can give it.

I am, Sir, yours, &c.,

Coleshill, Oct. 1882.

VERE G. WEBB, L.K.Q.C.P.I., &c.

## "HOLY WATER."

**THE Chemical Review** states that recent analysis of the water from the Holy Well at Mecca, which is so eagerly drunk by pilgrims, shows this water to be sewage, about ten times stronger than average London sewage.

**Suspicious.**—The *nom de plume* which our correspondent has chosen exactly expresses our views of the case. It is very shocking that a woman should be allowed to go on in labour till the os uteri was fully dilated, and then die without seeing a doctor. Our correspondent does not say if there has been an inquest. There certainly should have been one, and an examination of the contents of the stomach.

**F. M. S.**—Dr. Spencer Thomson has written a work on the subject.

A Victim should consult a physician on his case.

## "TREATMENT OF EPILEPSY."

To the Editor of *THE LANCET*.

SIR,—Your correspondent "Alpha's" question in the last number of *THE LANCET* gives me an opportunity of correcting a slight inaccuracy in my note of the 2nd inst.

The formulae given in the second paragraph of my letter are from Dr. Boyd's thesis, to which I referred to freshen my memory. My patient, however, did not take any valerian, nor is this an essential part of the treatment. Professor Ball's plan consists of the simultaneous administration of the bromides, with oxide of zinc and belladonna.

I mention this as a matter of fact, and in order to make known exactly what medicines I did use in this particular case, but I do not wish to convey the impression that the addition of the infusion of valerian is a matter of indifference. Although decidedly nasty, it is quite possible that it may enhance the efficacy of the other drugs; and even alone it is sometimes successful when other means have failed.

With this digression, I will now reply to "Alpha's" query. I prescribed one of the pills twice a day with breakfast, which on your side of the channel means lunch, and dinner, and I directed two tablespoonfuls of the bromide mixture (and it will be as well to mention that a French tablespoon is equal to fifteen grammes) to be taken the first thing in the morning, and the same quantity on going to bed.

I am, Sir, yours obediently,

OSCAR JENNINGS, M.D.

Boulevard Malesherbes, Paris, Oct. 17th, 1882.

## "A QUERY."

To the Editor of *THE LANCET*.

SIR,—The party, to whom Dr. F. Pratt alludes in his query in *THE LANCET* of Oct. 14th, has been in the habit of having morphia subcutaneously injected daily for years. In olden days, while under water treatment at Malvern, I used to hear of patients in whom, under the influence of packing, masses of old drugs that had deposited themselves in the system after imbibition exuded from the skin, especially in the vicinity of the liver. Dr. Charles Pratt, Dr. F. Pratt's brother, lately deceased, received this chronic victim of morphia coming into Apple-dore from a distance. He disliked the treatment, but did not exactly see his way to stop it. *Me judice*, Dr. F. Pratt has now had a very broad hint to drop morphia in this case.—I am, Sir, yours faithfully,  
October 16th, 1882.

G. H. J.

To the Editor of *THE LANCET*.

SIR,—Dr. Pratt's case seems to be somewhat analogous to one described in a paper read before the Medical and Surgical Society in June, 1845, and thought to be a kind of pityriasis nigra.—*Vide THE LANCET* for 1845, vol. II., page 46.—I am, Sir, yours, &c.,  
Penzance, Oct. 15th, 1882.

A. B. B.

## ACCIDENTAL POISONING.

To the Editor of *THE LANCET*.

SIR,—How often do we hear of accidental poisoning caused by persons mistaking poisonous lotions for medicines, and sometimes from ignorant nurses not able to read the labels. I recently purchased a small quantity of poison from a chemist in Germany, and was struck by the label affixed to the bottle. It was a death's head and crossbones, black on white ground, with the word "Gift," that is poison, printed underneath. The most ignorant or stupid could not mistake it even at night. I enclose a specimen, and would suggest its adoption by all apothecaries.

I am, Sir, yours, &c.,

Oct. 7th, 1882.

CHEYNE BRADY.

\*. It is clear we want still more precautions against accidental poisoning. The above suggestion seems a good one.—ED. L.

## "THE MINUTES OF EVIDENCE BEFORE THE ROYAL COMMISSION ON MEDICAL ACTS": THE PURCHASE OF HIGHER TITLES.

To the Editor of *THE LANCET*.

SIR,—The wording of Mr. Nelson Hardy's statement is rather unfair to the Edinburgh College of Physicians. A man must possess the knowledge necessary for the ordinary, and not only the modified, examination of the Apothecaries' Hall. The statement being made by Mr. Hardy is personally rather amusing, as, according to the Register, he took the M.R.C.S. Eng. in 1867, went north for his L.R.C.P. in 1868, and obtained the F.R.C.S. Ed. in 1872. I am sorry to be personal, but those who live in glass houses should not throw stones.

I am, Sir, yours obediently,

Oct. 1882.

M.R.C.S. Eng.

## THE GAFFNEY FUND.

THE following further sum has been received through Dr. A. P. Stewart:—

Mr. G. W. F. Bury, F.R.C.S. Eng., Barnet .. .. £2 2 0

W. M.—We cannot go quite so far as our correspondent. The right of the patient to go to another town and consult another practitioner cannot be questioned. The most that the practitioner could do was to communicate the fact to the regular attendant, and in taking this course we think he acted courteously.

## BRAIN PRESSURE IN ELEMENTARY SCHOOLS.

To the Editor of THE LANCET.

SIR,—You have been good enough on various occasions to direct the attention of your readers to the fact that an undue amount of pressure is sometimes brought to bear in preparing young people for the numerous examinations which are now the fashion of the day. Teachers are quite alive to the evils of the system; but anything which they may urge in mitigation of the injurious effects of over-pressure is set down as so much selfish argument in behalf of lightening their own work. The teachers who are engaged in the elementary schools of the United Kingdom are specially interested in the subject of the ill that arise from excessive brain pressure in the case of the young.

On behalf of the members of the National Union of Elementary Teachers, nearly 14,000 in number, I have to invoke your powerful assistance. The teachers are anxious to obtain the unbiased independent opinion of medical men as to the amount of illness among the children in attendance at elementary schools, which can be traced to overwork in the way of study, as compared with some ten or twenty years ago.

If your professional readers will favour us with their opinions on this important subject, either through the medium of your columns, or privately to myself, for the use of the National Union of Elementary Teachers, they will be doing a service to the cause of public health and of national education. I am, Sir, yours faithfully,

Bridewell-place, New Bridge-street, E.C., JOHN RUSSELL.  
Oct. 17th, 1892.

If Mr. James Wheeler (Ifracombe) will forward a sample of the preparation it shall be examined and tried.

Mr. G. Rincey.—Apply to the Secretary of the Anti-Tobacco Society.

## THE TREATMENT OF GONORRHOEA.

To the Editor of THE LANCET.

SIR,—Some years ago, when this subject was under discussion in THE LANCET, I advanced the opinion that the most rational, and, consequently, most likely to be successful, mode of treatment was a local one, and gave the results obtained by it. Further experience has proved that those results, which were so favourable as to have their accuracy called in question, were not exceptional, and that the view upon which the treatment was based was correct.

I am, Sir, yours very faithfully,

Leeds, Oct. 17th, 1892. PHILIP FOSTER.

Mr. F. Young will find the corrections made in Dr. Johnson's letter in another column.

Sellers is referred to a medical agent for the information he desires.

## A SUGGESTION.

To the Editor of THE LANCET.

SIR,—Now that so much discussion is going on in your journal as to the relative merits of the different Medical Examining Boards, it would be very interesting to know where the successful candidates at the late Navy, Army, and Indian medical examinations studied and passed.

I am, Sir, your obedient servant,

Dundee, Oct. 7th, 1892. APO MORPHIA.

## SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year.....£1 12 6 | Six Months .....£0 18 8

TO CHINA AND INDIA ..... One Year, 1 16 10

TO THE COLONIES AND UNITED STATES.. Ditto, 1 14 8

Post Office Orders should be addressed to JOHN CROFT, THE LANCET Office, 423, Strand, London, and made payable at the Post Office, Charing-cross.

Notices of Births, Marriages, and Deaths are charged five shillings.

Cheques to be crossed "London and Westminster Bank."

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on page 2, which not only affords ready means of finding any notice, but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed. Advertisements are now received at all Messrs. W. H. Smith and Sons' Railway Bookstalls throughout the United Kingdom, and all other Advertising Agents.

Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher.

Agent for the Advertising Department in France—J. ASTIER, 67, Rue Caumartin, Paris.

## Clinical Lecture

ON

## TUMOURS.

Delivered in the Liverpool Royal Infirmary, July 26th, 1882,

By RUSHTON PARKER, B.S., F.R.C.S.,

PROFESSOR OF SURGERY IN UNIVERSITY COLLEGE, LIVERPOOL.

THE word "tumour" is familiar throughout the scientific world. In English, French, and Italian the spelling differs only by a letter or two from that of the Latin "tumor," which is preserved unchanged in Spanish and by a large proportion of English-speaking persons. A tumour is a swelling or lump, and these three names are applied, in medical practice, to morbid conditions in which increase of size is a feature. Every enlargement is accordingly a tumour, which, on complete investigation, will invariably be found to be one of the following things:—

1. A *distortion or displacement*: as in a hernia, a fractured or dislocated bone, ruptured muscle or other organ, and in some congenital deformities. A *distension*: as an over-filled bladder, intestines, &c.; an aneurism, a varix, a hydrocele. In some such sense a hæmatoma or blood extravasation must often be considered.

2. An *obvious inflammation*: as in abscess, especially chronic; in rheumatic enlargement of bones, and other indurations.

3. A *local hypertrophy*: as in congenital enlarged toes or foot, congenital moles of the skin, elephantiasis, hyperostosis (?).

4. A *tumour proper*.

Though every tumour necessarily falls into one of the above four categories, it is by no means always easy, or even possible, to be certain which that category is. For various reasons, the many elaborate definitions that have been devised with the view of representing exclusively those new formations or neoplasms that are reckoned among tumours proper are unnecessary, since every specimen in the above list of morbid conditions is confessedly called a tumour in practice, both before and after recognition. They are, moreover, useless, since not one of these definitions successfully describes the fourth group in language that invariably excludes the other three.

1. In the first class a hernia, a dislocation, or an over-distended bladder are capable of certain distinction from tumours proper. Yet a hydrocele of the tunica vaginalis or spermatic cord is a pathological effusion of fluid into a cyst that should be empty or absent. Is it an accidental physiological "distension" of Class 1, or is it a well-ascertained "inflammation" of Class 2; or is it without ascertainable cause, and a form of cystic "tumour proper" of Class 4? Again, an atheromatous sebaceous tumour is physiologically due to retention and accumulation of sebaceous secretion, closing, over-distending, and thickening a cutaneous gland, converting it into a more or less globular cyst. It is confessedly regarded as a cystic variety of tumour proper; yet its causal resemblance to hydrocele is very close, and the distinction of either from an over-filled urinary bladder is one of degree rather than of kind.

2. Among "obvious inflammations," a chronic abscess and a glandular enlargement are capable of a recognition, that if not clinically easy or immediate is ultimately certain on dissection. A fluid distension of a patellar or other bursa is a purely inflammatory phenomenon, which subsides on the application of suitable treatment, with or without previous evacuation; yet a fibrous thickening of the same bursa, though equally of inflammatory origin, may fail to disappear on the removal of irritation. There is something of the nature of "hypertrophy" in the increase of fibrous growth or production; though for all essential purposes it is called a tumour proper. Yet the clinical features and many

No. 3087

of the pathological phenomena of certain tumours called malignant partake so strongly of the inflammatory type as to call for detailed comparison presently under the proper head.

3. Enlargement of bone, the obvious effect of inflammation, and similar enlargements called hypertrophy or hyperostosis, are constantly and inseparably blended with bony "tumours proper," from which they cannot always be distinguished, and with which they must often be identified. Is a pedunculated exostosis, produced by acrogenous ossification of its cartilaginous tip, an instance of "displacement," in the period of growth, of a fragment of epiphysal ossifying cartilage? Is it an example, in addition, of "hypertrophy" of cartilage, of bone, or of both? or is it, when finished, a "tumour proper," whether as a pedunculated exostosis, or as a great "enchondroma" with so proportionally inconsiderable a bony pedicle as hardly to suggest its similar origin and mode of growth? Who is to say? Except obvious inflammation, all the above categories may claim it.

4. Tumours proper are of many kinds, and must be classified for systematic discrimination, and for the mutual assistance of observers. Such arrangement as may be from time to time adopted for this purpose depends upon a variety of considerations, summed up in the purport and ultimate result of a tumour in its natural course, or in that modified by interference. Some tumours give little or no inconvenience, being harmless excrescences when situated in parts ordinarily concealed by the clothing, or, if exposed, being at worst unsightly. Others that may be painless are inconvenient deformities, whether concealed or exposed, attaining an excessive size and weight, the physical incubus of which is scarcely mitigated by an associated slowness of growth. But pain, though generally, is not always absent from otherwise non-injurious tumours, and those that are painful happen to be usually small and sometimes diminutive, not seldom suggesting, from their situation in or beneath the skin, the probable entanglement of nervous filaments. The situation of an otherwise harmless growth, as, for instance, beneath the tongue, in the orbit, or displacing the windpipe, may imperatively demand its removal. Finally, the skin over an innocent tumour now and then becomes ulcerated, with risk or loss to life through hæmorrhage or blood-poisoning. Such catastrophes are but indirectly associated with the morbid growth, and are, in fact, more or less accidental complications, which may accordingly be avoided.

These, then, are the attributes of benignancy, as contrasted with those of malignancy, next to be considered. All tumours proper are either benignant or malignant. The former are local abnormalities that have no inherent tendency to endanger life, and frequently fail to inconvenience their possessor; while the latter, though occasionally perfectly curable by operative removal, are always dangerous, and, though often temporarily checked with the effect of prolonging life, are only too frequently rapidly or hopelessly fatal. The size of a malignant tumour may be little or no guide to its nature, or measure of its danger. Rapidity of growth, however, is an almost constant feature, rendering them all conspicuous, and giving to their proportions, if at all huge, a significance that is sometimes appalling. There is a special inveteracy in their growth, evinced in varying degrees and modes—(a) Ulceration of the integuments, over malignant growths, is a conspicuous though not invariably feature. The attendant exhausting complications, blood-poisoning, hæmorrhage, and pain, though often as adventitious as in their more exceptional occurrence in the benign, assume by their frequency quite an integral importance. (b) A liability to reappear near the seat of removal, even after what has seemed to be thorough excision; suggesting the neighbouring existence of infective particles which, though undiscovered by the naked eye and microscope alike, are still suspected to imbue the tissues or fluids. (c) An infective spread to, and inveterate infiltration of, the lymphatic glands pertaining to, and draining, the seat of primary growth. (d) A dissemination in viscera, serous membranes, or subcutaneous and interstitial connective tissues, of tumours identical in most particulars with a primary original growth, which latter, though almost invariably obvious, occasionally eludes discovery. These disseminations are believed to be embolic, the infective particles being conveyed in the blood-stream and lodged in the arterial or capillary system, growing into tumours after their arrest. Some evidence is circumstantially furnished in the form of

R

thrombi, composed of the tissue of malignant tumours, that are sometimes found filling neighbouring veins of various sizes visible to the naked eye, and that may be often presumed to similarly invade smaller veins that are not thus visible. Microscopic investigation has, moreover, revealed the actual presence of malignant emboli, impacted in minute afferent bloodvessels of viscera; proving to demonstration both the fact of conveyance and its mechanism.

Now, ulcerated swellings of the lip or tongue, the face or cheek, skin, or mucous membrane, due to cancerous invasion, to syphilitic infection, or to non-specific inflammatory induration, have resemblances conspicuous and puzzling to all, sometimes temporarily misleading the ripest experiences, and therefore undeniably real. The clinical import, various in name and in course, is eventually clear in most instances, but the anatomical comparison, pushed to its furthest histological limits, not merely confirms the characteristics of divergence, but clenches the identity in points of resemblance. A simple inflammatory induration subsides on the discontinuance of the physical irritative cause, a specific infection of syphilitic influence as truly disappears by exactly similar means, or by the organic administration of a constitutional chemical antidote, or by both. The physiological aberration in simple inflammation, due to the irritation of mechanical agency, is reproduced in the infective forms, where the irritative effects of a specific virus, as a parasitic organism, when known at all, are chemically and otherwise manifested. Such are the exudations of pyæmia, of syphilis, of tubercle. The visible products of malignant disease suggest comparison with those of infective inflammation. They are more luxuriant than the simple inflammations, but incapable of undergoing absorptive resolution on the removal of irritation. They are exempt from suppuration, except, apparently, in the added complication of putrid irritation, but are amenable to no ascertained system of antidotal medication, and share with tubercle the necessity of removal as the sole accessible means of practical cure. They appear, especially in the case of some sarcomata, to partly owe their commencement, mysteriously but almost undeniably, to the operation of local injury, in which respect "acute traumatic malignancy" resembles infective inflammation, such as acute necrosis and, perhaps, caseous tubercle [of bone. In anatomical structure malignant tumours conform largely, and often strictly, with inflammatory type; in superficial features, in physiological infection, and in much of their clinical inveteracy, they resemble products of known parasitic agency. There lacks only the discovery of a visible parasite to complete the analogy.

#### *Classification of Tumours proper.*

Accumulated observations of the external appearances, general behaviour of tumours, their localities, physiological development and anatomical structure have resulted in attempts at classification, truly reputable in their day, but necessarily changing with the advance of knowledge, and proving eventually more or less unsatisfactory in phraseology, if not in fact. The diseases remain the same if their names have been changed, though by fresh discoveries they seem sometimes to be multiplied, at others to be reduced in number. Some of the names, too, have undergone changes of meaning; so former terms and their previous significations must be noticed for purposes of interpretation. Among benign tumours the names explain themselves and their possible synonyms; it is in a portion of the malignant series that confusion has arisen. The classification of tumours according to their anatomical structure, associated with the name and times of John Abernethy, was a memorable step in naked-eye procedure. The refinements of the same principle, effected in the microscopic era, have celebrated the name of Virchow and of his contemporaries at home and abroad. The resolute appreciation of all clinical features, and a refusal even to admit anatomical distinctions except in subordination to the former, are at once most conspicuous characteristics of the example and teaching of Billroth, and a tribute to all that is excellent in cultivated empiricism. By employing two methods of classification in alliance, instead of preferring or excluding either, there has latterly resulted a systematic arrangement of all tumours proper, the malignant apart from the benign, assorted in anatomical sequence. The best statement of this kind is probably that which appeared in 1877, in the seventh edition of Erichsen's Surgery, found also in all essential outlines in the subsequent edition of Green's Pathology, and

of Holmes' smaller work. The following table is prepared, with slight alterations, from Erichsen's account.

Benign tumours are divided into—

#### I. Cystic tumours in general.

##### (1) retention cysts.

##### A. In glands or their ducts.

Cutaneous (sebaceous), as wens or atheromatous tumours, including "horns."

Mucous (mouth, vagina, &c.):

Glands of Bartholin—Cysts of vulva.

Glands of Cowper—Male perineal cysts.

##### Larger glands:

Salivary—Ranula.

Mammary—Simple cysts.

##### B. In ductless glands or cavities.

Bursæ—Hydrocele, housemaid's knee, bunion.

Sheaths of tendons, ganglion—Liquid, fibrinous, fibrous.

Ovary or thyroid gland—Simple cysts.

##### (2) Newly formed closed cysts.

##### A. Dermoid, congenital tumours.

(a) Sebaceous, placed away from seat of sebaceous glands.

(b) Ditto, with wall of true skin structures, glands, hair, &c.

(c) Containing teeth, bone.

##### B. Serous, simple cysts.

Congenital, as hydrocele of neck or shoulder. Arising in solid tumours.

##### C. Proliferous, compound cysts, of ovary and elsewhere.

##### D. Blood-cysts—Hæmatoma, hæmatocela.

(The same occurring in solid tumours.)

##### E. Parasitic cysts—Hydatids.

#### II. Tumours composed of one of the modifications of fully developed connective tissue.

Fat—Lipoma.

Fibrous tissue—Fibroma.

Mucous tissue, like that of umbilical cord or vitreous humour—Myxoma.

Cartilage—Chondroma, enchondroma.

Bone—Osteoma, exostosis.

Tooth—Odontoma.

#### III. Tumours which resemble in structure, more or less perfectly, one of the more complex tissues of the body.

Muscle—Myoma, myofibroma, as in uterus, prostate, &c.

Nerve—True neuroma.

Blood-vessels—Angioma, nævus, also called cavernous or erectile tumours.

Lymph-vessels—Lymphangioma.

Lymph-glands—Lymphadenoma.

Papillæ (of skin or mucous membrane)—Papilloma, or wart.

Secreting glands—Adenoma.

##### A. Myeloid tumour of bone (*see* Sarcomas).

#### Malignant tumours are divided into—

IV. Sarcomas, or tumours composed of tissue which is either purely embryonic, or is undergoing one of the primary modifications seen in the development of adult connective tissue. Arising in connective-tissue layers and interstitial spaces, such as fasciæ, periosteum, bone, marrow, adipose tissue, corium, submucous tissue, the framework of secreting glands, and lymph glands.

##### Present names.

##### Older names.

A. Myeloid or giant-celled sarcoma. (This variety alone is non-malignant.)	} Myeloid, fibro-plastic tumours (in some cases).
B. Spindle-celled sarcoma. Fasciculated sarcoma.	
B*. Spindle-celled melano-sarcoma.	} Fibro-plastic tumour (as generally understood). Recurring fibroid.
Or Melanotic } Spin.-celled Or Pigmented } sarcoma.	
C. Round-celled sarcoma.	} Melanosis, melanotic cancer, fungus hæmatodes.
Alveolar sarcoma.	
Fibro-sarcoma.	
Lympho-sarcoma and malignant lymphadenoma.	
	} Encephaloid cancer. Medullary sarcoma or cancer.

Round-celled coma.	melano-sar-	} Melano-sis, melanotic cancer, fungus hæmatodes.
Melanotic Pigmented	Round-celled sarcoma. Alveolar sarcoma.	
Myxosarcoma.		
		} Probably often called colloid cancer.

V. Carcinomas, or tumours composed of cells of an epithelial type, arranged in spaces in a stroma consisting of more or less perfectly developed fibrous tissue. Arising in and consisting largely of cutaneous, mucous, or glandular epithelium.

- A. Cutaneous epithelioma of skin.  
Cutaneous epithelioma of lip, anus, &c.  
Cutaneous epithelioma of prepuce, glans penis, vulva, &c.
- B. Mucous epithelioma of tongue, gums, mouth, fauces, gullet.  
Mucous epithelioma of stomach, intestine.
- C. Glandular cancer of breast, pancreas, and other glands.

#### *Sarcomas of Bone.*

Any of the malignant sarcomas may arise in the fibrous covering of bones, their names being then preceded by the additional word "periosteal." Or they may arise in the central fat, whether of cancelli or of tubular marrow. In any of these central tumours may be found giant-cells or myeloplakes; sometimes so abundantly as to give the growth a resemblance to ordinary myeloid, microscopically, though differing in all other respects. The following sarcomas are peculiar to bone, and may be of either central or periosteal origin: osteoid chondro-sarcoma, osteo-sarcoma or ossifying sarcoma, both otherwise known as osteoid cancer. Carcinoma never arises primarily in any bone, but invades it secondarily either by contiguous spread from another primary source (as skin, tongue, mammary gland, &c.); or as a reproduction by distant conveyance in the circulating fluids.

#### *Mammary Tumours.*

As to the causes of tumours proper, many of them among the benign are known to be either congenital or developmental excrescences, as for instance—1. Dermoid and other congenital cysts in the permanent or temporary orifices, or in the cavities and organs of the body. 2. Pedunculated cartilaginous exostosis. 3. All nævi, warty and pigmented

cutaneous moles. But a notion has arisen, and has been treated of by Cohnheim, that tumours have their origin in portions of embryonic tissue lying in the numerous interstices of the body, and undergoing the developmental alterations necessary to produce them; a form of growth which, in the case of simple solid tumours, is a mere repetition of that which occurred in the completed tissues which they imitate or exactly resemble. This notion has been so far supported by experiment that fragments of embryonic cartilage, transplanted to the aqueous chamber of the eye, to the peritoneal cavity, and into the stream in the jugular vein, have grown into cartilaginous tumours, whereas fragments of completed periosteum and hyaline cartilage, similarly dealt with, grew only for a time, and eventually underwent absorption. The notion, though quite as yet unproved, is interesting, if not important, affording a credible and comprehensible mode of accounting not only for all solid and some cystic benign tumours, but possibly malignant too, for, when considered along with a supposed anatomical alliance with inflammation of a possibly infective type, and with the strongly suspected "traumatic" excitation of "malignancy," one or other, and sometimes all, of these hypothetical explanations may be applicable to the origin of the groups sarcoma and carcinoma in completion of the idea. In fact, evidence is not wanting in support of some such idea in the case of certain instances of "branchial carcinoma," related by Volkmann (*Centralblatt f. Chir.*, Jan. 28th, 1882). This term he has applied to examples of deep, primary carcinoma of a distinctly cutaneous epithelial composition, excised by him from the stylo-hyoid region, and supposed to have arisen in epidermic structures included at the obliteration of the branchial clefts.<sup>1</sup> Among the tumours of the breast preserved in this museum is one (F. 30) of cystic nature, excised with the whole gland. The soft contents had the naked-eye appearance which characterises some softened epitheliomatous swellings, especially when secondarily affecting lymph glands, and the cyst wall was found by Mr. Paul to show the microscopic structure of unmistakable cutaneous epithelioma, an opinion which I entirely confirm from inspection of the slides. Such a product is extremely uncommon if not as yet unique, and not accounted for on any plan that has yet been devised to explain the origin of tumours, except the one now referred to. One may imagine a congenital or developmental aberration of cutaneous tissue, such as might form a small sub-cutaneous or even intra-mammary "dermoid cyst," however minute, subsequently undergoing the same transformation into epithelioma that any previously healthy cutaneous part would have to undergo when invaded by this disease. The same may apply to sarcomas, and may account for their hitherto mysterious appearance in the numerous connective tissues and interstitial spaces of the body. Their relation to congenital structures is so far known that a cutaneous pigmented mole may in after life be the actual and only seat of sarcomatous infiltration. Such a specimen is mounted in this museum. It is said that, under circumstances such as these, the usual malignant course is not manifested, though the structure be identical with that seldom unattended otherwise by recurrence, infection, and fatality.

<sup>1</sup> I have also met with one case of this kind, and have the microscopic slides prepared from a deep primary cutaneous epithelioma, removed some years ago from the left side of a middle-aged man's neck by Mr. J. P. Harris, assisted by me. The thing had puzzled me until I saw Volkmann's paper.

THE GUILD OF ST. LUKE.—The annual chapter of this Church Guild for medical men and students was held on Tuesday evening, Oct. 17th, at the English Church Union Rooms, Wellington-street, Strand. The Provost, Dr. Alfred Meadows, presided, and after reviewing the work of the year past, announced his intention of resigning his office, to the unfeigned regret of all present. The Treasurer, Dr. Holman, read the report for the year. Mr. George Cowell was elected Provost, Dr. Meadows Vice-Provost. Dr. Holman was re-elected Treasurer, and the Rev. G. Greenwood, Warden. Mr. A. K. Willis, Gascony House, West-end lane, N.W., was elected Secretary. On Wednesday (St. Luke's day) there was a celebration by the Warden at St. Thomas's, Regent-street, at 8 A.M. Afterwards the members sat down to breakfast at the residence of Dr. Meadows. Festal evening was sung the same day at St. Paul's Cathedral by a choir of the London Gregorian Choral Association.

# Introductory Lecture TO THE COURSE OF SURGERY IN THE UNIVERSITY OF EDINBURGH.

*Delivered Oct. 24th, 1882.*

By JOHN CHIENE, M.D. EDIN.,  
PROFESSOR OF SURGERY.

THE Chair of Systematic Surgery in the University of Edinburgh is of comparatively recent foundation. The cause of this is not far to seek. For many years it was held conjointly with the Chair of Anatomy. As the range of anatomical science increased in scope and importance, and when in 1736 the foundation of the Royal Infirmary by the Royal College of Physicians brought more prominently forward the practical aspects of surgical teaching, it was evident that the double work was too great for any one man. The Royal College of Surgeons early recognised this necessity, and in the interests of surgical science they petitioned the patrons in 1777 to found a separate chair. It was not, however, till the year 1831 that a Chair of Surgery was founded, and J. W. Turner was elected professor of surgery. He was succeeded in 1836 by the great physiologist and scientific surgeon, Charles Bell. He, in his turn, was succeeded in 1842 by James Miller; and on his death in 1864, James Spence, whose loss we now mourn, became professor of surgery. I well remember Mr. Spence's introductory lecture, delivered in this class-room eighteen years ago, before a crowded audience of students, former pupils, and friends: his leading thought—the gradual growth of surgical science; his subject—the Edinburgh School of Surgery. He laid special stress on the influence of John Bell and Robert Liston. Of John Bell he says, "He was no ordinary man, but a real surgical genius, of great natural talents, and imbued with that enthusiasm which is a mark of genius, and which does so much to create enthusiasm in others." Of Liston he says, "As a bold, and cool, and dexterous operator, I have scarcely seen his equal. His great power in diagnosis, the wonderful faculty he possessed of perceiving, as if by intuition, the true nature of a case in all its bearings, and of adopting adequate measures for its treatment was such as are rarely to be met with." Syme and Fergusson were then alive, and the time had not yet come to form an estimate of their great power for good. William Fergusson had gone to London, and was at that time at the height of his fame as a skilful surgeon, a brilliant operator, and, above all, a kind friend and adviser to anyone from Scotland. Of this I have a very pleasant recollection, when, in 1867, he gave me sound advice in what was probably the turning point of my career, advising me to stay in Edinburgh, and not to migrate south as so many of my countrymen had done. He never forgot the land of his birth. James Syme was then the leader of Scottish surgery, of whom it might truly be said in the words of that good kindly man, the author of "Rab and his Friends," "He was, I believe, the greatest surgeon Scotland ever produced." "He had that quality of primary minds of attaching permanently those he had relation to, his students never ceased to love him, and returned to him from all regions of the world." As one of his pupils may I be permitted, in John Brown's words, to say, "Of what he was to me—his patience, his affection, his trust, his wisdom, and still more, what he might have been to me had I made the most of him,—it is not for me now to speak. He remains in my mind as one of the strongest, clearest, capablest, most valuable understandings; one of the warmest, truest hearts I have had the privilege and the responsibility of knowing." It has often been a matter of surprise to me that Syme's works have never been re-issued in a collected form. They will always be classical. I feel sure of this that there are many of his old pupils who would gladly undertake the task. Mr. Spence, in his introductory lecture, pointed out to us, his students, the great importance of anatomy and clinical study, of the dissecting-room and

the hospital ward. He could speak with authority on these points, because he had been for many years a teacher of anatomy, and for fifteen years a surgeon in the hospital and lecturer on surgery in the extra-mural school. When we remember that Charles Bell held the Chair of Surgery in this university, physiology must always play an important part in the surgical teaching. With our vivid recollection of the complete mastery James Spence had over all the details of anatomy, we can never forget the paramount importance of anatomical dissection as the basis of surgical practice.

As many of you know, it has been my endeavour, during the last twelve years, to teach the principles of surgery from a physiological standpoint, the practice of surgery from an anatomical point of view. While I certainly shall have difficulties as to the best way fully to utilise and develop the great opportunities for good which my present position affords, one thing I feel sure of is this, that in the future there will be no necessity for any departure from the method of teaching that I have always hitherto followed. I shall be encouraged, in so doing, by the remembrance that I hold a position previously occupied by Charles Bell and James Spence. It was my good fortune to be the pupil both of James Miller and James Spence. Miller, an eloquent lecturer, a brilliant operator, and a kind-hearted man; Spence, the representative, for some years before his death, of Scottish surgery, the careful and painstaking surgeon, whose skill as a diagnostic surgeon was unrivalled. You know how well he did his work as your professor; he never forgot—what has ever seemed to me the reason why Edinburgh attracts so many students,—that teaching was his primary duty. His daily lecture, his hospital visit, were to him a time sacred to learning and teaching, and not to be lightly interfered with by the calls of practice, however urgent. You know how hard he worked; of late the troubles of declining years interfering in no way with that thoroughness in all he did, and that daily round of arduous duties, the performance of which was to him his chief pleasure and his life-work. I would desire to remind you of his avoidance of all show. I recall at the present moment the early days of the winter session of 1862, the operating theatre in the Old Infirmary, Spence evidently pre-occupied, restless, and excusing his restlessness by an occasional glance at the instrument-tray, as if every knife and every needle had not been carefully examined and arranged by himself; the theatre crowded to the ceiling, a small sprinkling of practitioners amongst a host of students. The juniors, of whom I was one, were somewhat anxious, and perhaps not over-confident of their staying powers; the seniors, who had left the medical house to visit their old haunts and see "Spence operate," were there in great force, some perhaps thinking of the time when they were juniors, with heart-searchings of time misspent, never to be recalled, others in whispered comments recalling some dreadful operation which they had witnessed, patrouising, but withal in a kindly fatherly manner, us juniors. The patient was soon brought in, a pale but healthy middle-aged woman. She suffered from a large tumour of the neck. I need not detain you with an account of the operation; the time seemed to me short—it must have occupied an hour. During all that time Spence went on with his work quietly; little was said, but gradually the large growth, separated from its attachments, became more and more apparent, until at last it was removed, and a gap was left, exposing the carotid vessels and the internal jugular vein from the angle of the jaw to the clavicle. That large blue vein is still vividly before me. I remember my only thought was, that man must be a good anatomist. This was my first lesson from James Spence; since that day it has been my great privilege to receive from him very many practical lessons and much kindness. It will be an evil day for the teaching of surgery in this school when the useful lessons which Spence taught are forgotten by his pupils. He was a good practical surgeon, a kind friend, and an honest man. In his "Lectures on Surgery" he has left us a guide which will always be eminently trustworthy, more especially in those branches of practical surgery to which he devoted special attention. His chapters on hernia, aneurism, diphtheria, croup, stone in the bladder, their diagnosis and treatment, are to my mind full of sound advice, and will always be read and acted upon, and Spence's name will be handed down as an authority in practical surgery.

The term "introductory" may refer either to the lecturer or to his subject. Personally I am pleased to feel that I require no formal introduction. May I then be permitted to

utilise what remains of this hour, and make it a part of the course on which we are now entering? I have no desire that this lecture should in any sense be of the nature of a pastime, but that to-day, as I trust in every lecture this session, something will be learned by you and by me. To be useful, what I have to say must be more or less elementary; for this I cannot but feel that I owe an apology to those present, old friends and former pupils, who come here to welcome me in a new position, and to other kindly critics present, who have perhaps finished or are now finishing their university course. While my remarks are more especially addressed to students of the second year who are commencing the study of surgery, I am well aware that there are some present fresh from school life who are only now beginning their medical studies, and who as yet consider it a privilege to attend an introductory lecture, and who can still enjoy their comparative freedom as university students, comparing it favourably with the rigour of school discipline with which very lately they were so well acquainted. May I as a friend say to them a passing word? In your present freedom there is a great danger: see that you use that freedom aright. Remember that you are now university men. Your school looks to you to be a credit to your up-bringing; your university hopes in the future to be proud of you. Take this to heart, that your future prosperity very much depends on the way you spend your first year here. I earnestly entreat you to take great care what friends you now make. You will most certainly be tempted. Learn then, above all things, to be able to say "No;" that is the whole business, and I have no fear of the result. "Read carefully; do not be satisfied with a superficial understanding of a book, nor hastily give your assent to those who talk too much."

Pardon me for this short digression; I could not help it. I have seen in my day many bright beginnings end only in disaster, self-reproach, and home misery. My audience is a large one; perhaps what I have now said may be of use to some one junior student now present.

The healing of wounds has from the beginning occupied the attention of surgeons. Rapidity of healing and freedom from pain during the process have mainly been sought after in their treatment. In saying a few words regarding wounds, I would first direct your attention to the treatment of a wound twenty years ago, when I was a student, comparing it with its treatment at the present time. I necessarily, in my comparison, take the practice of the school with which I am most familiar. Its practice, however, has always been a pretty good gauge of the work of practical surgeons. I do not wish to say that it has been foremost, but certainly it has always been among the first to institute or to adopt any improvements. Twenty years ago, as at present, there were differences of opinion in minutiae, but the practice of the majority at either period will be taken as the basis of our comparison. I will have no difficulty in showing that most remarkable alterations have taken place; and I will then ask you to look into the past history of surgery, and I think be able to show you that the present practice has been more than foreshadowed, and that much that is now done has been done long ago. In some minds there seems a tendency to dwell upon the so-called ignorance of our forefathers. I would assert the very opposite, and say that there were clear-headed, shrewd, and intelligent surgeons in those days who can most favourably be compared with the present generation. This assertion, if just, is a comforting one, and may encourage us to hope that any honest, truthful work that is now being done will be appreciated by our successors. If then I can show that the present practice of surgery is a revival of what was done in the past, it will be my endeavour in the next place to point out the real difference, and to show that, while surgeons formerly worked empirically, we are now working on a scientific basis.

The present practice and its results on general surgery will occupy our attention during the coming session. While I have no desire to prophesy concerning its influence in the future, or to predict its permanency, I would suggest, that if I can show that the whole history of practical surgery has been more or less an empirical struggle to overcome difficulties and dangers, the primary cause of which is now clearly understood, then this fact encourages the belief that the present change, in so far as it is founded on a scientific basis, will be a permanent one. The practical details will most certainly change—are in fact daily changing—and will be improved while the great primary truth on which it is founded will always be our standard. There is a great law

governing our physical and mental well-being—namely, that growth and development are accompanied by change, that to stand still and make no advance must necessarily soon be followed by physical and mental decay. Twenty years ago in the treatment of any large recent incised wound, the bleeding arteries were tied with well-waxed silk ligatures. The ligatures were left long and brought out at the corners, or at the most dependent part of the wound. Plenty of cold water was used to wash the wound; the edges were brought together with silver stitches, and a piece of dry lint was laid over the incision and retained in position by a bandage. As a rule this dressing was not touched till the second or third day, when it was removed in consequence of local uneasiness. This removal was always accompanied by a certain amount of pain, which was modified by soaking the lint with warm water before removal. Occasionally, in consequence of the absence of uneasiness, the lint was untouched for a longer period, and removed at the end of a week or ten days to find that union by the first intention had taken place, except at the point or points where the silk ligatures emerged. Sooner or later these ligatures became loose and were removed one by one, when complete healing occurred. The uneasiness complained of was due to local tension as evidenced by redness of the lips of the wound. This redness and uneasiness were relieved by bathing with warm water, or by the application of warm-water dressing (lint and gutta-percha), or by the removal of a stitch or stitches, when the confined discharge escaped as pus. If this pus had a disagreeable odour, then the cavity of the wound was gently washed out with a syringe filled either with simple warm water, or with warm water tinged with Condy's fluid. The wound was dressed night and morning, sometimes even more frequently, and gradual consolidation by means of union by the second intention took place. I make no allusion to the constitutional dangers of which every now and then sad examples occurred, sometimes epidemic, sometimes epidemic, except to say that the principal danger, termed pyæmia, was looked upon as in great part due to the constitution of the patients. The treatment of this danger was entirely curative—quinine, iron, and stimulants were freely administered. Prophylaxis did not occupy the practical mind, because the primary cause of the condition was unknown. Nowadays the treatment of a recent incised wound, as most of you know, is very different. The vessels are tied with catgut instead of silk, the ends of the ligatures are cut short, and we see no more of them. The wound is thoroughly washed with an antiseptic lotion, and a drainage-tube, a hank of catgut or of horsehair, is introduced to the bottom of the wound and brought out at a dependent point. The wound is stitched and a dressing is applied, the essential feature of which is that it contains some antiseptic. This dressing is not interfered with until the discharge soaks through it, or appears at its edges, or unless the wound is painful. This pain is due to an imperfect application of the drainage. The wound is never exposed to the air, but is examined under cover of a cloud of antiseptic vapour. The wound, as a rule, heals without suppuration and without pain.

Here, then, we have two very different pictures: the main differences between them seem to be, ligatures of catgut instead of silk, free drainage, and antiseptic precautions. Are any of these methods really new? *Physic* of New York, Astley Cooper, and others, used catgut; John Vigo and Ambrose Paré recommended drainage-tubes; Würtz alludes to drainage by means of a hank of horsehair; Guy de Chauliac, Vigo, Arcæus, Würtz, Purmannus, Ambrose Paré, Colbatch, and others used various antiseptics—turpentine, alcohol, camphor, myrrh, and various resins. External dressings were applied containing antiseptics. Watson Cheyne, in his recent valuable work on "Antiseptic Surgery," speaks of Arcæus's treatment as "a fair antiseptic method, and not far removed from an aseptic one." These surgeons whom I have named flourished between 1350 and 1750. During these centuries we find, in the great majority of the surgical works, that much stress is laid upon putrefaction. We find, for example, that Guy de Chauliac, Vigo, and Woodall, define a wound as a solution of continuity—fresh, bloody, and free from putrefaction; and they speak of their remedies as of use in preventing and curing putrefaction. Not only do they mention putrefaction as an evil thing, but we find that Paré, Würtz, Magatus, Colbatch, Belloste, Heister, Benjamin Bell, Alexander Munro, and Abernethy, all considered that the entrance of air into the wound is in some unknown way associated with inflammation

and unsatisfactory healing; while Paré and Magatus, in the beginning of the sixteenth century, tell us that the air is charged with miasms, and warn us to avoid such air. In consequence more especially of the teaching of John Hunter and John Bell towards the end of the last and the beginning of this century, these views with regard to the evil effects of the air were almost lost sight of. In consequence, more especially of the teaching of Syme and Liston, simplicity of dressing, such as I have described as made use of in 1860, was the rule in surgical practice. At the same time it is to be noted that the valvular openings recommended by Abernethy, the aspirator long ago recommended by Delacroix and Anel, and subcutaneous surgery generally, retained their place in the practice of surgery. In the beginning of the present century chemists, scientific men, having no knowledge of, and altogether apart from, the practice of surgery, began the study of fermentation, described the products of the process, and searched after the cause. Schwann demonstrated that the oxygen in the air was not the cause, and in 1836 he and Cagniard de Latour discovered independently the yeast plant, and its constant association with alcoholic fermentation. After a time this plant was shown to be the cause of the alcoholic fermentation. Pasteur, in 1858, made the next great step, and pointed out that putrescence is a form of fermentation, and brought forward the doctrine that this is due to organisms planted in a putrescible substance. This doctrine has, up to the present day, been termed the germ theory of putrefaction. This theory is now proved to be correct, and as we speak of Newton's Law of Gravitation, so I am of opinion that we are now in a position to speak of Pasteur's Law of Fermentation. All this work, it will be observed, was done by scientific men, apart from and apparently unconnected with the practice of surgery. For some years before 1860 there were various indications that this scientific work was soon to be utilised in surgical practice, and there can be no doubt that to Lemaire the credit is due of having first seen the connexion. He used coal tar and carbolic acid as disinfectants in wounds. It is unnecessary to inquire the reason why the work of Lemaire did not gain general acceptance. The fact undoubtedly exists, that his ideas were not adopted by the majority, and that they were even abandoned by those surgeons who had given them a trial.

(To be concluded.)

## RUPTURE OF THE URINARY BLADDER.<sup>1</sup>

BY WALTER RIVINGTON, F.R.C.S. ENG.,  
SURGEON TO THE LONDON HOSPITAL.

### PART II.

#### SYMPTOMS AND DIAGNOSIS.

THE primary symptoms of rupture of the urinary bladder will be more or less marked according to the condition of the patient at the time of the occurrence. If the sufferer, as is too frequently the case, happens to be intoxicated, he may be unconscious of anything amiss. He may be found lying insensible on the highway, or be picked up in the street as simply inebriate, and be carried to a police station or to the hospital, or walk into an adjoining room and go to bed, or stagger to his home, and only become alive the next morning to the fact that he has sustained a grave injury. If the accident occurs to a sober individual, or to one who is only convivial or slightly tipsy, there will be, at the moment of rupture, intense pain at the umbilicus or in the hypogastrium, or perhaps faintness or complete syncope, and a feeling of something having given way within the abdomen. The sensation of something having given way is common to the traumatic and idiopathic cases. In the majority of instances of intra-peritoneal rupture the power of locomotion is either abolished or very greatly impaired, and, even if the sufferer be able to walk, he will in all probability do so slowly, painfully, in a stooping position, or with the assist-

ance of others. In five cases the power of locomotion seems to have been retained in a more remarkable degree (cases related by Dr. Alfred Taylor,<sup>2</sup> Mr. Hird,<sup>3</sup> Dr. Harrison,<sup>4</sup> Mr. Crossley,<sup>5</sup> and Dr. Gillespie<sup>6</sup>). In Dr. Harrison's case the patient kept about and at work till the fourth day after the injury. At the post-mortem the recto-vesical cul-de-sac was seen to be shut off from the general cavity of the peritoneum by adhesions between the lower intestines and the bladder, and contained a quart of colourless urine. It has been conjectured that the retention of the urine in the cul-de-sac would not be attended with the same immediate disturbance to the system as its diffusion through the general peritoneal cavity. This explanation, though possible, does not appear to me to be so probable as the occurrence at first of a partial rupture afterwards becoming complete. Dr. Max Bartels alludes to the latter method of explanation, and appears to lean towards it.

As soon as the shock, pain, and peculiar feelings occasioned by a ruptured bladder have subsided, the subject of the injury, who had previously felt an urgent call to void urine, and may have been on his way to satisfy the call, experiences, perhaps, a temporary feeling of relief. Very soon, however, he begins to be tormented with a strong and frequent desire to make water. On attempting to do so nothing comes away, but straining may cause a few drops of blood, or bloody urine, to issue from the urethra. Accompanying this distressing condition pain will be felt in the hypogastric region, or there may be constant acute pain at the umbilicus or all over the belly, the pain being intolerable in the erect position. Pallor and anxiety of countenance, restlessness, thirst, difficulty in movement, nausea and vomiting, depression, and feeble pulse will be the evidences of grave constitutional disturbances. The introduction of the catheter draws off blood, or a variable quantity of blood and urine combined, or fails to remove anything at all. Usually the catheter will pass readily enough into the empty and more or less contracted or collapsed bladder. When the point of the catheter impinges on a sound part of the wall it will be found difficult to rotate the instrument and to depress it between the patient's thighs, but if the rent is in the posterior wall, on withdrawing the catheter a little and altering its direction it may suddenly slip through the rent into the peritoneal cavity, become freely movable, and withdraw a large or considerable quantity of fluid. The amount of blood mixed with the urine is variable. The quantity of urine drawn on occasions subsequent to the first introduction will vary according to the frequency of catheterism and the position of the extremity of the instrument. A catheter confined to the cavity of a ruptured bladder will not remove more than a few ounces of urine, rarely, I think, more than four or six at the most, but whenever it traverses the rent half a pint to thirty ounces and even more fluid may be expected to issue. As the contraction of the muscular coat of the bladder no longer assists the flow, and as the abdominal muscles will probably be exerted only for the purposes of respiration, the urine will either well out gradually and run down by the side of the catheter, come out almost *guttatim*, or pass from the instrument in an intermittent stream during the periods of expiration. As a general rule the patient from the first is unable to pass water, and continues to display this inability to the end. In a few cases water has been passed voluntarily by the patient, either at the outset or at some period during the progress of the case. In my fourth case, where the rupture was situated just above the prostate, there was at first incontinence of urine, and in a recent case of idiopathic rupture behind the prostate, brought before the Hunterian Society by Mr. Tay, urine seems to have dribbled rather freely from the urethra.

The primary symptoms which have been enumerated, pain in the abdomen, a feeling of something having given way within that cavity, difficulty in standing and walking, a certain amount of shock or depression, temporary relief to the desire to make water, followed by a more urgent desire but inability to do so, and the results of catheterism in bringing away blood or bloody urine, or nothing whatever, are common both to the intra- and extra-peritoneal ruptures. Here, however, the two classes of cases diverge from each other. In the intra-peritoneal ruptures the symptoms are decidedly more severe. The shock at first is greater, and the symptoms of peritonitis, as a rule, set in within a few hours and increase in severity. Only in a severe injury is

<sup>1</sup> The particulars of the reported cases of recovery and illustrations of the statements made in the text are omitted in this abstract, which nearly corresponds to a paper read at the Hunterian Society on Oct. 11th, 1882.

<sup>2</sup> Medical Jurisprudence. <sup>3</sup> THE LANCET, Oct. 3rd, 1836. <sup>4</sup> Op. cit. <sup>5</sup> Med. Times and Gazette, 1872. <sup>6</sup> Ed. Med. Journal, 1859, p. 311.

any external mark of violence likely to be observed. Most probably the abdomen will be found swollen or prominent in front, tender on the slightest pressure, and tympanitic, but in the hypogastric region for a variable distance, and sometimes extending towards one or both iliac fossæ, the percussion note is likely to be dull, more especially in the erect position. There may even be a more or less defined swelling resembling the bladder between the umbilicus and pubes, due to the circumstance that the urine is temporarily confined by the disposition of the coils of intestine. Examination per rectum will elicit tenderness and pain, and in some cases the fingers may be able to detect a collection of fluid in the rectovesical cul-de-sac. As a general rule there is no collection of fluid in this situation. In a typical case of intra-peritoneal rupture the patient will exhibit all the symptoms of peritonitis in addition to those proper to the lesion itself. He will lie in bed with his knees drawn up, or be propped up with pillows to relax the abdominal muscles. He will have a pinched, anxious, haggard expression of countenance, look pale and anæmic, and be tormented with a frequent or constant desire to make water leading to ineffectual efforts to empty the bladder. He will suffer from thirst, and sooner or later be troubled with vomiting, bringing up a greenish-yellow fluid, and even the water which he had drunk copiously to quench his thirst. With vomiting hicough is frequently associated. The pulse will be small, feeble, and rapid, ranging between 90 and 130. The temperature will probably be a little over the normal. The respirations will be hurried, accompanied, perhaps, by dyspnoea, or a feeling of oppression at the chest. The abdomen will be tense, tender, tympanitic above, dull and possibly fluctuating below. The tongue will be furred and dry, and the bowels confined. Occasionally there may be rolling of the intestines and distressing tenesmus. Unless stupefied with alcohol, the patient may be expected to pass the first night after the injury in much torture, vainly endeavouring to procure rest and sleep. Throughout the illness there will be marked restlessness and insomnia. As the case proceeds the symptoms become aggravated; the swelling and tension of the abdomen increase; clammy sweats appear on the skin; the hicough and vomiting become more urgent and distressing; the pain is intolerable; the countenance sunken and ghastly, and the patient may sink into a state of collapse, or a typhoid condition attended with delirium and coma. Not infrequently, after a few days, especially about the fifth or sixth, if the patient survive so long, there are marked signs of amendment. Nature has commenced the repair of the rent in the bladder, and the edges of the rent have become agglutinated or blocked by the sigmoid flexure or a coil of small intestine. The patient passes water voluntarily, takes food without rejecting it, sits up in bed, is free from pain and comparatively cheerful. An error in diet, or a purgative acting on the bowel, or the course of the disease itself, dispels the deceitful improvement, the former symptoms recur, and the patient may expire on the very day which follows the signs of hopefulness and recovery. In one or two cases stercoraceous vomiting has occurred, and in a case at St. Bartholomew's Hospital a coil of intestine entered the rent in the bladder, and gave rise to symptoms of intestinal obstruction which masked the symptoms of rupture of the bladder. In the extra-peritoneal ruptures the symptoms of peritonitis will not be present, unless the peritoneum has been injured by the violence which occasioned the rupture of the bladder, or becomes involved secondarily, either by contact with urine effused under it, or in the course of the diffuse inflammation and sloughing of the sub-peritoneal areolar tissue. In regard to the local symptoms, a less amount of urine may be expected to follow the introduction of the catheter than in the intra-peritoneal ruptures, as the point of the catheter will not readily enter the rent in the bladder. Nevertheless, manipulation with the finger in the rectum may occasionally succeed in causing the point of the catheter to pass through the rent into a pouch outside the bladder, containing urine mixed with blood and the products of inflammation. The situation of the collection will vary according to the position of the opening in the bladder. When the rent is in front, the urine either forms a circumscribed tumour outside and anteriorly to the bladder, occasioning marked dullness on percussion, or it becomes widely diffused, mounting up towards the umbilicus between the peritoneum and the abdominal muscles, or passing into the iliac fossæ, or through the obturator foramina, and the inguinal and femoral canals into the thigh and scrotum. When the

opening is behind the prostate the fluid will ascend into one or other of the iliac fossæ. Wherever extravasation occurs it sets up inflammation in the connective tissue and fasciæ, followed in due time by suppuration and sloughing. Occasionally the urine is collected in a kind of sacculus, the walls of which are composed of connective tissue matted by lymph, simulating the appearance of a lining membrane to the adventitious cavity. The general symptoms will be less marked than in the intra-peritoneal ruptures, and be of the character familiar to the surgeon in connexion with extravasation of urine.

In a typical case the diagnosis will be easy, but it is likely to be obscure if the surgeon cannot obtain a satisfactory history of the case, or where the symptoms are masked or slight, and in which, possibly, the patient has passed water voluntarily, or when it flows from the urethra. The surgeon needs to be constantly on the alert, and to have his mind directed to the possibility of rupture not only where there has been an abdominal injury, but in cases of retention from stricture, or from hypertrophy of the prostate gland, or from any other cause, and where the patient comes under his care stupefied with alcohol. In extra-peritoneal ruptures doubt will soon be removed by the occurrence of extravasation of urine, but in the intra-peritoneal I believe that the best local test is the possibility of passing the point of a long catheter through the rent into the peritoneal cavity, allowing free movement and drawing off a large quantity of fluid. When contrasted with a prior limitation of rotation, and of depression, and the removal of blood, or a very small quantity of bloody urine after the instrument had undoubtedly passed the prostate gland, the sudden slipping of the catheter up to the hilt in the urethra, with the effect stated, is extremely significant. Mr. Heath injected warm water through the catheter, and the stream was distinctly felt by the patient in the groins and abdomen. This means of diagnosis might be used when the surgeon could not make one without it, but it tends to diffuse the urine already present in the peritoneal cavity, and it is probable that the warm water itself may exercise an injurious effect upon the peritoneum. If the bladder is sound, injection of fluid ought to furnish decisive evidence by causing the formation of a circumscribed tumour, which disappears on catheterism with recovery of the fluid.

One great disadvantage of an incorrect diagnosis and mistaking some other form of abdominal injury for a ruptured bladder, or an extra-peritoneal for an intra-peritoneal rent, is that if recovery ensues the case is published with a flourish, and the treatment pursued is quoted as well worthy of adoption in a similar case. In recent years there has been a serious increase in the number of reported cases of recovery after an alleged rupture of the bladder, and several are said to have been ruptures into the peritoneal cavity. Before accepting any case as a genuine instance of recovery after simple uncomplicated intra-peritoneal rupture, the following points should be well considered:—

1. It is desirable to have clear evidence that the bladder was full at the time of the accident. A distended bladder can scarcely escape from a severe blow or contusion of the abdomen, but a bladder empty, or nearly so, and under the protection of the pelvic bones, may elude the greatest violence.

2. It must be borne in mind that the bladder may be merely contused or displaced, and that many of the symptoms of rupture may be present—viz., blood in the urine, inability to micturate with desire to do so, and some difficulty in the passage of the catheter. A case of this kind I have seen, and Mr. Le Gros Clark's case, which has been quoted as an example of rupture, certainly appears to me to be an instance in point. In the history of the case no evidence is adduced to show that the bladder was distended at the time of the accident; the most typical primary symptoms, a feeling of something having given way, a distressing desire with inability to micturate, and the peculiar results obtainable by manipulation after passage of the catheter, were absent, and the quantity of urine removed or passed does not appear to have been at any time defective.

3. Difficulty experienced in drawing off a patient's water, and the necessity for altering the direction of the catheter or the position of the patient before succeeding, cannot be taken as conclusive evidence of a rupture of the bladder. A blocked catheter, hitching in a fold of mucous membrane, a swollen veru montanum, entrance of the point of the catheter into the sinus pularis or a false passage, displace-

ment of the bladder, submucous extravasation of blood, and enlargement of the prostate gland, may all occasion impediments.

4. It is erroneous to suppose that the peritoneum tolerates the presence of pent-up urine. The idea of tolerance appears to have originated partly from the fact that post-mortem examinations of cases of ruptured bladder sometimes detect very slight, if any, traces of peritonitis, and partly on cases which appear to indicate the ability of the peritoneum to absorb effused urine. The basis will not support the superstructure. For if the history and progress of the cases in which pathological peritonitis was absent be examined, all the symptoms of intense irritation and inflammation of the peritoneum will be found, and the issue was death. The presence of absence of lymph, as evidence of inflammation and irritation or the contrary, is little to the purpose. Purulent collections or serous exudation may take the place of lymph, and evidently the tolerance of urine by the peritoneum must be judged not merely by the effusion of lymph, but by the local and general symptoms and by the issue of the case. If the intrusion of urine into the peritoneal cavity produces intense pain, tenderness, and distension of the abdomen, and if these symptoms are accompanied by constant vomiting, restlessness, a sunken anxious countenance, altered temperature, feeble pulse, hurried respiration, clammy sweats and intense prostration, terminating in death, I cannot understand why it should be affirmed that the peritoneum tolerates the presence of pent-up urine because after death it is sometimes found to have retained its smooth glistening aspect, and to be free from undue vascularity, adhesions, and lymph. That the peritoneum may absorb urine effused into its cavity I will not dispute, though I believe that this absorption is slight. But even if it takes place in any quantity, as conjectured by Solly, Le Gros Clark, Max Bartels and others, I entertain no doubt whatever that it exercises a most depressing influence upon the system of the patient, so that the matter may be summed up in this way: However tolerant of urine the peritoneum may appear in some cases of ruptured bladder, intolerance of it is plainly exhibited by the system of the patient. Nor is urine tolerated in the areolar tissue, be it the urine of the infant or the urine of the adult. Both alike, when pent-up in the meshes of the tissue, will set up inflammation, supuration and sloughing, and I distrust altogether any statements which would involve any opposite conclusion.

## A SCHEME FOR THE MORE COMPREHENSIVE STUDY AND PREVENTION OF SO-CALLED ZYMOTIC DISEASES.

By THOMAS M. DOLAN, F.R.C.S. EDIN.

### PROVISIONAL OUTLINE.

THE theory of creative evolution has placed the study of the genesis of species on a scientific basis. The germ theory promises as much for medicine. A richer fruition will result if the germ theory be studied by the light of evolution. We have seen its application in the animal and vegetable world; it has been extended to the sociological aspects of life, &c. It may be applied with advantage to the study of disease. Disease is not an entity standing alone. It should always be considered in its relation to the cosmos. Buckle, in his "History of Civilisation," vol. iii., p. 447, tells us that the great glory of Hunter as a pathologist was that he formed the grand conception of a universal pathology. Buckle says: "With him [Hunter] the science of pathology did not mean the laws of disease in man alone, or even in all animals, or even in the whole organic kingdom; but it meant the laws of disease and of malformation in the entire material world, organic and inorganic. His great object was to raise a science of the abnormal. He determined to contemplate nature as a vast and complicated whole, exhibiting indeed at different times different appearances, but preserving amidst every change a principle of uniform and uninterrupted order, admitting of no deviation, undergoing no disturbance, and presenting no real irregularity." In the views herein set forth there is then nothing new, except perhaps in the

method in which they are set forth. It is one which has occurred to many minds. There is a tendency at the present time to consider disease in its relation to evolution. The papers by Dr. Airy, Dr. Roberts, Surgeon-General Gordon, and Mr. Millican indicate the direction in which this current is setting. The principal zymotic diseases are small-pox, scarlatina, measles, whooping-cough, diphtheria, cholera, and typhoid. We have evidence to support the view that these diseases are caused by micro-organisms. These diseases must be studied in the same way that the naturalist studies animals and plants. The naturalist, when engaged in the study of the life-history of any individual animal or plant, looks in a broad-world point of view at his subject, and by the aid of evolution throws light on the genesis, distribution, development, transmutation, and varieties of each animal and plant. The scientific physician must approach the study of disease in the same way.

The following is an outline of what I believe should be done:—

1. *The Genesis of Contagium Vivum.*—Under this head will be included the life-history of each form, tracing it as far back as possible. Evolution does not tell us when each seed, as, for instance, that of the oak or the ash, first appeared. We can only go as far back as the historical period extends; so we cannot expect to be able to reach the ultimate stage when each disease first appeared. Evolution fixes in what part of the globe each plant examined first appeared, as the scientist not only traces back to the earliest period its existence, but also, by the study of its habits, is able to determine the zone in which it could exist. As regards the genesis of each individual disease germ we must apply the general principles of evolution.

2. *Reproduction.*—Under this head will be considered the mode of reproduction, whether slow or rapid, whether the seeds are derived from seed forms, or whether multiplication takes place by fission. Example: Drs. Dallinger and Drysdale's experiments on the life-history of some monads. These observations are models of what is wanted.

3. *Development, Maturity, and Decay.*—Duration of life in each form of contagium. How long may it be preserved? Average period of existence in mature and embryonic form. Morphology and physiology.

4. *Laws Controlling Contagia, &c.*—Special seasons of activity; the influence of environment on each disease; sanitary conditions and relation to physical phenomena; influence of oxygen in the atmosphere; heredity, variations; crossing or transmutation; susceptibility; relation of the habitat; progressive development of types; application of analogy of laws regulating plant life.

5. *Distribution in its Geographical Relations.*—Influence of climate; atmospheric variations; warmth, moisture, winds, barometric, electric, thermic disturbance, &c. Secondary natural influences; currents; winds; animals, transport by. Effects of human interference. Example: Measles introduced into Fiji Islands. Migrations. Effects of cultivation by civilisation. Effects of extinction of diseases by sanitation, similar to extinction of weeds in the plant world. Distribution of disease in zones. Relation of disease to flora and fauna. Natural selection for localities. Latitudes in which diseases are found. General method of diffusion.

6. *Geological Distribution.*—Nature of soil, subsoil, alluvium, clay, &c.; rock. Mountain, valley, or plain; drainage; swamps; watershed; rivers; lakes.

### GENERAL PREVENTIVE MEASURES.

These can only be secured by establishing, as it were, a sanitary cordon round the world, and by the combined investigation of disease by an international method,—London, Paris, Berlin, Vienna, Brussels, &c., to be in communication, so that the heads of sanitary bureaux in each country may know the sanitary state of each country. This could be done by maps, charts, and records, to be framed and kept on a uniform plan. The incidence of disease in individuals and communities will be noted; sex, age, colour, nationality will have their proper place assigned; sporadic, endemic, and epidemic states will be considered in relation to causation. Hygiene will thus be carried out in a cosmic spirit; all those minor considerations as trades and professions will be examined in their relation to disease; whilst the value of food, pure air, water, &c., will be also appraised.

Vast statistics on almost every point connected with disease will by these means be secured, and conclusions drawn

theretrom. Thus will be obtained the sum of the conditions of the causes and propagation of disease; thus will be found the varying effects of climate and other agencies; and, above all, we shall learn the value of preventive measures necessary for its eradication. We have not as yet in England arrived at an appreciation of some of the simplest elementary truths in reference to prevention; for instance, the notification of infectious diseases and hospital accommodation for them are two of the first essentials. They should be State regulations. Each town is now allowed local option as to what it shall do. It seems Quixotic to attempt a broader scheme in the face of the prevailing indifference or disregard for both these measures in England. Prevention and spread of disease are not only State questions, but they have a cosmopolitan interest. Now that communication between different countries is so rapid and so much facilitated by steam, the health of one country is of vital interest to all countries; causes operating in England may affect France and *vice versa*. For example, let us take the sanitary state of Hull. Hull is a seaport town. Let us look at the sanitary state of this town in the year 1881. In consequence of the prevalence of scarlatina the Local Government Board sent down Dr. Airy to inquire into the sanitary condition of the town. Dr. Airy held the inquiry on the 9th and 10th of March. The medical profession of the town submitted a memorial from which I extract a few items. The memorial sets forth that the outfalls of the sewers are blocked for sixteen hours out of the twenty-four, and that the ventilation of the sewers is most defective. The present mode of collection of night soil is very inefficient, being effected irregularly in open carts. Refuse is deposited in various parts of the town on unused plots of ground. The connexion of houses with the main drainage is notoriously insufficient. New houses are not examined during the course of erection as to their drainage and other sanitary arrangements, and building sites are frequently formed by the filling up of disused brickponds with animal and vegetable refuse and street scrapings. The Artisans and Labourers' Dwellings Act and the Sale of Food and Drugs Act are not properly carried out, nor are the sections of the Public Health Act dealing with offensive trades and the smoke nuisance. A reservoir supplying water to the town is uncovered, though exposed to the foul emanations issuing from fish and bone manure works in close proximity. The hospital accommodation for cases of infectious disease occurring in the town is totally inadequate, especially in view of the special danger to Hull arising from its close and frequent communication with the Continent. Disinfection is not undertaken by the local authorities free of expense, and the charges which the Corporation make no doubt deter many people from having their disinfection properly done. There is no mortuary in the town, and the means adopted for the prevention of epidemics are generally inadequate. This is a sad picture in the nineteenth century. Hull in this insanitary condition is a danger to the world. She may distribute scarlatina by ships as well as wind and wave currents. At present health officers of different countries are ignorant of the general sanitary state of other countries. Under my system the state of Hull would be known. Perhaps a friendly communication might be made by some foreign State to the Minister of Public Health in England to look after the sanitary state of Hull if this international system were at work.

My leading ideas are—1. That the sanitary authorities of each country should work on one uniform plan and under central direction. 2. That all sanitary authorities in every country should interchange maps, &c., and that the methods of recording disease should be the same. It is easy to draw up forms for international use. I have given one quotation from Buckle. I shall conclude with another, as an excuse for not tracing in detail the way in which diseases have originated or spread:—"To do this would require a learning and a reach of thought to which hardly any single man ought to pretend, since it is one thing to have a perception of a large and general truth, and it is another thing to follow out the truth in all its ramifications, and prove it by such evidence as will satisfy ordinary readers"—(vol. i., p. 131).

Hallifax.

THE committee of the Hastings Infirmary have just accepted an offer from the Misses Brisco to present to the trustees the large and commodious White Rock Villa for the purposes of a convalescent home for the infirmary patients.

## SOME OBSERVATIONS ON THE CONTAGIOUS DISEASES ACTS.

By RAWDON MACNAMARA, F.R.C.S.I.,  
SENIOR SURGEON TO THE WESTMORELAND LOCK (GOVERNMENT)  
HOSPITAL, DUBLIN.

OF the many burning questions at present agitating our minds, perhaps there is none discussed with greater warmth than the propriety of retaining amongst our statutes the Acts of Parliament known by the name of the "Contagious Diseases Acts." Whether they should be abolished, retained, or even extended is discussed with an amount of energy approaching acrimony, calculated to excite surprise in the calm mind of a philosopher; and yet it strikes me that in all this controversy the question has been almost exclusively approached by those who would wish, not only their continuance, but their extension, from the man's side of the case, to a very great extent ignoring that of the woman; whilst the opponents of these measures seem to me to think that any beneficial results that may flow from such enactments are confined to the male sex—on their side also ignoring the woman in the discussion. Whilst at once avowing myself as an uncompromising opponent of the "billet de santé" system—an occupation in my opinion degrading to any respectable surgeon—still I should wish to point out, from the woman's standpoint of view, why it is that I should wish these Acts not only to be continued, but to be widely extended; and the facts which I shall submit in support of my views cannot be gainsaid—facts which, if called upon to do so, I can support by unquestionable documentary evidence. During the past five years our return of patients admitted into the Lock Hospital would show an average of 700 unfortunates annually admitted. Of these I am in a position to prove that 511 were reclaimed—something like one out of every seven saved from a life of sin!—225 sent to asylums, 88 reconciled and restored to their parents, 50 sent to the poor-houses, and 148 provided with respectable situations. All this good work due to the fact that their admission into the hospital brought them under the direct pious ministrations of our chaplains, the Rev. Dr. Gibson and the Very Rev. Canon Forde, whose exhortations, ably aided by our Matron, Mrs. Hogan, bore this good fruit. It would be but to abuse the patience of my readers were I to point out how inaccessible to such influences would have been these poor sinners were there no such hospital for their reception; and it is a matter for legitimate speculation how many more might have been rescued were the Acts compulsory, thereby bringing a larger number under such influences.

So far I have been considering the subject from its moral aspect. I should desire now to say a few words upon the physical side of the case. How often have I wished when admitting these unfortunates into my hospital that some of the most earnest of the opponents of the Contagious Diseases Acts could be present to judge for themselves the amount of suffering they would inflict upon an erring sister by permitting her to ply her trade at a period when to do so must have been present torture and future misery. How often has the question been as it were wrenched from me, "My poor girl, why have you not applied ere this?" No one in general practice and unconnected with a Lock hospital can have any idea of the fearful condition in which from time to time patients are admitted into my hospital, which is situated in a city unfortunately not under the Contagious Diseases Acts. Were these Acts in force in Dublin, it would be simply impossible for such harrowing cases to present themselves. As it is, patients rarely present themselves in the earlier stages of their disease, when their treatment is manifestly more amenable. The effect of this on our general population, and more especially upon our garrison, it is unnecessary for me to point out.

Dublin.

PRESENTATION.—Dr. Robert Jones, who has filled the office of Assistant Medical Officer at Earlswood Asylum for two years, and has just been appointed to a similar position at Colney Hatch Asylum, has been presented by the Earlswood staff with a very handsome timepiece and illuminated address as a mark of their high esteem and regard.

ON A CASE OF  
PSORIASIS TREATED BY CHRYSOPHANIC  
ACID INTERNALLY.

BY LEWIS W. MARSHALL, M.D.,  
SURGEON TO THE CHILDREN'S HOSPITAL, NOTTINGHAM.

THE following case is of interest in connexion with others published by Dr. Napier in THE LANCET of May 20th, because, while I endeavoured to act rigidly up to the rules laid down for the administration of chrysophanic acid internally by the author of the paper referred to, the result was not so favourable as could have been wished.

Sarah A. C—, aged thirteen years, was admitted to the Children's Hospital, Nottingham, on May 24th, 1882, having numbers of patches of psoriasis all over her trunk and upper and lower extremities, those on the legs being most numerous and the largest. They existed chiefly on the extensor surface of the arms and legs. She gave a history of having suffered from the rash for six months, when it appeared in small spots, gradually enlarging and becoming scaly. On the day of admission she was ordered the following diet and treatment:—One-third of a grain of chrysophanic acid, with a sufficient quantity of sugar of milk, three times a day, this powder to be used after a meal, and to be continued unless diarrhoea or vomiting ensued. Diet to consist of meat, and avoidance of farinaceous products.

May 25th: Vomited directly after powder last night (5 P.M.), when they were stopped, but resumed at 11 A.M. to-day.—26th: Vomited again last night; no pain or discomfort.—31st: Dose increased to half a grain three times daily; spots fading slightly.

June 5th: Dose increased to one grain.—9th: Vomited after the morning powder.—19th: Dose to be a grain and a quarter.—28th: Two-grain doses used; spots on hands less distinct; made out-patient, but to continue treatment.

July 1st: Spots improving, but not markedly so; has vomited twice since she left the hospital.—12th: States to-day that she vomits everything she eats, and the treatment was discontinued.—19th: An ointment of chrysophanic acid with vaseline (twenty grains to the ounce) was used locally, after which rapid improvement was noticed.

Sept. 8th: The patient was discharged well.—29th: To-day I have heard that the spots have not returned.

Nottingham.

A CASE OF COLIC FROM UNUSUAL CAUSE.

BY HERBERT FENTON, L.R.C.P., &c.

ON Saturday, Sept. 16th, I was called to see Mrs. H—, an Anglo-Indian lady whom I had attended in childbirth a month previously, and found her suffering from colicky pain of a particularly violent character, associated with distressing retching and vomiting.

The history the patient gave was that on the previous Thursday, whilst lifting a box, in weight about equal to a scuttle of coals, she felt a sudden sharp pain in the lower part of the stomach. No notice was taken of this at the time, and the usual household occupations were continued until Saturday evening, though not without occasional twinges of pain. Physical examination showed the abdomen dull on percussion in the left iliac region, though there was no definite tumour on palpation. Elsewhere the abdomen was slightly tympanitic. Tenderness was complained of, and the pain was greatly increased by pressure. There were no signs of hernia. The pulse was 60; temperature normal. Tongue coated with a soft creamy but thick white fur, and the bowels had been opened once since the first feeling of pain on the Thursday. An ordinary effervescent mixture, with two drops of prussic acid (Sch.) in each dose, was prescribed, and turpentine supes directed to be applied over the abdomen. No food, except a little milk, to be given. On Sunday morning the symptoms, with the exception of the vomiting, which was slightly relieved, were aggravated. An ounce of castor oil, with forty minims of laudanum, was then given, and the bowels were relieved about eight o'clock the same evening. One of the neighbours who was acting as nurse kindly washed and examined the

motion, and found a splinter of wood two inches in length and about as broad as three matches. At the time of passing the motion most agonising pain was experienced. After the passage of the wood the symptoms were all relieved, but what was described as a raw pain was still felt in the left iliac fossa. One grain of opium was then given every four hours, with a diet of milk and beef-tea. On the Monday there were signs of general peritonitis, which were speedily subdued by the free use of opium, and the patient then rapidly regained her usual health.

Remarks.—This case shows the necessity of carefully examining the motions in every case of intestinal obstruction, and also illustrates how the patient's own account may to a certain extent mislead; the pain experienced on lifting the box being perhaps a coincidence, perhaps due to some displacement of the previously innocuous piece of wood. The wood was probably swallowed with some French beans, which a boy who prepares them is accustomed to slice on the edge of the table, but at what time it was eaten is unknown.

MIDDLESEX HOSPITAL.

SURGICAL CASES.

(Under the care of Mr. A. CLARK.)

THE following cases which have lately been attending in the out-patient room present some features of interest.

CASE 1. *Chancere of Lower Lip, followed by Secondary Symptoms.*—E. B—, aged twenty-two, attended first on Dec. 29th, 1881, complaining of a hard swelling underneath her jaw. It did not take much consideration to decide that this was a glandular enlargement secondary to a sore on the lower lip, and the sore was a typical Hunterian chancre. The patient herself attached but little importance to the sore, which she stated she had had several weeks, but it was the hard increasing swelling which alarmed her. The girl's explanation of the lesion was that in the course of her employment, filling pickle-tins, she had accidentally cut her lip with a sharp edge. She declared she had kissed no one except a young man to whom she was expecting shortly to be married, and who was seen by Mr. Clark, and found to be perfectly healthy. The patient herself had always previously enjoyed good health, and there was no reason to believe that she had knowingly exposed herself to syphilitic infection; her own statement and that of her mother, who accompanied her, were perfectly straightforward. The treatment adopted was a drachm of the solution of perchloride of mercury three times a day, and in a week there was a marked improvement; in three weeks the chancre had all but healed, and the glandular enlargement much reduced, but then a rash appeared and ulcerated throat, and she has gone through the ordinary course of syphilis. Considering herself well on June 8th, when she discontinued her attendance of her own accord, only, however, to return with palmar psoriasis on July 8th, for which iodide of potassium was prescribed, and this she still continues to take.

CASE 2. *Abscess of the Parotid Gland.*—A. G—, aged fifty, first came on May 18th, 1882, with considerable enlargement about the right parotid, which she stated had been coming for several months. It was in the main hard, but there were several soft fluctuating nodules projecting from it; there was some enlargement of the submaxillary lymphatic glands and several carious teeth, but of these the patient did not complain. The diagnosis was between glandular abscess affecting the right parotid and enchondroma of the parotid. A mixture of carbonate of ammonia and chinchona was ordered, and locally an ointment of belladonna and iodide of potassium was applied. For the next two or three weeks the swelling continued to get harder

and larger, and it was not until Aug. 31st that it burst, and then it rapidly disappeared, leaving a small discharging sinus. The patient always declined to have anything done to her teeth.

**CASE 3. Enlarged Glands surrounding the Carotid Artery and simulating Aneurism.**—E. B.—, aged thirty-three, presented herself on June 26th complaining of pain in the left side of her neck, the result of a blow there ten days previously. There was evident enlargement on that side and some induration round the carotid artery, and with each beat of the heart the tumour expanded in every direction; there was no redness of the skin, not much tenderness on ordinary manipulation, and no perceptible difference in the two radial pulses. There was some enlargement of the cervical glands; the diagnosis was between aneurismal dilatation of the carotid and glandular abscess. The former seemed the more likely. A local application of belladonna and iodide of potassium was ordered and a tonic given internally. She was seen again on June 29th, when there was no perceptible difference. On July 6th the objective signs were the same, but the patient complained of more pain, inability to sleep, and an unpleasant pulsation; she was therefore admitted as an in-patient, and a subsequent exploratory incision proved the case to be one of enlarged glands entirely surrounding the artery.

**CASE 4. Deep-seated Abscess in Axilla.**—L. C.—, aged fifty-six, presented herself on April 10th, complaining of intense pain in her right axilla. She attributed it to a twist some three weeks previously, following which the pain began, and had expected it would get better of itself, but it daily increased in severity, and her health was beginning to be affected from want of sleep, so she reluctantly came to the hospital. There was some fulness over and below the pectoralis major, and extreme tenderness both there and in the axilla, but there was no specially tender spot, no redness of the skin, no fluctuation, no history of a rigor, and no glandular enlargement to be felt. It was believed to be a deep-seated abscess, so a long narrow bistoury was carefully introduced, and some laudable pus escaped; the opening was then enlarged by means of dissecting forceps. There was a free discharge; and the next day the patient expressed herself as being quite well; nothing but a sinus remained, which healed by the 27th, and the patient was discharged. She, however, returned on June 15th, with some oedema of the arm, which, under local friction and the administration of quinine and iron, disappeared.

#### STANLEY HOSPITAL, LIVERPOOL.

UNUNITED FRACTURES OF HUMERUS, RADIUS, AND ULNA, SUCCESSFULLY TREATED; REMARKS.

(Under the care of Mr. ROBERT JONES.)

**CASE 1. Ununited Fracture of the Right Radius.**—J. K.—, aged forty, a sailor, fractured his right radius on the way to New Zealand. The captain of the vessel undertook its treatment for the first two months, which consisted in the application of the usual side splints. The patient on landing procured a surgeon, who proclaimed non-union, and persisted in the use of splints for a further period of six weeks. No success, however, accompanied this, and, in J. K.—'s own words, "For four months once a week the doctor took hold of my arm and elbow and shook it for five minutes." The patient subsequently returned to England; and in August, twelve months after his mishap, he was admitted as an out-patient to the Stanley Hospital. The radius was ununited at the junction of the middle with the upper third. Around the fractured ends some thickening was perceptible. He complained of pain at night, more especially when the previous day had witnessed much use of the arm. He was quite unable to do heavy lifting, and any attempt at closing the hand firmly produced "shooting pains" around the elbow. Furthermore, a dependent position of the arm invariably gave rise to an unbearable feeling of fulness at the seat of fracture.

**CASE 2. Ununited Fracture of the Ulna.**—R. S.—, a sailor, aged fifty, became in October last an out-patient at the hospital. On examining him an ununited fracture was found at the middle of the ulna. The ends were freely movable and thickened, and the skin over the seat of fracture much hypertrophied. The subjective symptoms were, pain

at night, loss of power in the limb, and violent neuralgic pains during damp weather. He gave the following history: Twelve months previously he broke his arm in a pugilistic encounter on the plains of the Argentine Republic. It was plastered next day by a practitioner, who advised the removal of the dressing in about a fortnight. This injunction the patient obeyed while at sea, but necessarily with unpleasant results. On his arrival at a foreign port, a doctor applied more plasters and advised more rest. For five weeks this treatment was adopted with no improvement save in the matter of pain. Three months later the patient arrived in England, where he immediately sought advice from a medical gentleman, who proposed cutting down upon the fractured ends and excising them. This procedure he would not submit to.

**CASE 3. Ununited Fracture of the Surgical Neck of the Humerus.**—J. R.—, fifty-six, was admitted an out-patient for fracture of the surgical neck of the humerus. He had met with the mishap the day before, and on his admission the contusion and swelling were so formidable as to render the application of splints quite out of the question; nor were these appearances sufficiently modified to admit of the use of supports until the ninth day, when the arm was immovably fixed. With the exception of the usual weekly trimming, this fixity was undisturbed for seven weeks, at which time there was absolutely no union. Three weeks more of anxious waiting and withal no change.

**Remarks by Mr. JONES.**—In the treatment of these cases I followed the method introduced to the profession by Mr. H. O. Thomas—that known as "percussion." Of this there are two varieties. The one consisting in severely percussing the limb over the seat of fracture at long intervals; the other in its daily but gentle performance. Whichever plan be adopted elastic bands should also be tied above and below the fracture to induce local congestion and thereby facilitate the reparative process. More especially is this necessary at night time, when the circulatory system is less active than during the day. The hammerlog is performed with an instrument covered by an indiarubber cap, so as not to lacerate the soft structures. In its absence, however, anything almost will suffice. In Case 1, the bone being somewhat deep seated, I adopted the method of severe hammering, which I performed once a week. The patient tolerated it very well and complained but little of the pain, although the indiarubber tubes tied round his arm at night made him very restless. I applied no splints, but merely permitted the carriage of his arm slung in hammock-like fashion. This lasted five weeks. After each beating a good deal of swelling and even some contusion marked the occasion. At the end of the fifth week, having noticed a decided thickening of the ends of the bone, I applied splints for four weeks, removing them in time to find union complete. Case 2 is more interesting because more rare. In treating the patient I dispensed with the elastic tubes, and the bone being superficial it was, of course, better to try the gentle mode of percussion than that adopted in Case 1. Accordingly I hammered twice a week and kept the splints firmly applied. In a little over four weeks union was firmly established. In both these cases the treatment gave the patients hardly—if indeed any—more inconvenience than they had already endured. Case 3 differs from the others in being a less confirmed non-union. The patient was ten weeks in splints after a primary delay of nine days; and it is impossible to say but that another month's continuance would have produced union. I thought it best, however, not to trust to this alternative, and, using my fist for a hammer, I worked away twice a week for nearly two months, with completely satisfactory results. I may mention that the elastic tubes may be applied immediately after the gentle method, but it is best after the severe mode to wait until the local irritation commences to subside, and thereby prolong it. Should the contusion be very marked, it would, of course, be unwise to apply them at all. As a matter of detail, I may add that the tubing should not always be tied to the same spot, or else ulceration may result. Generally speaking its application at night-time is quite sufficient, and affords the arm very acceptable respite during the day.

THE New Orleans City Lunatic Asylum has been abolished and its inmates transferred to another institution. This step, it is stated, has been taken in consequence of the exposure by a novelist, Mr. G. W. Cable, of serious abuses in the asylum.

## Medical Societies.

### ROYAL MEDICAL & CHIRURGICAL SOCIETY.

*Dislocation of the Foot, with Version and Torsion of the Astragalus. — Ophthalmoplegia Externa, complicating Graves's Disease.*

THE first meeting of this Society after the vacation took place on the 24th inst., Mr. John Marshall, F.R.S., President, in the chair. At the commencement of the business of the evening, the President directed the attention of the Fellows present to certain proposed alterations in procedure initiated by the Council, comprising increased facilities for the discussion and reading of papers, the insertion of debates in the Proceedings and the exhibition at the meetings of scientific inventions, anatomical and pathological preparations, &c.

Mr. RICHARD BARWELL read a paper on Dislocation of the Foot with Version and Torsion of the Astragalus, of which the following is an abstract. Dislocation of the astragalus is not uncommon, the bone, displaced from the socket formed by the leg-bones as well as from the rest of the tarsus, receiving, in nearly all instances, a twist, so that its surfaces look in abnormal directions. Another very rare form of injury is that of which the following is an example: G. F—, aged twenty-eight, received the injury by the overturning of a gig that he was driving, he falling on the right foot. The foot was greatly inverted, the heel raised; the inner malleolus was much obscured, the outer very prominent. The round head of the astragalus was in front of and below the external malleolus. Running from the head to the upper part of that malleolus was a ridge of bone convex outward. A small wound a little way up the leg communicated with the seat of injury. Attempts at reduction, even though the Achilles tendon was divided, were ineffectual. Mr. Barwell excised the astragalus. It was in its normal place in the tibio-peroneal socket, but was twisted, so that the trochlea looked outward, and rested against the articulating face of the outer malleolus. The man did extremely well; he was discharged in three months, walking with crutches, and was shown at the Society's meeting, walking well without any assistance from crutch or stick. After a few remarks on the difficulty of nomenclature in dislocation about the tarsus, the author referred to Malgaigne's description of version and torsion "*sur place*," the former referring to a turn of the astragalus on its perpendicular axis. Of these Malgaigne gives four examples, and the author had collected two others. They all, with one exception, were inward. Torsion, by which he means a twist on the antero-posterior aspect, is in reality more rare, although it would appear on first sight more common because Malgaigne quotes six cases; but on examination of the original records, these changes he found to be not *sur place* save in one case, Dupuytren's—and even here the bone was nearly extruded—and one preparation, the history of which is unknown, and in which the turn is very slight. The author's case is the only one in which a diagnosis has been arrived at during life, and, as far as can be ascertained, the only one in which the bone turned a quarter of the circle, and lay fairly in the tibio-peroneal socket. An appendix was added giving a short description of every case both of torsion and version in corroboration of these statements.—Mr. SPENCER WATSON, after remarking upon the rarity of dislocations of the astragalus, referred to the case of a girl who sustained a compound dislocation of the bone outwards, necessitating its excision. The result of the operation was very satisfactory, for having seen the patient a few years afterwards he found that there was free movement at the ankle and a normal appearance of the foot. Such a result was encouraging for the ultimate issue of Mr. Barwell's case.—Mr. BARWELL explained the grounds upon which he arrived at a diagnosis in his case—viz., the projection outwards of the convexity of the trochlear surface of the astragalus. He exhibited a preparation of a foot after excision of the astragalus, showing bony union of the os calcis, scaphoid, and tibia—and believed this always took place—the subsequent mobility occurring at the tarsal joints in these cases, and not at the ankle. He referred to the fact that Malgaigne had misread some of the descriptions of astragalus dislocation, and stated

that he excised the bone in preference to attempting its reduction, because it was detached from all sources of its nutrient supply.—The PRESIDENT confirmed Mr. Barwell's statement as to the discrepancies arising from imperfect descriptions of such injuries, and pointed out that the astragalus differs from all the other tarsal bones in having no tendon inserted into it. Its main connexion was with the broad astragalo-calcaneal ligament, which must be torn through in the dislocation, thus seriously damaging the vitality of the bone, and leaving the surgeon no alternative but its speedy removal.

Dr. FRANCIS WARNER then read a paper on Ophthalmoplegia Externa complicating a case of Graves's Disease. The patient was a woman twenty-five years of age, and was the subject of Graves's disease of four years' standing. There was marked mental excitability, and she was frequently attacked with gastric crises, vomiting, dyspnoea, and palpitation. Both eyes were nearly immobile, a condition not accounted for by proptosis; this had existed five months before admission into hospital. Limitation of movements was not equal in the two eyes, and was greater in the horizontal than in the vertical directions; double ptosis was marked. There was also bilateral paresis of the seventh and fifth pairs of nerves, and marked tremor of the legs. There appeared to be no evidence of syphilis. Under treatment the goitre subsided, and the general condition greatly improved, but the ophthalmoplegia remains. The unequal amount of paralysis of the two eyes is taken as some evidence of an independent nerve-centre for the movements of either eye, and this is supported by observations in infants in deep sleep and adults in coma, when either eye may be seen to move separately and independently. Again, the greater limitation of movement in the horizontal as compared with the vertical direction is pointed out as probable evidence that separate centres govern these movements respectively.—Mr. POWER pointed out the reasons in favour of regarding Graves's disease as dependent on lesion of the cervical sympathetic, especially the cardiac and the gastro-intestinal derangements. In Dr. Warner's case the protrusion of the eyeball alone was not sufficient to account for its impaired movements, and there was evidently independent oculo-motor paralysis. Corneal ulceration was very rare in Graves's disease, and he attributed it in this case to inability to move the eyeball upwards beneath the lids. In this case there were evidently cerebral lesions superadded to those of Graves's disease.—Dr. ALTHAUS had never met with the association of Graves's disease and ophthalmoplegia. Although the symptoms of Graves's disease point to lesion of the cervical sympathetic, yet in many carefully recorded cases no such lesion had been found. Syphilis was the almost invariable cause of ophthalmoplegia, whether internal or external. Speaking of Mr. Hutchinson's view as to the localisation of lesion of the lenticular ganglion in internal ophthalmoplegia, and of the nucleus of the third nerve in the aqueduct of Sylvius in external oculo-motor paralysis. Dr. Althaus remarked that recent observations (pathological and experimental) in Germany pointed to the existence of centres governing the iris and ciliary muscle in close proximity to the third nerve nucleus. Again syphilitic lesions were often widespread (e.g., ophthalmoplegia might complicate locomotor ataxy) and it was conceivable that both the centre mentioned and the cervical sympathetic were involved in this case. He also referred to the persistence of ophthalmoplegia and its intractability, as well as liability to relapse, although some amelioration may be produced by large doses of iodide of potassium.—Dr. SAVAGE had seen many cases of Graves's disease in the insane, but never associated with ophthalmoplegia. In two cases examined post mortem he had failed to find any lesion of the sympathetic; but in one there was disorganisation of the suprarenal bodies. Although Graves's disease was a nervous disease, it exhibited three or four different conditions, and was met with in general paralysis of the insane as well as with other derangements.—Dr. B. O'CONNOR said that in some of Graves's earlier cases the thyroid enlargement was temporary, and in one case a peculiar form of dyspnoea was attributed to temporary dilatation of the aorta pressing on the trachea. He suggested that the cardiac ganglia might be the seat of lesion. In later cases described by Graves, the goitre was more permanent, and a marked difference was observed between the carotid and radial pulse.—Dr. WARNER, in reply, pointed out the large area involved in this patient, there being paralysis of the fifth and seventh nerves as well as of the third, and the tremor of the feet indicated some

change in the spinal cord. There was no evidence at all of syphilis; and the corneal ulcer was purely local, and probably due to the lesion of the fifth nerve. Mercurial treatment has been tried but abandoned; and the diminution in the thyroid swelling followed the application of cold by Leiter's tubes. This improvement under cold suggested sympathetic disorder, the ophthalmoplegia remaining.

At the close of the meeting the President directed attention to two scientific instruments upon the table. One was an apparatus designed by Mr. Robson of Leeds, for the purpose of producing a dry antiseptic vapour. It consisted of two metal U-shaped tubes in connexion with a foot-bellows, one tube being filled with cotton wool to filter the air, and the other with pumice to receive the antiseptic fluid—e.g., eucalyptol. The apparatus had been used in cases of ovariotomy, and it was intended to replace the spray. The other instrument was the ingenious metallic clinical thermometer originally shown to the Medical Congress last year by Messrs. Mayer and Meltzer, who had since perfected it. It is constructed on the principle of a Bourdon tube, which is filled with a highly expansive fluid, and which in expanding moves a pointer set on a dial by means of a rack and pinion.

### MEDICAL SOCIETY OF LONDON.

#### *Cranial Osteophytes in Congenital Syphilis.—Gastrostomy.—Inflammation, Suppuration, and Ulceration of Tongue.*

At the meeting of this Society on the 23rd inst., Mr. F. Mason, President, in the chair,—

Dr. RADCLIFFE CROCKER showed the Skull-cap of a child aged a year and ten months, with well-marked Osteophytes from Congenital Syphilis. The living case was shown last year with extreme anæmia, enlarged spleen, and cranial thickenings, but with no other signs of syphilis. The family history of miscarriages, and early deaths was corroborative. The child died from bronchitis. The thickenings were well marked over the frontal and parietal eminences, and on each side of the sagittal suture posteriorly. The borders of the anterior fontanelle were quite thin. The rough drab-coloured surface of the new bone was in marked contrast to the smooth, white, healthy bone.—The PRESIDENT thought there was very little evidence of congenital syphilis in the case; and Dr. CROCKER said that he relied on the anæmia and enlargement of spleen for his diagnosis, which was confirmed by the existence of the cranial osteophytes.

The PRESIDENT related the particulars of a case in which he had performed the first stage of Gastrostomy. The patient was a man aged sixty, who had carcinoma of the left tonsil, which was growing so rapidly as to interfere with deglutition and respiration to a dangerous degree. The general details of the case had already appeared in THE LANCET of Oct. 14th; the specimen showed the kind of union that had taken place between the parietal layer of the peritoneum and the visceral layer of the stomach, an amount of union not sufficiently strong to justify opening the cavity of the stomach. Had life been prolonged a few days the union would probably have been thoroughly solid. Death took place on the third day after the operation, partly it was thought from exhaustion, but directly from a sharp attack of dyspnoea, for which tracheotomy was performed with temporary relief only.—Mr. BRYANT said it was important to determine when the second part of the operation—viz., the perforation of the stomach—should be performed. The parietal peritoneum should be included in the stitches, of which six or eight should be put in close together. Four should be stout, the rest fine ones. His own experience was too small to accurately fix the date for opening the viscera. In one successful case of his, vomiting displaced the adhesions and one of the stitches before the incision was made into the stomach; he therefore delayed the second part of the operation. In some cases the stomach may be opened on the third day, but if the adhesions are not firm it should be left till the fifth or eighth. In a case of ovariotomy performed by him fifteen or twenty years ago, treated with the clamp, death having occurred on the third day from bronchitis, the abdominal cavity was found to be already closed by adhesions from the external wound.—Mr. GOULD had had lately two cases of gastrostomy. In the first the stomach was opened on the third day with difficulty, for the mucous membrane was corrugated and separated from the muscular and serous coats. The tenotome had to be introduced quite up to the hilt before performing it. Death

occurred from peritonitis forty-eight hours after; the adhesions were extremely slight. The patient was in a state of extreme starvation. He expected to find the stomach thinned; and he had therefore been led to make the stitches too shallow. In the second case the dyspnoea was first relieved by tracheotomy. The stomach was opened on the eighth day after the first part of the operation, and food was introduced several times a day. Peritonitis set in two days after, and death took place on the fifth day. The adhesions were firm, and the cause of the peritonitis was not apparent. Perhaps the injections of food were too large and too frequent.—Mr. E. OWEN preferred Mr. Mason's course of waiting and performing gastrostomy when necessary to that of excising the tonsils.—Dr. HEYWOOD SMITH asked how the antiseptics were managed, and spoke of the value of the eucalyptol spray in abdominal operations.—Mr. BRYANT had introduced his plan of the two stitches to obviate the difficulty met with in Mr. Gould's case. Much care should be exercised in feeding, and for the first few days only warm milk should be given in small quantities.—The PRESIDENT, in reply, said that he had no experience of the eucalyptol spray; his patient suffered from carbolic poisoning, though the exposed surface was so small. The spray was used throughout the operation. As regards the number of stitches, he thought four were enough, and in this case they were closely set. In the future he should use two needles—a surgical needle to go through the abdominal walls, and an ordinary sewing needle to perforate the stomach.

Mr. BRYANT read a paper on some Cases of Inflammation, Suppuration, and Ulceration of the Tongue. He detailed examples of abscess due to injury as well as to idiopathic causes, and showed how this affection has a tendency to get well, and more particularly after an early puncture. He recorded two examples of hydatid of the tongue. The subject of chronic superficial glossitis then received attention, and it was illustrated by cases as well as by a preparation. Superficial ulcerations were then described, and some good examples quoted of the simple dyspeptic ulcer. Ulcers due to local irritation were then described, and cases quoted, in one of which the ulcer had existed for two years, and had been mistaken for a cancer. Deep-seated ulcerations were fully considered, and the differences between the syphilitic, epitheliomatous, and tubercular forms dwelt upon. The tendency for the chronic syphilitic disease of a tongue to pass into cancer was emphasised, and the danger of not recognising the tendency to the full pointed out. The connexion between epithelial cancer of the tongue and ichthyosis was demonstrated, and the local character of the cancer noticed. The necessity for the early removal of a cancerous tongue was strongly enunciated, and some good cases quoted in which a long immunity from the disease, if not a cure, had been obtained. The different modes of operation were then discussed, and statistics given of operations, in which the mortality as a whole from the operation was shown to be about 10 per cent. Amongst the advantages of the operation was advanced the fact that when a cure does not take place great comfort is given, and that a return of the disease is more likely to occur in the glands of the neck than in the tongue itself. Time not permitting of some remarks being made on tubercular disease of the tongue, it was deferred to another occasion. The paper was illustrated by drawings and preparations.—The PRESIDENT said that in his experience patients seldom survived more than two years after removal of the tongue. Cases of abscess and hydatid of the tongue are rare, and so are cases of cancer in persons under forty. He had operated in a case of cancer of the tongue in a lady thirty-three years of age.—Dr. ROGERS asked why Mr. Bryant had given up the use of the galvanic écraseur.—Mr. HUTCHINSON had had similarly favourable experience in operations for the removal of the tongue in cancer. In very few cases was a second operation on the tongue required. Of course the disease returned very frequently in the lymphatic glands. He agreed with Mr. Bryant that the galvanic écraseur was a suitable and convenient instrument, but preferred the wire écraseur because (1) of less liability to secondary hæmorrhage, and (2) the wound takes on a more healthy action after the cold écraseur.—Mr. H. MORRIS spoke of the importance of Mr. Bryant's statements as to the frequency of lung complications in cases not operated on as well as in cases operated on. Two of his own cases related in his paper last session had now lived over two years after the operation. He did not recommend ligaturing the lingual artery in excising, as hæmorrhage was so easily controlled; but in a case of cancerous

hæmorrhage from the mouth he had ligatured both facial and lingual arteries (the former to avoid risk of secondary hæmorrhage) with good result, hæmorrhage ceasing, and the patient living for two years after. At the post-mortem examination the usual foul, sloughy condition of mouth was wanting. He asked if Mr. Bryant considered that abscesses of the tongue always healed readily. In one case he was surprised at the rapid healing of an abscess.—Mr. WALSHAM had also observed rapid healing of lingual abscess. He alluded to the advantage of the cord compressor in removal of the tongue in preventing secondary hæmorrhage and obviating shock.—Mr. BRYANT, in reply, was himself surprised at the favourable results of his statistics of removal of the tongue. He strongly believed in cancer being local at the outset. He was not quite satisfied of the superiority of the ordinary *écraseur* over the galvanic, and did not recall many cases of secondary hæmorrhage after the use of the latter. In one case this was due to the haste needed in operating. In using the cord it had once snapped during the operation, and he preferred a wire to a chain. Mr. Morris's allusion to ligation of the lingual artery was valuable, and he agreed with Mr. Hutchinson as to the infrequency of local recurrence. In one case he removed what was thought to be a recurrent mass a year after excision of the tongue. The patient had lived three years and a half since without further recurrence.

### OBSTETRICAL SOCIETY OF LONDON.

A MEETING of this Society was held on Wednesday, Oct. 4th, Dr. Matthews Duncan, President, in the chair.

*Spurious Hermaphrodite*.—Dr. FANCOURT BARNES showed a child (living) which presented malformations such as those classified by Sir James Simpson under the title of "spurious hermaphroditism." He could find no trace either of testes or of uterus, but thought the child most likely a male.—Dr. CHAMPNEYS had, in a somewhat similar case, detected the uterus by examination per rectum.—Dr. SWAYNE said that there was a specimen in the Museum at Bristol in which the external parts were like those in this case, but the internal organs those of a female.

*Hypertrophy of Placenta*.—Dr. HERMAN showed a specimen of hypertrophy of the placenta. It had been removed piecemeal, and a large part left at the patient's house. The portion exhibited weighed more than four pounds. To the naked eye its structure did not differ from that of normal placenta. The child was decomposed when born.—Dr. ROBT. BARNES had observed in some cases of hypertrophy of the placenta, dropsy of the placenta, and ascites and anasarca of mother and foetus. Possibly the placental villi were overdeveloped in order to find enough pabulum in the hydræmic blood.

*Degeneration of Placenta*.—Dr. CHAMPNEYS showed (for Dr. Murray) a placenta exhibiting fibrinous degeneration in the uterine and calcareous degeneration on the foetal surface. The child was born alive.

*On an Obliquely Contracted Pelvis of Unilateral Synostosis*.—Dr. CHAMPNEYS read a paper on this subject. The pelvis was that of a child, aged between seven and fifteen, in which the changes at puberty had already slightly commenced. At this point the left sacro-iliac joint became inflamed, leading to synostosis of part of the articular surface. The left half of the sacrum was dwarfed, and this bone rotated so as to look somewhat to the left. The left half of the pelvis was narrowed, the pubic symphysis driven to the right, and its left half displaced behind the right. But compared with most Naegle pelvises, the outline of the brim was less straight, there was less verticality of the ilium than usual, and there was no evidence of transverse rotation of the left os innominatum on its acetabular axis. The author considered the specimen one of a half developed obliquely contracted pelvis of unilateral synostosis, most instructive in its bearing on the production of the typical pelvis of Naegle.—Mr. GRIFFITH thought that the synostosis was congenital. If so, Dr. Champneys' theory would require modification.—Dr. CHAMPNEYS thought the joint showed clear evidence of disease.

*Transverse Septum in the Vagina*.—Dr. GERVIS described a case of the above malformation. The patient was aged twenty-two, and menstruated regularly. She sought advice on account of pain in micturition, due to a urethral

caruncle. About an inch and a half or two inches from its orifice the vagina seemed to end in a cul-de-sac, having on either side a pouch, giving at first the impression that there was a double vagina. In the left cornu was a small opening admitting a probe into the space beyond. The hymen was present. The uterus could be felt per rectum. The septum was divided with the thermo-cautery, giving exit to a quantity of brownish mucus. A granular erosion surrounded the os uteri. The caruncle was at the same time removed. The patient did well, and the endocervicitis began immediately to improve when freed from the apposition of retained secretions. The author remarked on the value of the thermo-cautery in lessening the risk of septic infection in such cases.

*Case of so-called Imperforate Hymen*.—A paper on this subject, by Dr. MATTHEWS DUNCAN, was read. He was induced to relate the case by three circumstances. 1. There was a remarkable absence of any kind of suffering during nearly the whole time of the development of the disease. The patient had never menstruated nor suffered from any uneasiness in connexion with that function until eight months before admission, when she was told by a medical man that she had a lump in the lower belly. Since then she had suffered from irregular aching. The author thought the probable explanation of this was that the uterine body was not distended, for facts showed that dilatation of the uterine body was more difficult and painful than dilatation of the vagina and uterine cervix. 2. The case illustrated the treatment without any injections, which had been the subject of remarks at a recent meeting of the Society. An incision was made by Paquelin's cautery knife. About twenty-five ounces of the usual treacly fluid escaped, about twenty ounces on the following day, and the last of it on the fifth day, in all about fifty ounces. At no time had it any fætor. No hypogastric pressure or interference with the flow was permitted. A piece of carbolised lint was put to the vulva. The patient made an uninterrupted recovery. He thought the risk of peritonitis was increased by the washing out sometimes practised. He thought the cautery knife was preferable to any other mode of making the incision, because its wound was not an absorbing surface. 3. The condition of the pudendum, rendering the term "imperforate hymen" erroneous and misleading. The vagina was closed by a membrane upon which the hymen could be seen entire and healthy, and after the operation the hymen could be seen to have its normal position and relations. He had made the same observation in other cases, and he had seen the hymen present when vagina and uterus were both absent. On these grounds he regarded the view of M. Budin (that the hymen was nothing but the anterior extremity of the vagina) as incorrect.—Dr. ROBERT BARNES said that in these cases toxæmia arose before the blood was evacuated, from decomposition of the hæmato-globulin in the retained fluid. He had not used injections; they were not called for in all cases.—Dr. GERVIS could hardly accept Dr. Duncan's view, that the membrane occupying the area within the hymen was vaginal wall. He thought the variations in shape of the hymen, and the absence of muscular fibres in it, militated against M. Budin's view.—Dr. CARTER had had under his care a case similar to that described by Dr. Gervis. He had divided the septum and the patient did well. He thought washing out was troublesome unless the discharge was offensive or there were symptoms of septicæmia.—Dr. ROGERS mentioned a case under his own care. Some pyrexia followed the operation. The vagina was not washed out till a week after the operation, and when this had been done the pyrexia subsided.—Dr. GALABIN thought it an important question whether in these cases it was desirable to use injections immediately after an interval or not at all. The danger was greater the higher the atresia was situated. He had known of two cases of high obstruction, in which death had followed evacuation, although no syringing was used. Emmett had published a number of cases, many of them of atresia high up, in which recovery had followed treatment by injections. He generally let the fluid flow for twenty-four hours, and then began antiseptic injections. All his cases so treated had been successful. Perhaps it would be best if a perfectly aseptic condition could be maintained by antiseptic dressings.—The PRESIDENT said that Dohrn had entered elaborately into the developmental histories of vaginal closures. What he (Dr. Duncan) wished to show was that cases with blue, thin-walled bulging between the labia were generally, often erroneously, called imperforate

hymen, whereas in many, and also in cases where there was no vagina, a hymen could be distinctly seen.

*New Intra-uterine Stem Pessary.*—Dr. SWAYNE showed a new form of stem pessary. It consisted of a perforated vulcanite stem, which rested on an indiarubber band attached to a modification of Greenhalgh's pessary. These were introduced separately, but when *in situ* united by a silk thread. The advantages he claimed for it were that it was easily introduced, kept in place, and allowed uterine mobility, so that it was free from some of the dangers that attend stem pessaries. He should only use stem pessaries when simpler and safer means of treating uterine flexion had failed.—Dr. HEYWOOD SMITH asked what advantages Dr. Swayne's pessary had over that of Dr. Wynn Williams?—Dr. EDIS thought stem pessaries very dangerous. The position of the uterus was too much regarded, whereas its condition was the chief thing. Numbers of cases of pelvic peritonitis occurred from the injudicious employment of stem pessaries, producing much suffering and not infrequently death.—Dr. ROGERS did not think Dr. Swayne's instrument more perfect than that of Dr. Wynn Williams.—The PRESIDENT did not use any kind of stem pessary. He had known of many deaths from them, but he never knew of a case of version or flexion cured by them.—Dr. ROBERT BARNES thought stem pessaries necessary in some cases. Accidents had occurred from them, but now more scientific instruments had been contrived. He preferred that of Dr. Greenhalgh. He had cured cases of antelexion with stem pessaries.—Dr. HERMAN had known of a death following the use of one of Greenhalgh's stem pessaries.—Dr. SWAYNE said that in his pessary the indiarubber supporting the stem was firmer than in that of Dr. Wynn Williams. He had used it many times, always with good results. He had always carefully watched the patient, and withdrawn the stem whenever it gave rise to pain or rise of temperature.

#### EPIDEMIOLOGICAL SOCIETY.

THE thirty-second session of the Epidemiological Society was opened on the 18th inst. by a conversazione given by Dr. George Buchanan, F.R.S., to members and friends of the Society, at University College, Gower-street. Among the distinguished company present were the Directors of the Army and Naval Medical Services, and other eminent members of the profession. Several microscopical specimens, illustrating subjects with the study of which the Society is specially concerned, were shown during the meeting. Among them, preparations of the ova and living ciliated embryos of *Bilharzia hæmatobia*, exhibited by Dr. Cobbold attracted special attention. The embryos were seen making vigorous movements within the firm outer shell of the ovum, which finally ruptured and allowed them to escape. The specimens were obtained from the urine of a patient who had contracted endemic hæmatobia while in Egypt. Dr. Klein also demonstrated specimens of bacillus tuberculosis in the sputum and lung from tuberculous patients, from the lung of a cow suffering from bovine tuberculosis (*Perlaucht*), of the bacilli of anthrax and septicæmia, of the bacilli met with in the Welbeck and Nottingham cases of ham-poisoning, and the micrococci present in the lymphatics in ovine variola, and in the blood and liver of patients suffering from infantile diarrhoea. A section through the tongue from a case of *Actinomyces bovis* also showed very beautifully the stellate masses of fungus, surrounded by a deeply-stained layer of inflammatory exudation, containing numerous leucocytes. Specimens of the embryo filaria sanguinis hominis from the blood of a patient suffering from chyluria, and from the Chinese mosquito, were exhibited by Dr. Stephen Mackenzie. Examples of trichina spiralis in the muscles of a wild boar, of dracunculæ embryos, of the micrococci of diphtheria, septicæmia, pyæmia, and ulcerative endocarditis, and of the ringworm fungus (*trichophyton tonsurans*) artificially cultivated were also shown by Drs. Easton, Gibbes, Henderson, Mackenzie, and Mr. Malcolm Morris.

The first ordinary meeting of the Society will be held at University College on Nov. 1st, when a paper will be read by Dr. Norman Chevers, C.I.E., "On the Sanitary Defects of the Site of London and its Suburbs."

#### WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

THE first meeting of this Society was held on Friday, October 6th, at the West London Hospital, Hammersmith. The President, Dr. Hart Vinen, was in the chair, and over eighty-three gentlemen were present.

The PRESIDENT delivered an inaugural address, in which he thanked the members for the honour they had conferred upon him by electing him their first President, and congratulated them on the large number of practitioners who had already joined their ranks, which augured favourably for the future progress of the Society. After alluding to the numerous Societies which exist for the prosecution of scientific pursuits, and the value of their labours to the general welfare of mankind, he urged the members to look to science as the best aid to the successful practice of their profession, and as not without its moral results. "For if the suggestion of Newton, that in proportion as natural philosophy is improved in its various branches, the bounds of moral philosophy will be enlarged also—if this be true, as it undoubtedly is, we may point to the labours of our scientific men as not only serving to extend the boundaries of our intellectual horizon, but as exercising a refining and humanising influence over man's moral nature. But there is another light in which we may regard such societies as this, I mean their social aspects. The daily routine of professional duties too often restricts medical men to a very limited orbit, and furnishes them with few occasions for friendly intercourse with their brother practitioners. Here they have opportunities of meeting periodically on common ground, of exchanging opinions on professional and other topics, and by other men's experience enlarging and correcting their own. No remedy is so effectual for healing professional animosities as frequent intercommunication; and if I were asked to prescribe a panacea for their prevention, I should recommend an occasional dinner at the Star and Garter. Some may think this view of the matter savours too much of the sensual, but the periodical recurrence of such a social reunion would, perhaps, be more productive of good results than the strictest code of medical ethics." Dr. Vinen then alluded to the fact that more than twenty years had elapsed since he had filled the presidential chair of another medical society, and referred briefly to the most prominent changes which had taken place during the interval, especially dwelling on the germ theory of disease, which recent researches had done so much to establish, and the benefits which resulted to public health from the advance of sanitary science, in which he claimed for the medical profession the honour of being the foremost workers.

Dr. BURNEY YEO then delivered the address, which was published *in extenso* on October 14th.—Dr. THUDICHUM said he was much interested in Dr. Yeo's paper, though he did not agree with him. There was no proof that the bacteria were destroyed by his process. Those who had examined the expectoration of a phthisical patient and observed the bacilli present in it must have been impressed with the awful nature of the disease; the incalculable number present in the organ seemed to him to render the question of total destruction mathematically impossible. Dr. Yeo admitted that advanced cases were not suitable for this treatment, but he thought that there was no specific which did not cover all cases. He would ask how could these antiseptic inhalations reach the brain, or heart, or any other organ (except the lungs) which might happen to be the seat of tubercular disease?—Dr. ALDERSON thought that great benefit was to be derived from the use of the respirators, and was most certainly ready on this, as on other points, to reiterate the President's cry for "More light."—Dr. RAYNER also endorsed Dr. Yeo's theory.—Dr. BROWNE wished to know how long it was necessary to wear the respirator at a time.—Mr. JACK was of opinion that whether the bacilli were destroyed or not, the process, in whichever form adopted, put the patient into a condition calculated to prevent a nidus being formed for the bacilli.—Dr. THOROWGOOD had no great experience on the subject, but he had most certainly noticed great improvement in those cases which he had so treated. He was accustomed to order the respirator to be worn for an hour in the morning and evening; he found it promoted expectoration. Of the

various antiseptics he himself preferred creasote. Sea air as obtained in a voyage was, too, he thought, most efficacious in the early stages of the disease; later on, it seemed to do more harm than good.—Dr. YEO, in reply, said he did not wish in the remarks he had made to dogmatise in any way, he was only anxious to show that the theory he had been laying before them had a scientific basis. He must say, in answer to Dr. Thudiehum, that he was unaware of his having used the expression "specific"; it was not his custom to use the word, and he failed to see anything detrimental to his theory in the fact that advanced cases were not suited to the treatment. As regards the alarming number of bacilli pictured, he would simply suggest that if Mr. Lister had frightened himself about the number of organisms to be encountered there would never have been any such thing as antiseptic surgery. The advantage of the respirator, as suggested by himself, consisted in its lightness and comfort in wear, in fact to its not being a muzzle; his patients wore theirs as long as possible during the working day, it being only necessary to remove it while eating or drinking. He agreed with Dr. Thorowgood in preferring creasote, but he had used eucalyptus and pine-wood oil with great advantage, though the latter was to some rather irritating. He saw no reason why still more direct treatment should not be attempted, and he hoped soon to try the effect of injecting by the long needle of an aspirator, a small quantity of bichloride of mercury.

Mr. SAVILE KENT and Mr. BAKER showed specimens of Bacilli, Bacteria, &c.

## Reviews and Notices of Books.

*Medical and Surgical Aspects of In-Knee (Genu Valgum); its Relation to Rickets, its Prevention, and its Treatment with and without Surgical Operation.* By W. J. LITTLE, M.D., F.R.C.P.; assisted by E. MUIRHEAD LITTLE, M.R.C.S. Illustrated by upwards of 50 Figures and Diagrams. London: Longmans, Green, and Co. 1882.

THE appearance of this book at a time when surgeons are numbering their osteotomies by the score, and even by the hundred, is very opportune. The authors regard "in-knee" as an affair of the joint, as the deformity to the production of which there is a natural tendency in the articulation, and to which many morbid changes in and around the joint conduce; the insufficient support of the joint by the surrounding muscles being one of the main direct causes of the deformity. They by no means share in the opinion that "in-knee" is in all cases due to rickets. "In the several forms and subforms of genu valgum resulting from different diseased actions, the point on which the progress of distortion may be said mainly to turn is undue contact of the external condyle with the opposing part of the tibia, and consequent arrested development or deterioration of these parts. The identity of distortion and mechanical changes is undoubtedly due to the identity of mechanical acting forces." The pathological views of the authors are briefly expressed in this passage, and they hold that "enlargement of the internal condyle is not pathognomonic of any form of in-knee; that the essentially most damaged parts of the joint are the external condylar part, and the external articular portion of the tibia." As regards treatment, our authors are opposed to much that is now in vogue, and to all that partakes of any roughness or severity. They admit that there are some cases of neglected in-knee in which osteotomy is the only or the best mode of relieving the deformity, and of all the ways of performing this operation for genu valgum they prefer that practised so often and so successfully by Macewen of Glasgow. The authors' treatment aims at correcting the deformity, and preventing its re-formation until the joint surfaces have recovered their proper shape and the muscles and ligaments are able to support the joint. They say: "A long-continued experience has shown that to cure in-knee, besides diet and hygiene, two things are necessary—viz., to keep the knee extended during the treatment by an un-

yielding apparatus, and to employ a similar contrivance to attain adduction of the leg." It is with justice insisted on that this mechanical treatment requires great skill on the part of the surgeon, and demands his personal attention, and should not be left to friends or to the instrument maker. To the neglect of these precautions much of the alleged ill-success of the mechanical treatment has been due, and children who ought to have been rescued by proper management have been sent into life crippled.

*Health Resorts and their Uses. Being Vacation Studies in various Health Resorts.* By I. BURNEY YEO, M.D. Lond. Pp. 316. London: Chapman and Hall. 1882.

THIS work consists chiefly of a reprint of articles which have appeared in *The Times* and *Fortnightly Review*, and may, therefore, be considered as having been intended chiefly as a guide to invalids and others in the selection of suitable health resorts; but it also contains much information which must prove valuable to those members of the profession who have not had the opportunity of personally visiting these places. In an introductory chapter Dr. Yeo discusses at some length the important differences between the action of sea and of mountain air upon the system, and points out in detail their respective properties. He then asks the practical questions, Who should go to the mountains? Who should go to the sea? And who should go to neither? For the answers we must refer our readers to the book itself, where they will find the conditions stated which ought to influence them in deciding this vital point. Of the high mountain resorts, the author gives a very full and interesting description of those in the Upper and Lower Engadine and of Davos Platz, with special reference to the influence of a prolonged residence on cases of incipient consumption. Of Davos Platz he appears to entertain a favourable opinion as far as the climate is concerned, but calls attention to the very serious evils of overcrowding and over-building, which have arisen from its growing popularity, and on that account is disposed to recommend St. Moritz, in the Upper Engadine, as being preferable, except "to the feeble classes of pulmonary invalids who are also the victims of more advanced disease." A short account is given of the principal health resorts of the Pyrenees, and the cases to which they are most likely to prove beneficial, and also of some of the other French watering-places, especially Vichy, Royat les Bains, Mont Dore, and La Bourboule. A chapter is devoted to some of the more important Rhenish spas, with special reference to "their sanitary conditions, and to the provisions which obtain in them for the prevention of the origin and spread of epidemic and contagious diseases," and with a view to provide a detailed professional estimate of their respective merits. The book concludes with a couple of chapters on the important and interesting subject of winter quarters for those who desire to avoid the damp, cold, and variability of our winter climate. Dr. Yeo has gone fully into the characteristics of the climate of Egypt, Mogador, Tangier, Algiers, and the various resorts on the Western Riviera. He has given the climatic, sanitary, and social conditions of these in sufficient detail to enable medical men to select the locality most likely to benefit their patients, and the latter to choose that which is best suited to their habits and tastes. To those members of the profession who are consulted on the subject of health-resorts for the delicate and the diseased, Dr. Yeo's book will afford much useful information in a pleasant, readable form, and may aid them in the selection of the most suitable residence for their patients. We would, in conclusion, only remind them of the importance of impressing upon their patients how much of the benefit to be derived from these resorts depends upon the care they take of themselves, and

the precautions which are necessary on the part of invalids to avoid the dangers, even in these comparatively mild climates, to which they are too apt to expose themselves.

*Quarterly Journal of Microscopical Science.* No. LXXXVIII. Edited by Professors LANKESTER, DYER, and KLEIN. London: J. & A. Churchill. 1882.

THIS part opens with a tribute of regret to Professor Balfour, whose premature death on the Swiss Alps, in July last, must be a subject of deep regret to all who are interested in the advancement of that branch of physiology in which he took so deep an interest—embryology. The University of Cambridge, in recognition of the importance of his subject, had created a professorship in it, and had committed to him the duties of the chair. It will be difficult to find his successor.

Amongst the most important of the papers is one by Dr. Horst on the Development of the European Oyster, a subject of considerable obscurity and very difficult to elucidate, since the embryos not only pass their first stages of development within the pallial cavity of the mother, but the impregnation of the eggs takes place also internally instead of externally, and it is possible that the eggs and the spermatozoa even meet in the efferent ducts of the genital gland. The successive stages have to be followed in a series of animals, since the opening of the oyster by the division of the adductor muscle is fatal to it, and the development of the spat is arrested. The segmentation appears to be the same as that of other Lamellibranchs; it passes through a gastrula stage. The shell gland early appears, and is of great size, arising by an invagination of the epiblast. It is an azygous formation, so that there are not two glands for the two shells. Some good illustrations of the first stages of development in the oyster are given in the plate which accompanies the paper. Mr. H. Marshall Ward gives the result of his researches on the Morphology and Life History of a Tropical Pyrenomycetous Fungus. Mr. Blomfield describes the thread-cells and epidermis of the Myxine; Mr. Hickson describes the eye of the Spondylus, one of the Lamellibranchs. The retina stretches across the eye-cup as a broad band. Mr. Walter Gardiner shows that there is an open communication between the cells in the pulvinus of *Mimosa pudica*; Mr. Haddon gives a short paper on the development of Mollusca, describing the earlier stages; Mr. P. H. Carpenter continues his Notes on the Morphology of the Echinoderms; Professor Lankester describes the vertebration of the tail of Appendicularia; Professor Moseley supplies some notes on the structure of Seriatopora, Pocillopora, and some other corallines, and Dr. Vincent Harris a note on the Pacinian corpuscles.

*Brain.* October, 1882.

THE current number opens with an interesting systematic account of "Alternating Insanity," or "Folie à Double Forme," by Dr. Achille Foville, translated by Dr. Urquhart. Dr. Obersteiner of Vienna describes some additional cases of chronic morphinism with especial reference to the mental changes which result. The pathological physiology of the nervous discharge in convulsions is the subject of some speculations by Dr. Mercier; Dr. Ross contributes several interesting observations of spasmodic paralyses of infancy, and a case of tumour of the brain, causing localised convulsions, is discussed by Dr. Hughlings-Jackson. Among the reviews the most noteworthy is a lively and trenchant criticism of Luys' "Brain and its Functions," by Dr. Bucknill, and amongst the clinical cases an observation by Dr. Ferrier, of the singular condition in which impressions on one-half of the body are referred to the corresponding point on the opposite side, termed by Obersteiner "Allochiria," a condition which is at present a physiological enigma.

## ON ABSORBENT DRESSINGS, ETC.

To the Editor of THE LANCET.

SIR,—I have read with pleasure the article on the above subject, with illustrative cases, by Mr. Berry, in your issue of the 21st inst., and make a few brief notes concerning the cases. In Case 1 I find the good effects of the "dry absorbent dressing" were promoted by a little red lotion (dry?) and boracic lint. Nevertheless, an ulcer, going on to erysipelas, occurred before complete recovery, and the patient had to be removed to another ward, and appropriate treatment was employed. I imagine undue pressure caused the ulcer, and want of antiseptic dressing might be answerable for the erysipelas. In Case 2 carbolic tow (aseptic) was employed, and the case did well. Case 3 seems to have recovered in spite of everything, for the sutures ulcerated out and were replaced by strips of plaster. The flaps swelled in spite of the absorbent dressing evidently, and got well *per vim naturæ*. A week or two after this Mr. Berry performed a similar operation (on a healthy subject), for accident, who died shortly afterwards. This case is not reported. Case 4, Mr. Berry states, had been treated antiseptically previously to his taking charge of it. Now, why should he laugh at antiseptic treatment, and write his letter to you on April 15th, when on May 18th he sponged out an abscess cavity in Case 4 with a solution of carbolic acid? No doubt at the same time he sponged the new wound (through the condyles), and brought the flaps together; the natural glaze of lymph and the dressing over it prevented further access of noxious atmospheric particles to the part. Mr. Berry says he is not particular as to what material his dressings are made, or whether they be aseptic or not. From his cases we at least learn (?) what we knew before, and see once more that antiseptic dressings were followed by the best results in these cases. The fact that Mr. Berry only publishes his favourable cases takes materially from the value of his communication. Though not attached to the infirmary, I had frequent opportunities during the past year of visiting the Wigan institution; seeing many things, saying few, I came to the conclusion that Listerism, or the antiseptic treatment, are terms not fully understood there. An operation is there followed out thus antiseptically, except that—(a) As a rule the part to be operated on is not cleansed with antiseptics previous to operating. (b) The spray is not in working order to begin with, and when the steam is up the vapour plays either under the table or in the operator's face, occasionally perhaps on the wound. (c) The operator's hands are not invariably dipped in antiseptic fluid before operating. (d) The assistants may keep their hands in their pockets until required, and without cleansing them may handle the wound or the instrument, and feel the patient's pulse between whiles. (e) Anyone of the staff (general practitioners in the town) requires no cleansing, because his breath is antiseptic when the spray does not play on the wound, and his hands are invariably considered pure and aseptic. (f) The instruments are not carefully cleansed in antiseptic fluid before use. A pair of forceps used to pick up an artery is put down anywhere, and then used to secure another uncleaned. (g) The spray, exhausted before the operation is over, is not used when changing the dressings. (h) If the operation is not very successful they blame their method. I blame their method—not Lister's.

In the treatment of wounds, whether by Listerism or otherwise, I suppose we are all taught in our hospitals the value of drainage and rest. Concerning pressure, we are usually told it should be gentle and equable. Mr. Berry gives us pressure without any reference to the number of pounds on the square inch, nor whether one part should be pressed more than another. Now for absorbents. The employment of tow is no new thing, nor is the use of cotton-wool, nor lint, nor a strip of worsted, but they are the better for being aseptic. What can be more soothing to the patient than a strip of lint soaked in glycerine and applied to a swollen, painful, and raw wound of a finger?

I am, Sir, yours, &c.,

Brighton, Oct. 21st, 1882.

H. ROGERS-TILLSTONE, M.B.

THE sum of £393 18s. 6d. has been handed over to the treasurer of the Lincoln County Hospital, as the proceeds of the last Hospital Saturday collection.

## THE LANCET.

LONDON: SATURDAY, OCTOBER 28, 1882.

IN a previous article on the report of the Royal Commission appointed to inquire concerning small-pox and fever hospitals, we indicated the principal subjects which had been dealt with. Some of these subjects are of immediate and pressing concern in connexion with the actual prevention of epidemic disease in the metropolis; others deal with matters relating to the history of small-pox in London, to sanitary administration, and to allied topics. The principal interest for the moment centres in the past work of the Metropolitan Asylums Board, and this is entered into in much detail by the Commissioners. The report commences with a history of the constitution of that Board and of the establishment of the five hospitals under its control, together with some account of the proceedings to which the Board have been subjected as regards the Hampstead and Fulham Hospitals. Dealing next with the behaviour of small-pox both in England and the metropolis, it is shown in some valuable tables that, in London especially, whereas this disease had steadily been falling under control up to 1860, it has since then been fitfully but sensibly gaining upon us. Recognising the great source of danger attendant upon the treatment of infectious diseases in ordinary dwelling-houses, and also the fact that much of the spread of small-pox is due to the need of proper means of isolation, the Commissioners urge that the notification of infectious diseases should be made compulsory, and that it should be associated with a power of removal to hospital, not as now merely in the interests of any patient who does not happen to possess proper accommodation so far as his own welfare is concerned, but rather in the interests of the public, who are by reason of his illness exposed to danger. The notification is in the main to be made by the householder, and it is to pass first to the sanitary authority and thence to a metropolitan hospital authority—a method of procedure which will, we fear, lead to the very delay which in such cases it is so important to avoid. It is further suggested that in the matter of the provision of isolation the distinction between the pauper and the non-pauper should be abolished; that all alike who, in the interests of the public, submit themselves to isolation, should be treated at the public cost; and that the hospital authority for the metropolis should be a single body, which in its general aspect ought to be, not a pauper, but a sanitary authority. Coming next to the amount of isolation accommodation needed for small-pox cases in the metropolis, it is, after careful calculation, believed that a permanent provision of some 2100 beds would answer the needed requirements even in years of exceptional prevalence; and it is further stated that, since a large proportion of the milder attacks, as also of the convalescents, could easily be moved outside London, the existing accommodation in the Asylums Board hospitals would suffice, provided it could be used without injustice to the neighbourhoods in which the hospitals are situated.

At this point, however, the Commissioners, before making

any recommendation as to how the needed small-pox hospitals are to be provided, find it necessary to inquire whether such hospitals are or are not centres of infection, and they at once admit that by some means or other the Asylums Board small-pox hospitals have caused an increase of that disease in their neighbourhood. The cases of the Hampstead and the Fulham Hospitals are specially considered, and a well-deserved tribute is paid by the Commissioners to the remarkable report by Mr. W. H. POWER on the influence of the latter hospital. From this report the Commissioners specially quote the proofs, statistical and other, which go to show that in some way the Fulham Hospital, whilst in use for the reception of small-pox patients, did on several occasions most injuriously affect the surrounding neighbourhood. Similar, though less complete, evidence is given as to the influence of the Homerton, Deptford, and Stockwell Hospitals when in use for small-pox. The fact that large small-pox hospitals, containing a considerable proportion of acute cases, are centres of infection, is thus, after full consideration, freely assented to; but the question remains—Are they a source of danger only in their incidents, or are they such *per se*, by disseminating infection through the atmosphere? We have dealt fully with Mr. POWER's views as to this, but we would here further remark that although the "gradation of hospital influence from centre to periphery" might, as the Commissioners point out, result equally whether the influence for harm were brought about by the conveyance of infection by human movements or by atmospheric dissemination, yet the hypothesis of personal communication does not easily explain the following facts: (1) "That the houses on the lines of human intercourse have not suffered more than—or even as much as—other parts of the same neighbourhood"; (2) "the sudden and simultaneous attack of a considerable proportion of susceptible people living round the hospital, and having no discernible relations with the hospital or with each other"; and (3) the striking "constancy in the gradations of incidence upon the several divisions of the special area" round the Fulham Hospital, during five separate and distinct periods when the buildings were in use for small-pox patients. On the other hand, however, all these, in addition to other obscure points, are explicable on the hypothesis of the conveyance of infection through the atmosphere. Indeed, in dealing with this matter we seem to detect a divided opinion on the part of the Commissioners. If they were unanimously of opinion that personal communication by nurses, ambulances, &c., had really led to the spread of disease around Fulham, the recommendations which they make as to small-pox would hardly have been based, as they appear to be, on the operation of an atmospheric dissemination of infection. One proposal as to small-pox is that the number of beds for patients suffering from this disease in any one hospital ought to be limited to "thirty or forty," and it is added that with this limitation "the evil arising from atmospheric diffusion will be reduced within very narrow limits."

With regard to fever hospitals, the Commissioners believe that when well conducted they involve no appreciable risk to the neighbourhoods in which they are situated, and hence they propose that the existing hospitals belonging to the Metropolitan Asylums Board should be retained for the treatment of the infectious fevers other than small-pox, the

fever convalescents being removed to country hospitals. As regards small-pox patients, it is proposed that all the mild cases and all the convalescents should also be removed to hospitals in the country; and, further, that some of the less severe cases should be treated in floating hospitals or in buildings on the banks of the Thames. But they believe that some provision must be made in London itself for the more severe cases, and hence they suggest that on each of the hospital sites belonging to the Metropolitan Asylums Board there should be a detached small-pox hospital for some thirty or forty patients. At first sight, it might appear that under such a course of action our measures of defence against small-pox would turn out to be less effective than those available in the case of other infectious diseases. This, however, is not so. In vaccination we possess a means of prevention against small-pox which as yet has no counterpart as regards any other of the specific fevers; a point fully recognised by the Commissioners, who declare that if careful vaccination were general the liability of the metropolis to serious epidemics of this disease would cease.

Hitherto it has been the practice to use the existing hospitals for patients from any part of the metropolis, an arrangement which has called forth strong protests from the inhabitants of the districts into which outside cases of infection were thus imported. The Commissioners, having regard to the future, condemn this arrangement, for they say, "It is most important to avoid as far as possible the injustice of transferring, in any case, the disease of one populous district to another." And they go on to consider how London may best be divided into hospital districts. That each parish should become a hospital centre, and manage its own affairs as regards isolation, is at once set aside, on the ground that this would necessitate the sudden establishment, on the occasion of every great epidemic, of thirty or forty institutions, some of which would certainly be mismanaged and become effective foci of infection. But it is thought that with a more effective method of election, and with fresh powers as to the purchase and retention of sites, the Metropolitan Asylums Board might be the Isolation Authority for all classes, and that London might under this arrangement be divided into some eight independent hospital districts, each dealing with its own infectious sick, much in the manner already indicated. This arrangement would still leave a considerable aggregation of fever patients at each centre, and it would concentrate together, in a manner heretofore not contemplated, a number of the more severe of the acute cases of small-pox. These points are by no means unimportant, and we hope shortly to revert to them, especially in connexion with a proposal by Dr. BURDON SANDERSON, F.R.S., as to specially constructed infectious hospitals. According to the plan proposed, the hospital ventilation would be effected in such a way as to secure that all air should be forcibly drawn into the wards, and that it should be subsequently discharged into a chamber where it could be subjected to a temperature sufficient to destroy all contagion. A plan and description of such a hospital, as also Dr. THORNE THORNE'S General Report on the Use and Influence of Hospitals for Infectious Diseases, Mr. W. H. POWER'S Report on the Influence of the Fulham Small-pox Hospital, Mr. SHIRLEY MURPHY'S Report on the

Influence of the London Fever Hospital, and several other valuable documents, go to form an important Appendix to the Report of the Commission.

THE nature of Croupous Pneumonia has always been a fertile field for speculation. The opinion that it is a simple inflammation due to a simple cause long received unquestioning acceptance, until points of resemblance between pneumonia and an acute specific disease led to more careful study of its conditions of origin. It is still to these that the attention of physicians is chiefly turned. Pathologists, it is true, are seeking for its associated bacterial organisms, and we lately referred to the important observations of FRIEDLANDER on this subject; but bacterial pathology is still in too early a stage to permit much weight to be placed on the discovery of organisms in association with acute inflammation as evidence of a necessary causal relation. But the etiological facts, if well observed, have a value which no theory can shake, for they must be embraced by it as a necessary condition for its acceptance.

Many facts have lately been adduced in support of the opinion that croupous inflammation of the lung is but the local expression of a general disease, and the evidence in favour of this view has been ably summarised by an American physician, Dr. E. SANDERS, in the *New York Archives of Medicine*. The most weighty evidence is, of course, that furnished by the analogies to which we have referred, but the occasional epidemic character of outbreaks of pneumonia is an etiological point of considerable weight in support of the theory. It is necessary, however, in order to establish the specific pathology, to disprove the current opinion that croupous pneumonia may result from mere exposure to cold. Some have, indeed, been content to overcome the difficulty by the admission that there are two forms of croupous pneumonia—one due to cold, and the other a specific disease. But the sporadic cases which are usually referred to cold are precisely those which present that resemblance to acute general diseases which still constitutes perhaps the strongest part of the argument for the specific nature of the malady. Accordingly, most of the advocates of the latter view have felt that, to establish their argument, they must disestablish the current theory and disprove the dependence of croupous pneumonia on exposure to cold.

The task is one of no small difficulty, and from isolated observations perhaps impossible. Attention has therefore been turned to the comparison of pneumonia with the meteorological influences. It seems well established that the disease does not coincide in the time of its occurrence with the lowest annual cold. It is not a disease of winter, but of spring. Some facts corroborating this opinion have been lately collected in the *Revue des Sciences Médicales*. In the three great hospitals of Vienna, between 1866 and 1876, 11,442 cases of pneumonia were treated—8247 men and 3195 women. The largest number of cases were admitted in the month of April, the next largest in the month of March, and next in the month of May. KÖHNHORN observed in the barracks at Weser 300 cases of pneumonia in the course of eight years, and found that the number of cases in the three months of March, April, and May was four times as great as in the months of September, October, and November.

WARFWINGE, in Stockholm, observed a maximum in the month of May.

But we can scarcely admit the validity of the assumption that because pneumonia does not coincide in prevalence with the lowest temperature it is therefore not due to exposure to cold. The prevalence in Vienna was compared by BIACH with the meteorological report, and three conditions seemed to coincide with the disease: a sudden fall in atmospheric pressure, a low temperature, and sudden changes in temperature. A similar comparison has been made by MASSON with regard to 400 cases of pneumonia occurring at Berne and Neuchâtel; and he found that pneumonia was most frequent when the temperature of the air was low and its humidity slight; and a comparison of the conditions on the day before the onset of each case showed with great frequency a sudden fall in both temperature and atmospheric pressure. On the other hand, KÖHNHORN failed to observe any relation between his cases and the temperature; but his data appear more open to objection than the others to which we have referred.

The evidence afforded by epidemics of pneumonia would be more conclusive if such epidemics were less rare. Nevertheless they are of great interest, and certainly deserve most careful study. Some of them are described by Dr. STURGES in his work on Pneumonia, and several others have been lately recorded. HOLWEDE and MÜNNICK observed an outbreak of fifteen cases in a small village (Ober-Sikle), containing only 400 inhabitants, and in some instances as many as three persons were affected in one house. At the same time other neighbouring villages, exposed to the same meteorological influences, and in the same geological conditions, were free from the disease. In the village of Becherbach, with 460 inhabitants, BUTRY observed as many as twenty cases in the course of a few weeks, and no less than nine were fatal. The cases occurred in a small number of families, which were so grouped around those first attacked as to favour the idea of a spread by infection. In most of the cases the prostration was great; in several there were cerebral symptoms, and in five there was jaundice. In seven the apex of the lung was invaded; in five the pneumonia was double; in three there was secondary pleurisy. The spleen was not enlarged in any case. KERSCHENSTEINER observed 161 cases of croupous pneumonia in a prison at Amberg (Oberpfalz), during the four months January to May. The *materies morbi* appeared to him to be endemic and not transportable. In a district of Norway containing 6000 persons LÖBERG observed sixty-three cases of pneumonia in 1879, and twelve occurred in a limited region containing only 200 persons. The cases were grouped, several occurring in the same house. PENKERT has recorded an epidemic of forty-two cases, in which he believed himself able to trace an infection from person to person, and JELLEY observed a wife to contract pneumonia from her husband, and to communicate it in turn to a sister who nursed her. Similar cases have been noted by WYMAN. No instance, however, is more remarkable than that published in our columns by Dr. DALY a year ago, in which six members of one family were affected in the course of three weeks. The rarity and striking nature of these facts, however, may well suggest caution in reasoning from them to the familiar sporadic form of the disease.

Attempts have been made to ascertain whether the contagiousness of pneumonia can be proved by experiments on animals. KÜHN inoculated seventeen animals with the sputum of a case of "endemic pneumonia." Of the rabbits, two died on the first two days with symptoms of collapse, but in six others fever followed the inoculation, and presented critical oscillations at the end of the fifth or sixth day. Diarrhoea and prostration accompanied the pyrexia. The animals killed between the sixth and tenth day showed pleurisy and hepatisation of the lung, lobar or lobular. Five recovered. KÜHN, perhaps too hastily, regards his results as affording evidence of the specificity of croupous pneumonia.

Those physicians who find, with LECHTENSTERN, the contrast in etiological conditions between the sporadic and epidemic forms of pneumonia too striking to be ignored, and ground for a division of croupous pneumonia into two classes, have endeavoured to establish a clinical distinction between the two. SCARPARI, for example, has lately emphasised the asthenic character of the epidemic form, its association with jaundice, with yellowish fibrinous pleural exudation, the absence of resolution, and the occurrence of changes in liver and spleen similar to those which are met with in acute specific diseases. LÖBERG observed the frequency with which several initial rigors marked the onset of his cases, sometimes preceded, for three or four days, by the symptoms of catarrhal fever, and the frequency of jaundice, but he failed to find enlargement of the spleen. Several observers have noted the tardiness of resolution and the frequency with which the apex of the lung suffered. KÖHNHORN, on the other hand, at Weser, observed splenic enlargement to be the rule. It is very desirable that the actual weight of the organ should be noted in all fatal cases.

THE current number of the *Westminster Review* contains an article on River Pollution, by Mr. URQUHART A. FORBES, which possesses interest for many of our readers. Mr. FORBES has given us a vivid sketch of the still modern history of legislation in regard to the pollution of rivers, and drawn conclusions which are peculiarly apposite just now, when we all hope that further legislation is impending.

The history may be said to begin in 1848, when sewer-drainage was first enforced by Act of Parliament. The new system was extensively adopted, and it was soon found that while it did much good to the land, it did very great harm to the rivers. As London and many other towns are supplied with water from these rivers, complaints soon arose, which were intensified by the experiences of the cholera epidemics of 1854 in St. James's, and of 1866 in East London. In 1865 a Royal Commission, consisting of Messrs. RAWLINSON, HARRISON, and WAY, was appointed to inquire into the whole subject. They published three Reports, the last in 1867. In 1868 another Commission, consisting of Sir WILLIAM DENISON, Professor FRANKLAND, and Mr. J. C. MORTON, continued and extended greatly the labours of the first. The sixth and final Report of this second Commission appeared in 1874, so that the Commissions sat altogether for a period of nine years, in which time they issued no less than sixteen folio blue-books. Most valuable information respecting pollution by sewage, and by the refuse of factories, was collected. Dr. FRANKLAND in

particular, who had introduced new methods of analysis and shown the fallacy of some old ones, performed countless analyses and made experiments on purification which have the highest value, and altogether did more than any other observer in the same field, before or after. His labours resulted in the suggestion of certain standards of purity, which, it was contended, might, without undue severity, be imposed on towns and manufacturers. The whole inquiry, from first to last, cost an enormous sum of money, and is a model of patient scientific investigation.

With these ample materials in hand Mr. DISRAELI'S Government produced in 1875 a short and feeble Bill of the permissive order, in which most of the recommendations of the Commissions were completely ignored. This Bill fell through, and in the following year a second and feebler one was introduced by Mr. SCLATER BOOTH. After additional emasculation both in Commons and Lords, this second measure received the Royal assent on August 15th, 1876, and is now known as the Rivers Pollution Prevention Act, 1876. We expressed a strong opinion at the time of the inefficiency of the new measure, pointed out that it contained every element of vagueness and weakness that such an Act could contain, and predicted that it would prove a dead letter. It has long been known that this prediction has been fulfilled to the letter. Mr. FORBES tells the story so graphically, that we prefer to use his words:—

"The Rivers Pollution Prevention Act, 1876, resembles the celebrated picture told of in the 'Vicar of Wakefield,' which though it pleased Dr. Primrose and his family highly, was rendered worse than useless by the fact that it was of such a great size that it could never be got out of the kitchen where, for convenience sake, it had been painted. It is admitted to be an admirable statute, save for one fault—it cannot be put into operation. It applies to England, Scotland, and Ireland; it, for the first time in the history of legislation, recognises pollution as an offence, and punishes it by a fine of £50 a day; and it prohibits the putting of solid matter, sewage pollutions, and mining and manufacturing pollutions into rivers, streams, canals, lakes, and water-courses, other than water-courses at the passing of this Act, mainly used as sewers, and emptying directly into the sea, or tidal waters which have not been determined to be streams within the meaning of this Act by order of the Local Government Board. Yet in spite of all these merits, the few instances in which it has been attempted to enforce it since it came into force in August, 1877, have entirely failed. The reasons of this failure were made clearly manifest by Mr. Cresswell in his speech on the necessity of amending the Act at the Conference of the Society of Arts on Public Health in 1880. It is due in the first instance to the fact that it makes no satisfactory provision for the payment of costs, and hence the expenses of bringing it to bear on offenders have been so heavy as to be almost prohibitive. Secondly, like all similar enactments on the subject, it throws the onus of beginning to institute proceedings on individuals who feel themselves aggrieved by pollutions, and further requires them to act only through the local sanitary authorities, who, as has been so frequently pointed out, are the chief offenders."

Several other fatal defects are pointed out by Mr. FORBES, and we could extend the list in many ways; but enough has been said to show how perfect an example of weak and tinkering legislation the Act of 1876 was. We can only conclude with expressing an ardent hope that the result of

the Royal Commission, whose labours will recommence before these words are printed, will be not only to relieve Londoners and travellers on and by the Thames from the hideous nuisance from which they now suffer, but also to pave the way for an Act of Parliament which shall be in truth, and not merely in name, a Rivers Pollution Prevention Act.

It would be satisfactory to know that the Government intends to bring in a measure founded on the recommendations of the Royal Commissioners. We venture to hope that a question will be put to Mr. MUNDELLA which will elicit information that is anxiously awaited by the profession. We do not, of course, expect any immediate action by the Government. The present session is entirely exceptional in its character and object. It is a session practically of only one branch of the Legislature, and that for a definite purpose. The purpose in our estimate is a great one, and justifies the calling of the House of Commons together that it may exclusively be carried out. In common with other members of the Press, we have been struck of late years with the inefficiency of the House of Commons as a business instrument. When surgeons have an inefficient instrument they sharpen it. And no different device will save the reputation of the House of Commons. Apart from all political theories and partialities, there are great acts of legislation urgently demanded, which it is simply hopeless to expect so long as every group of agitators can waste week after week in noisy and unpractical declamation. We devoutly wish success to the new Rules of Procedure so far as they are calculated to make the House of Commons do more and talk less, for the disproportion between its loquacity and its acts has become a scandal and a pain to all earnest men. But though Mr. MUNDELLA may scarcely be expected to lay a Bill on the table, he would do great service by intimating at once and decisively that he meant to deal with the amendment of the Medical Acts in the direction of the report of the Commissioners. It is evident that things cannot continue as they are. There is not a medical or surgical corporation that is not perplexed with "thoughts of change." All the medical students of the period are similarly affected, and it would be the greatest boon to them to substitute the existing and fragmentary examinations by other and complete examinations. Students at present are harassed and hampered by the defects and differences of the examining boards. When they do get a diploma they find out that it is only half a diploma, and very likely that it is disparaged and aspersed by those who represent other and rival diploma-granting bodies. Our recent numbers have contained the evidence of the gross inequality of the examinations, in different parts of the kingdom, that should be practically the same. We shall soon deal with other parts of the evidence having reference to the inefficiency of the Medical Council. An educationist and a reformer like Mr. MUNDELLA cannot fail to see in this evidence, and in the report based on it, the necessity for legislation, and we venture to hope for an assurance that legislation will be undertaken in an earnest spirit.

NOTICE is given in the *London Gazette* of the 20th inst. that vessels arriving in Italy from Florida or Texas, U.S., will be regarded as infected with yellow fever and subjected to quarantine.

## Annotations.

"Ne quid nims."

### ARMY MEDICAL SERVICE IN EGYPT.

WE are glad to learn that Mr. Childers has appointed a committee to inquire into the truth of the statements which have been made respecting the alleged shortcomings of the Army Medical Service in Egypt. It will consist of the following members:—The Earl of Morley, Under Secretary of State for War, Chairman; Admiral Sir W. R. Mends, K.C.B., Director of Transports; Major-General Hawley, C.B., Deputy Adjutant-General; Major-General Sir Evelyn Wood, C.B., K.C.B., K.C.M.G.; Dr. T. Crawford, Director-General, A.M.D.; Sir W. MacCormac, M.D., and G. Lawson, Esq., Assistant Director of Supplies and Transports. The composition of the committee is a sufficient guarantee that the whole question will be carefully, honestly, and intelligently considered, and we have no doubt that valuable suggestions will be made with a view to render the service more efficient, and to remedy any defects in its organisation which may be brought to light.

### EDUCATION BASED ON THE LAWS OF HEREDITY.

ATTENTION has been recently directed—notably in a little book entitled "Youth; its Care and Culture"—to the wisdom of basing education on the laws of heredity. This is something more than a mere recognition of what are called "physiological principles." If that term, as commonly used and understood, expressed all it actually implies, there would be no need to amplify its import. Mind is brain-function, just as locomotion is one form of muscle-function. The brain, when it acts, thinks and reasons, and judges and forms purposes. As the size, weight, form, and development of the bony skeleton, with its muscular apparatus, determine the limits and nature of physical power and activity, so do the size, weight, form, and development of the brain, with its apparatus of sense-organs, determine the limits and nature of intellectual power and activity; and as the personal characteristics of the physique are in great part inherited, in like manner the personal characteristics of mind are handed down from parent to child, so that the mental and moral qualities offering themselves for culture by processes which are, in the true sense of the word, *educational* in any individual, are the sum, or the resultant, of the aggregate qualities of the two parents, *plus* the influence of congenital conditions and immediately surrounding circumstances. It is essential to recognise this initial fact, and so to order and apply the processes of education as to develop the good and repress the evil elements in the inherited character. Education ought to be individual and to comprehend a complete system of influences and processes adapted to the cultivation of the physical and mental nature in its concrete form and potentiality. There can be no greater or more ignorant blunder than to regard education as *teaching*. "Training" is a better term to use than teaching, but education in its full and practical sense means much more than both the ideas indicated by these two terms; it implies *improvement*, and "improvement, as applied to the compound organism, the physical and mental nature of man, must include the essential processes of culture, planting or grafting, uprooting or pruning, and growth-stimulation and training. Unless this threefold purpose of education—employing that term in its comprehensive and only true sense—is fulfilled, genuine improvement is impossible, whether consciousness strive to improve self, or others labour to nurture and train it. This

is true of both body and mind, subject to the mutual relations which exist between these two parts of man's nature, if, indeed, they are separate. Every child born into the world is charged with potential energies that need to be stimulated, and with some which, in the interests of individual happiness and social expediency, it is necessary to eliminate, or, at least, repress." This being so, two consequences must be seen to ensue. First, to be really effectual, each child in a school or family should be trained and taught in a manner and upon principles peculiar to himself or herself, and not by a common method or to a common pattern. Second, the surroundings of child-life, the influences brought to bear upon it, the tasks imposed, the exercises body and mind are required to perform, the food with which they are severally fed, and the *régime* to which they are subjected, ought to be carefully selected and graduated to the individual nature and its special needs. If only a tithe of the truth about education were clearly understood, it would be seen that the care of the young is not only a responsible duty, but one which calls for special knowledge, rare sagacity, and exceptional skill.

### THE MILK OF INTEMPERATE MOTHERS.

LAST week we received a letter from a correspondent, who stated that at a "blue ribbon" meeting (for women only), a working man's wife said that she was present at a similar assembly a short time before, in the course of which a physician, by way of proving to the nursing mothers present the injurious effect of intemperance on their off-spring, left the room and presently returned with a sample of milk drawn from the breast of a drunken woman, to which he then applied a light, the result being that the milk burnt for five seconds. Our correspondent, who signed herself "Incredulous," asked if this were possible, and although we had no hesitation in answering in the negative, the question raises several very interesting issues. First, as to the presence or absence of alcohol in normal human milk. It is of course well known that koumiss is an alcoholic liquor prepared from milk by vinous fermentation of the lactose; the change is a slow one, lactose being of all sugars the least susceptible of fermentation. In the milk of the cow and ass, even when freshly drawn, alcohol was found by Béchamp, the alcohol increasing if the milk was allowed to set. This of course suggests the same origin for the alcohol as in the case of koumiss. With regard to human milk, the presence of alcohol, even if found, would suggest a similar explanation, but its presence has never been proved. Still, the wife of the working man is not the first person who has made assertions as to the alcoholic milk of alcoholic mothers. On examination, however, these assertions are seen to be founded not on chemical analysis, but on statements as to the effects of the milk on the infant. In an adult these would of course consist of exhilaration, followed by swimming eyes, inarticulate speech, unsteady gait, "dyskinesia" (uterine, no doubt, in female children), and even inability to stand. We may observe many, if not all, of these symptoms in most infants at the breast; and, indeed, in this way the inability to recognise one's own father might be taken as evidence of double vision. Is, then, the whole infant population to be regarded as more or less permanently drunk? Again, evidence may be obtained from the remoter effects of alcohol. We have heard a story of a child who died of cirrhosis of the liver from the prolonged exhibition of steel wine; but we may safely affirm that if even a trace of the alcohol constantly imbibed by a large proportion of nursing mothers were to find its way into their milk, specimens of infantile cirrhosis would be far from rare. On the other hand, there is no doubt that some of the alcohol of alcoholic mothers not unfrequently finds its way into the

system of their infants by a more direct route than the milk. Setting aside, therefore, the question of alcoholic human milk as contrary to fact, one question still remains—namely, that of the general effects of alcoholic drinks on the milk of nursing women. To this question no short answer can be given. It may be stated at once, that the diet which ensures the best state of health and nutrition also ensures the best milk, but that no hard-and-fast rule can be laid down on the subject. Overfeeding, as well as underfeeding, will often impair both the quality and quantity of the milk. It is, however, as in so many other questions, highly unscientific to lump all alcoholic drinks together, seeing that in those most generally useful, the alcohol is by no means the principal ingredient. To put gin and mild beer and claret together is to collect strange companions, who have, indeed, a common property, but little more. We are, however, within the mark in saying that, special medicinal questions apart, no nursing woman should drink spirits; that the less stimulant she can take (consistently with good health) the better; but it is no less true that in mild malt liquors, and especially in sound porter and stout apparently from the special preparation of the malt, we have a very simple and excellent stimulant to the lacteal secretion in many cases where it flags, and even in some cases where malt alone or other stimulants have failed. Of the impoverishment of the milk of women whose health is impaired by drinking there can be no reasonable doubt, and too much can hardly be stated in this respect. We quite agree with the blue ribbon orator so far as this, that if all nursing mothers were teetotallers it would be far better for the totality of British babies. In saying this, however, we must add that some infants would, in our opinion, be the worse; but that, on the principle of "the greatest good for the greatest number," more would be benefited than injured. If only those nursing mothers took stimulants whose health was really improved by them, it would be better still. There are facts which seem to show that alcoholism produces in some women a functional or temporary sterility. On this question, being beside our present subject, and also as not unlikely to serve as an incentive, or at least an excuse, for intemperance, we will not enter. Is it not somewhat of an irony of fate that the teetotal cow and ass should produce alcoholic milk, while the alcoholic human female produces none?

#### HÆMORRHAGE AFTER EXCISION OF THE TONSIL.

THE removal of an hypertrophied tonsil is a frequent and simple surgical operation, in connexion with which any complication is so infrequent as to be unheeded by many operators. Experience abundantly proves, however, that it is not unattended with danger from hæmorrhage, one of the most serious features of which is that it may not be primary but intermediary, or what is usually spoken of incorrectly as "secondary." There may be only the usual slight amount of hæmorrhage at the time, and then some hours later a profuse flow of blood occurs. This fact it is which gives additional import to the complication. Dr. Lefferts, of New York, has recently drawn attention to this subject, and has recorded cases in which the bleeding has been profuse, and discussed the appropriate treatment. In this country, we believe it is a not infrequent plan to give every patient an astringent powder to be moistened with water and introduced into the back of the throat should bleeding come on. Dr. Weir has recently recorded a case of this intermediary hæmorrhage, which illustrates well one cause of it, and the explanation of its mode of occurrence. One tonsil of a young man was removed with a guillotine; there was slight hæmorrhage at the time, but several hours afterwards, severe loss of blood—estimated at a pint—ensued, which was controlled by the

application of persulphate of iron and by pressure; the bleeding recurred twice subsequently. When Dr. Weir saw the patient he found that the bleeding vessel was an artery in the anterior pillar of the fauces. The vessels of the tonsils are small and lie in soft tissue, which readily permits of their natural closure when severed, and the various movements of the throat do not of themselves disturb the wounded vessels. Not so is it with the palatine arteries; they are, in the first place, larger, and, as they lie in the muscular tissue of the palate, when wounded they are constantly exposed to disturbance from the contractions of the palate muscles in deglutition. If one of these vessels be wounded then, in the operation of excising the tonsil, not only is the hæmorrhage freer than from the tonsillar vessels, but there is a great tendency to recurrent bleeding from the constant movements to which the wounded vessel is exposed.

#### THE MUNICH ELECTRICAL EXHIBITION.

IN addition to a varied display of electricity as applied to technical uses, there is a special branch of the above exhibition devoted to the illustration of the employment of this force in theoretical and practical medicine. In the descriptive remarks which Dr. Stintzing has published on the subject, he alludes to the value of electricity as an exciting medium when judiciously applied to various parts of the human organism, and remarks that electro-physiology has done much to increase our knowledge of the properties and functions of the nervous system, the muscles, the glands, &c. Another important branch of medical science connected with electricity is the diagnosis of certain diseases by means of electrical tests applied to the living body; on which subject he further remarks that physiology teaches us the laws as to convulsive motions, according to which the nerves and muscles are affected by the exciting power of electricity. For instance, if an electrical current (whether constant or interrupted) of a given strength be applied to a nerve, the muscles with which it acts are excited and become contracted according to fixed laws. In these involuntary reactions of the organs of motion upon the electrical current it makes a difference whether the latter passes through the nerves in an ascending or in a descending direction, and whether the action of the positive or negative pole preponderates. When the body is diseased, these physiological laws are subject to changes, and by carefully noting the deviations from the general rules which may be observed in the application of the electrical current in different ways to sick persons, conclusions may be drawn of practical value in the diagnosis and prognosis of such cases and in the regulation of the most suitable form of treatment for them. Electro-diagnosis and electro-therapeutics go hand-in-hand, and the exhibits at Munich affecting medical electricity illustrate both subjects; the appliances connected with the former being of course the more complicated. The Munich Medical and Clinical Institute and various manufacturing firms exhibit instruments of great exactness for ascertaining and regulating the force of the electrical current. A great variety of instruments and appliances of a portable form, suitable for general use by medical men, are also exhibited, including batteries, communicators, wires, &c., constructed with special reference to the different models which the various parts of the body require for the successful application of the electrical currents. For electro-therapeutical purposes the accurate measurement of the strength of the electrical current is indispensable, and the simple yet effective galvanometers for this purpose, made in two sizes by Dr. Edelmann of Munich, at the suggestion of Professor von Ziemssen, are highly spoken of. In contrast with the use of electricity, as applied by means of batteries and inductive appliances, the employment of electricity obtained by friction has been specially recommended of late by

Dr. Stein of Frankfurt, and various instruments &c. required for the application of this method are exhibited by Messrs. Albert, of that city. The photographs illustrative of the effects of electricity upon the nerves and muscles, and other representations showing the muscles, or groups of muscles, most easily affected by the electrical current, are interesting adjuncts from a medical point of view. Dr. Stintzing also refers to an electro-endoscopic apparatus, which is applicable to diagnostic purposes. It is intended for the partial illumination, by electrical means, of the ear, nose, jaws, and other portions of the human body. In the same category mention is made of two small endoscopic instruments exhibited by Dr. Michael, of Hamburg, in which phosphorescent substances are subjected to the influence of an electrical discharge.

#### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

THE present Council of this old-established Society, under the guidance of its President, Mr. Marshall, and the Hon. Secretaries, Dr. R. Thompson and Mr. B. Hill, have been carrying out certain "innovations," which, although, as the President stated, of comparatively minor importance, are steps in the right direction to ensure a high standard of merit in the papers read before the Society, as well as to enhance the value of the debates arising upon them. One of these innovations is the printing of the abstracts of the papers three or four days before the meeting, so as to enable intending speakers to obtain copies of these abstracts for private perusal and study. In this way it is hoped that the speeches will be more matured and more distinct contributions to knowledge, adding greatly to the importance of the discussions. Authors of papers are also to be allowed, when deemed necessary, to read their own papers. Hitherto this task has devolved upon the Hon. Secretaries, and we think the change one which will greatly facilitate the proceedings of the Society. Reports of the discussions are also to be printed in the Society's Proceedings—a step which will, it is thought, and rightly, cause this publication to be more read than it is at present. Another feature of the meetings is the addition of demonstrations of subjects of scientific interest, new inventions of practical and scientific value, new subjects in anatomy and pathology, &c., all with a view to render the meetings more attractive and useful. In each and all of these directions we think the Council has acted most wisely, and we trust that the communications made to the Society will maintain the high reputation it has already gained, and increase the attendance at the meetings. It may be added that during the recess considerable structural alterations have been made in the Society's rooms, and a great improvement has been effected in the lighting of the main hall.

#### A NEW VEGETABLE STYPTIC.

A RECENT number of the *Neus Freie Presse* states that during the French expedition to Mexico a plant was discovered, called by the natives by a name which may be rendered as "Fowlwort" (*Tradescantia erecta*, Jacq.), which has the property, when chewed or crushed, of stopping any hæmorrhage. A specimen planted in 1867 by the discoverer, in his garden at Versailles, has not only flourished, but flowered and fruited, without having its peculiar properties as yet appreciably diminished. Although no exotic, or remarkable for particular beauty of bloom, it, nevertheless, deserves a wider extension on account of its valuable properties, especially as its acclimatisation may be regarded as having been fully established. Its action exceeds that of all styptics as yet known, as, for example, perchloride of iron, and it can, moreover, be very cheaply procured.

#### THE DANGERS ATTENDING SHAMPOOING.

RECENT and unsatisfactory experience in one or two West-End hair-cutting saloons leads us to inquire whether sufficient care has been bestowed on the sanitary management of the shampooing contrivances. Those persons who avail themselves of the very refreshing pleasures of a "shampoo" must, however, have noticed that they are compelled to bend over, and bring their faces in close proximity with, the hole in the centre of the huge basin used for this purpose. If they watch the soapsuds that form round this hole before any large volume of water is allowed to flow, they may perceive the air coming up the pipe; for it inflates the soap and forms a large bubble that bursts close under them. Whatever may be within, it is too near to avoid breathing its contents. Nor does the absence of any suspicious odour inspire a sense of security; for it is very evident that even a strong whiff of sewer gas would be lost in the scent that perfumes the soap and surrounding atmosphere. If therefore the pipes attached to the basins communicate direct with the house-drains and the sewer, there is surely some danger that the atmosphere breathed within a couple of inches of the aperture may carry, disguised under the fragrant of the rose or jasmin, the virus of disease. In one of the most celebrated West-End houses we noted that the pipes from the shampooing basins all led on to the roof of an out-house, and there the soapsuds and water travelled some three or four yards in the open air before reaching the water-spout that conveyed them to the sewer. A back current could therefore only bring in air from the roof—that is, air as pure as any to be had in London. But in another house nearly as celebrated the pipe from under the basins ran direct to the drains. There was no S-trap visible, and apparently no intercepting ventilation. The basins had, in fact, all the appearance of so many sewer mouths, ventilating the sewer-gas into the faces of the customers as they leaned over the aperture. Even a syphon in such cases is not, we maintain, a sufficient protection; the constant flow of water, the difference of temperature between the hot and cold water, and the varying degrees of density of the water through the presence in small or larger quantities of soap, oil, &c.,—all these circumstances must so affect the pressure and tension of the air within the pipes as to produce suction, up currents, and syphonage. Consequently it is indispensable that all the pipes conveying the waste from hairdressers' saloons should empty in the open air over a gully-trap or an interceptor, and should not have any direct connexion with either the house drains or the public sewer.

#### SUMMER DIARRHŒA IN 1882.

JUDGED by the figures published from time to time in the Registrar-General's weekly return for twenty-eight of the largest English towns, with an aggregate population of about eight million and a half of persons, it is evident that the fatality of diarrhœa during the past summer, although slightly higher than it was last year, was again considerably below the average. In London the annual death-rate from this disease showed a larger proportional decline than in the provincial towns, and did not exceed 1.5 per 1000, against 3.2 and 2.5 in the summers of 1880 and 1881. The rates in the large provincial towns showed the same, a similar variation which should throw light upon the true causation of this disease, but which has not yet led to its satisfactory explanation. During the thirteen weeks ending September 30th last the death-rate attributed to diarrhœa did not exceed 0.9 in Halifax, 1.0 in Bristol and Derby, and 1.3 in Plymouth and Huddersfield, whereas the highest rates in the other provincial towns were 4.0 in Leeds, 5.7 in Leicester, 5.8 in Hull, and 6.0 in Preston. All these towns are old offenders in respect of infantile diarrhœa, and

of infant mortality generally. It is also noticeable that while, as we have stated, the death-rate from diarrhoea last quarter in these large towns showed a general increase upon that in the corresponding period of 1881, the rate of increase varied in a marked manner; indeed, in several of the towns the rate showed a decline. All these facts point conclusively to controlling influences other than meteorological. It may be hoped that the Local Government inquiry on this subject, now being conducted by Dr. Ballard, will throw satisfactory light upon this much discussed but yet unsolved problem.

#### THE LATE PROFESSOR BALFOUR.

AN influential meeting was held on Saturday last in the Lecture room of Comparative Anatomy at the New Museum, Cambridge, to consider the best mode of establishing in the University a memorial of the late Professor Balfour. The Vice-chancellor presided, and the meeting was attended by Professor Huxley, Messrs. H. Smith, Lankester, Foster, Paget, Humphry, Newton, and others. Great regret at Professor Balfour's untimely close of a career so full of promise was expressed by every speaker. Professor Paget proposed the first resolution, that a memorial of Professor Balfour be established in the University of Cambridge, which was seconded by Mr. H. Smith. In supporting this resolution Mr. Adam Sedgwick instanced as proof of the attractive address and teaching of Professor Balfour that his class which at first only consisted of ten or twelve students, had in the course of seven years increased to ninety. Professor Huxley then proposed that the memorial take the form of a fund to be called the Balfour Fund for the promotion of research in biology and especially animal morphology. Professor Newton proposed, and it was unanimously agreed upon, that the proceeds of the fund should be applied to establish a studentship, the holder of which shall devote himself to original research in biology, especially animal morphology, and further, that the fund should supply occasional grants of money for the furtherance of original research in the same subjects. Professor Foster finally proposed that the studentship should be endowed with £200 per annum, and that it should not be given away by competitive examination. It was stated at the meeting that £3000 had been subscribed by the family of Mr. Balfour, and that £1000 which he had himself bequeathed to Professor Foster would be expended in promoting the objects aimed at in the memorial.

#### TUBERCLE OF THE CHOROID.

AN interesting discussion took place at the Ophthalmological Society on the 12th inst. upon the significance of choroidal tubercle. Examples of the disease were related by Drs. Mackenzie, Warner, and Brailey, and the discussion turned chiefly upon a point raised in the communication of the second-named gentleman—namely, whether the choroidal affection were not more frequently met with as a part of general tuberculosis than in association with tubercular meningitis simply. The question produced some slight divergence of opinion,—such experienced observers as Dr. Baxter, Mr. Hulke, and Mr. B. Carter stating that tubercle of the choroid was of extreme rarity in cases of meningitis, and therefore the inference is that much reliance cannot be placed upon it in determining a diagnosis, or rather that its absence proves nothing in the exclusion of a diagnosis of tubercular meningitis. On the other hand, Dr. Barlow mentioned that he had detected it in as many as twenty cases, verified on post-mortem examination. After all, the issue seems to have been a narrow one; for it must be borne in mind that in the vast majority of cases of tubercular meningitis there is tuberculosis of other viscera, and that the meningeal affection is as much a part of the

general dissemination of tubercle as is the choroidal. At the same time this fact is plain, that tuberculosis of the choroid no more depends upon tuberculosis of the pia mater than this latter does upon tuberculosis of any other organ. Dr. Sansom's contribution to the discussion was instructive. He cited a case with symptoms of meningitis in which he had given a most unfavourable prognosis because ophthalmoscopic examination revealed choroidal tubercle. The event proved one of three things: either that tubercular meningitis is not necessarily lethal, or that tubercle may exist in the choroid without being present elsewhere to any grave extent, or that the ophthalmoscopic diagnosis of choroidal tubercle is open to fallacy. Which of these interpretations is the most likely must remain undecided, but it is to be regretted that Dr. Sansom had no opportunity of again examining the eye after the recovery of the patient from the meningitis. The attention thus drawn to the subject should encourage investigation into the occurrence of choroidal tubercle, not only as detected by the ophthalmoscope, but as found in post-mortem examination of all cases of tuberculosis.

#### SIR THOMAS WATSON, BART.

THE whole profession will learn with deep concern that the health of this revered physician has during the last few days been a source of anxiety to his family and friends. He had for some weeks past been staying with his son at Reigate. On Sunday last, although now in his ninety-first year, he was in his usual good health and attended the morning service. On attempting to rise from his chair after lunch he suddenly inclined towards the left side, and would have fallen on the floor if he had not been supported by his son. He afterwards took a short walk in the garden, but there was an evident weakness of the left leg, and this continued to such a degree that he is now unable to walk without assistance. There is no appreciable loss of power in the arm, but the tongue when protruded deviates slightly to the left. There has been no drowsiness, and he is in complete possession of his mental faculties. His kind neighbour, Dr. Walters of Reigate, is in daily attendance, and he has been visited by his old pupil and friend Dr. George Johnson, to whom he calmly remarked, "This is the beginning of the end." His medical attendants are agreed that there is probably some arterial obstruction by thrombosis in the neighbourhood of the right corpus striatum.

#### IRISH LUNATIC ASYLUM REPORTS.

THE twenty-first report on Irish Lunatic Asylums, for the year 1881, states that at the end of the year there were in the twenty-two district asylums 8667 patients, 4685 males and 3982 females, being an increase of 311 during the year. Of 2044 admissions, 453 were relapses, and from this the deduction is made: "That while medical science is able to contend with physical affections to a great extent, the mind is beyond its control, as a rule, save when bodily diseases may have superinduced in it an unhealthy action." This would convey the impression that the mind was regarded as an entity at times entirely independent of physical causes. Would it not be possible to suggest several other equally probable explanations of these figures. The recoveries are estimated at 40 per cent. on admissions, or 11½ per cent. on the daily average of patients. The death-rate is low, 7½ per cent. on the number under treatment. The inspectors defend themselves from a charge of a disposition to extravagance very tersely and truly. They say: "A waste of money arises when an expenditure is too restricted to be useful. In fact, our only desire is to locate in public asylums suitable inmates, ensuring at the same time in each district a becoming receptacle for others who need less attention." Great liberality

in salaries and pensions of the asylum staffs is advocated, and would seem to be very necessary from an examination of the tables in which the former are stated. There are 3600 persons mentally afflicted in poor-houses, and the inspectors advocate that a poor-house in each asylum district should be solely devoted to the care of harmless lunatics, thereby avoiding the construction of additional asylum accommodation, many of the asylums already containing a considerable excess of patients over their estimated capacity. There can be little doubt that this plan is well adapted to the wants of the country, and is an example of the practical appreciation of their work which the inspectors manifest throughout their report.

#### THE NEW BUILDINGS OF THE MEDICAL SOCIETY OF LONDON.

SOME months ago the property between the Medical Society's Rooms in Chandos-street and the corner house in Cavendish-square was to let. The Society has been fortunate enough to secure it together with its old holding on a long lease at very reasonable terms. This has afforded an opportunity of constructing additional accommodation, as well as of remodelling the existing premises of the Society. The part of the building to be erected on the newly-acquired land has already advanced considerably, and is nearly ready to be roofed in. The new building, as designed by Mr. H. C. Boyes, of 9, Bow Churchyard, will extend along a frontage of about 120 feet in Chandos-street. It will comprise two stories, covered by a Mansard roof containing a third. The plan of the ground-floor, besides an entrance and staircase-hall, with ample cloak-room and lavatory accommodation, provides several suites of offices, which will be sub-let, as now, for business purposes. From the hall a semicircular staircase ascends to a wide landing, from which the rooms of the Society open. To the left is the council-room, and a corridor leading to a small library to be occupied by the Entomological Society. Facing the stairs a door gives access to the present meeting-room, which, enlarged by an annexe, is retained as the future library. To the right opens the large new meeting-room, 38 ft. by 26 ft., and 19 ft. high, occupying all the north wing of the old building. From the corridor a staircase leads to the Registrar's apartments above. It has fortunately been found possible to regulate the builder's operations so as not to interfere with the working of the Society during its session. The meetings will take place as usual in the existing meeting-room until the new one is ready to receive the Fellows. Though access to the library is at present debarred, this inconvenience will, it is hoped, be shortly removed. On the completion of these alterations it is believed that this ancient Society will be housed in a more commodious manner than any of its younger rivals; while its very valuable, and far too little known library, so rich in old medical works, will be more advantageously placed than hitherto.

#### THE ORGANISMS OF TYPHOID.

MARAGLIANO of Genoa has published, in the *Centralblatt für die Med. Wissenschaften*, an important note on the uniform occurrence of organisms in the blood of patients suffering from typhoid. He has found them in the blood of the spleen as well as in that of the general circulation. The blood was obtained by means of a hypodermic syringe, the middle of which was passed through the abdominal wall into the substance of the spleen. Dr. Sciamano of Rome first showed that blood may be thus obtained from the substance of the spleen during life without any injurious consequences. The blood of the general circulation was taken from the tip of the finger. In each method every precaution was taken

to avoid the accidental introduction of organisms. The examination, in this way, of fifteen patients gave the following result. At the height of the disease the blood of the general circulation contains micro-organisms both isolated and grouped. These consist, almost exclusively, of spherical bodies, which have a delicate contour, appear to be homogeneous, and are analogous to micrococci. Some of them are mobile. Similar organisms, again, were seen in the blood of the spleen, and in it, too, were others, rod-shaped, also with delicate outlines, perfectly corresponding to those described by Eberth and Klebs. During convalescence these micro-organisms lessen in number in both the splenic and systemic blood. When quinine was given to the patient in large doses the organisms either disappeared from the blood, or were present in it only in small number. The blood from both the finger and the spleen was treated by the method of fractional culture, and a large number of rods were then obtained, similar to those seen in the fresh blood except that some of them were of greater length. The presence of such organisms in the blood of the spleen after death had been previously established by Sokoloff and Fischel, but Maragliano is the first who has demonstrated their presence in the splenic blood during life. He avoids the expression of any opinion as to their relation to the disease.

#### REMOVAL FROM THE MEDICAL REGISTER.

THE customary caution as to the risk of being erased from the Medical Register is published by the Registrar in our advertising columns. It cannot be too clearly apprehended by our readers that any change of address should be intimated to the Registrar of the division of the kingdom in which their registration first took place; and that in the event of letters of inquiry being sent to registered practitioners and remaining unanswered, the Registrar's instructions are to erase their names. Much irritation has been caused by such erasures, but they are strictly in accordance with the Act of 1858. They may all be avoided in the Register of 1883, which is now being prepared, by the timely answering of letters addressed by the Registrar to registered persons, and by timely intimations of change of residence. It is exceedingly unsatisfactory to find one's name omitted, without one's crime, from the great roll of the profession. We are convinced that it is the desire of the Registrar to make his Register as correct as possible, and that the profession will co-operate with him in making it so, even if they think that the method prescribed in the Act admits of amendment, like so many other parts of the Act of 1858.

#### ILLEGITIMACY AND MANSLAUGHTER.

DR. A. L. WEATHERLY, deputy coroner for Somerset, is reported by the *Bristol Post* to have made some very appropriate observations in the case of an inquest on the body of a newly-born female child, the illegitimate offspring of a young woman in the service of a family at Poolridge. As the servant was found guilty by the jury of manslaughter, we think it well to postpone comment, excepting on one point. Both the mistress of the girl and an elderly woman who frequently worked at the farm suspected that the girl was in the family way. It is wrong when experienced women notice young women to be in the family way, and even suspect them to be in labour, not to say anything about it. It is no doubt painful to recognise that a young woman is illegitimately pregnant; but it is monstrous to refuse to recognise it. As the coroner pointed out in this case, the consequence of doing so is that a young woman finds herself committed on a charge of manslaughter. Had her friends or her mistress, or her fellow servant, determined to ascertain the truth of their suspicions, the girl would have been saved from an extremely painful position.

### VISITATION OF THE MEDICAL CORPORATIONS BY THE MEDICAL COUNCIL.

OUR readers are aware that the examinations of the nine medical and surgical corporations of the United Kingdom were recently visited and reported on by three visitors of acknowledged competence and impartiality, Professor Gairdner, Mr. Stokes, and Mr. Teale. Though the immediate result of their reports and the conclusions of the Council were somewhat disproportionate to the expectations raised and the money expended on the visitation, yet the reports contain a great amount of information and criticism. These reports and the answers of the bodies to the criticism of the visitors make up a volume of considerable interest and value at the present moment. It is made much more so by an index, the preparation of which must have entailed great labour and trouble. This, together with all the publications of the Council, can be had of Messrs. Spottiswoode.

### BANQUET TO THE MEDICAL OFFICERS OF THE EGYPTIAN EXPEDITION.

WE understand that it is intended at an early date to give a banquet of welcome to the medical officers of the army and navy who served in the Egyptian expedition. The chair will be taken by Sir William Jenner, Bart., K.C.B., President of the Royal College of Physicians. Sir James Paget, Bart., Sir Joseph Fayrer, K.C.S.I., Medical Officer to the India Board, and Mr. T. Spencer Wells, President of the Royal College of Surgeons, have expressed their intention of attending the banquet, and Dr. Crawford, Director-General of the Army Medical Department, and Dr. Reid, Director-General of the Naval Medical Department, will also be present as guests. A committee is being formed to make the necessary arrangements; meantime, communications from gentlemen desiring to attend may be addressed to Mr. G. Eastes, M.B., 69, Connaught-street, Hyde-park, W.

### BLOOD AND OZONE.

It is usually asserted by physiologists that even traces of ozone, introduced into the blood, injure it by leading to the formation of methæmoglobin, and conversely ozone in contact with blood quickly undergoes destruction. The question has been reinvestigated by Professor Binz of Bonn, who has found that pure ozonised air has an action on human beings quite similar to that of nitrous oxide. Persons whose respiratory passages are so little irritable that they can take a full inhalation, experience a brief agreeable stimulation, and then become somnolent and actually fall asleep for a short time. This observation has led him to make further experiments on the tolerance of blood for ozone. He found that a stream of ozonised air might be passed through defibrinated blood for at least an hour without the occurrence of any change in its aspect, or microscopical or spectroscopical appearances. The only difference is that the alkalescence diminishes more than in similar blood, through which simple pure air is passed. The ozone manifestly first combines with the dissolved organic elements of the blood, and only acts on the formed elements after prolonged action. A small quantity of blood subjected to a similar current of ozone first becomes bright red, then darker, and, at the end of an hour, it resembles reduced blood in aspect, but differs from this in not regaining its tint when shaken up with air. Its spectrum presents weak but unmistakable oxidation lines, which are not accompanied by methæmoglobin lines until the following day. Microscopically the blood-corpuscles were pale, and apparently spherical, and no fragments were visible. In another series of experiments the ozonised air was passed through fresh blood, to which a little saline solution had been added.

At the end of ninety minutes the blood was uncoagulated, dark, but still showing oxygen lines, and the corpuscles had lost their depressions. A longer exposure rendered the blood very dark, and the next day the corpuscles had disappeared, and the methæmoglobin had considerably increased in quantity. A solution of pure oxyhæmoglobin resisted the action of the ozone much less than the blood, although it never presented alterations in less than ten minutes. Binz further ascertained that the decomposition of ozone by blood is not complete; considerable traces seem to remain in the blood in an unaltered state, and can be recognised by the usual tests.

### OUR ORIGIN AS A SPECIES.

THE first number of *Longman's Magazine*, to whose prosperity we wish well, contains an article by Professor Owen with the above title, and which is a polemic upon a paper by Grant Allen in a late number of the *Fortnightly*. That author had rather strongly insisted on the evolution of man from some man-like animal developed from the anthropoid apes, and living about the mid-miocene period; a creature that was partly frugivorous, partly carnivorous—a tall and hairy creature, more or less erect, but with slouching gait, black-faced and whiskered, with prominent prognathous muzzle and large pointed canine teeth, those of each jaw fitting into an interspace in the opposite row; the forehead low and retreating, with bony bosses underlying the shaggy eyebrows; his brain about halfway between that of the anthropoid apes and that of the Neanderthal skull. Then came the Pleistocene period, and with it the age of the cave-men, who presented some similarity to the existing Eskimo, but with lower foreheads, with high bosses like the Neanderthal skull, and big canine teeth, like the Naulette jaw. Professor Owen, in commenting upon these statements, observes that the human jaws of this supposed period which he has examined give no evidence of a canine tooth of a size indicative of one in the upper jaw necessitating such vacancy in the lower series of teeth, as the apes present. He refers to the skulls he himself obtained from the cavern at Bruniquet, and now in the Museum of Natural History, which show neither lower foreheads nor higher bosses than do the existing races of mankind, and he makes an observation which, coming from such an expert, is of great weight—that, so far as his experience has reached, there is no skull displaying the characters of a quadrumanous species, as that series descends from the gorilla and chimpanzee to the baboon, which exhibits differences, osteal or dental, on which specific and generic distinctions are founded, so great, so marked as are to be seen in the comparison of the highest ape with the lowest man. Clearly the missing link has not as yet been discovered, and many more undoubted specimens of river-drift and cave-men must be collated before any positive statements can be made.

### PEAT DRESSINGS.

AT the suggestion of Dr. Neuberg, Professor Esmarch has recently been using in his hospital at Kiel bags of peat-dust impregnated with an antiseptic. This dust is very light and powerfully absorbent of gases and liquids, taking up more fluid, it is asserted, than jute, gauze, or cotton wool—even to nine times its own weight; it is also soft and elastic, and in Germany very easily obtained and inexpensive. The peat may be used alone in bags of muslin, but the more approved method is to have two bags of muslin—one twice the size of the other—purified by being wrung out in carbolic solution, 5 per cent. The smaller is filled with the peat-dust containing  $2\frac{1}{2}$  per cent. of iodoform, and is placed immediately in contact with the wound. The larger bag is filled with the peat-dust soaked in carbolic solution, 5 per cent., and this is placed over the other. Such

a dressing may remain undisturbed for from several days up to a fortnight, and it is stated that excellent results have been obtained with it. This we do not doubt, but we are unable to believe that this newest form of "antiseptic" dressing will in any way revolutionise surgical practice or become generally adopted.

#### NOTIFICATION OF DISEASE TO THE VICAR

THE heading of our annotation may suggest an additional argument in favour of notification to the sanitary authority. The opponents of such a measure, in whatever form, may see that the notification of infectious disease is so taking hold of the public mind that, if the medical officers of health and the sanitary authorities do not make themselves recipients of the information, other authorities will inter-meddle. In *St. James's Parish Magazine*, Tunbridge Wells, the following suggestion is made: "Notice of any infectious case, such as scarlatina, measles, &c., should be at once communicated to the vicar, that it may be promptly taken in hand, and the infection be as far as possible prevented from spreading." We should have thought that the vicar had quite enough on hand, in all the sin and vice of his parish, without the addition of cases of measles and scarlatina. But it is clear that the sanitary authority of Tunbridge Wells has a serious rival in the ecclesiastical sphere.

#### EXCISION OF THE PYLORUS.

ON the 17th inst., at St. Thomas's Hospital, Mr. Sydney Jones removed the pylorus for malignant disease. The patient, aged fifty-seven, was under the care of Dr. Bristowe. A large growth completely surrounding the pylorus, together with some affected glands, was removed. The operation was a prolonged one, and was carried out with antiseptic precautions. The patient was much emaciated before the operation, and unfortunately did not rally from the shock, dying about six hours afterwards. We hope shortly to publish the particulars of the operation and morbid appearances.

WE regret to have to record the death of Wm. Alexander Anderson, M.D. Aber., F.R.C.S. Eng., of Uxbridge. The deceased had been in the Commission of the Peace for Middlesex for some sixteen years, and was one of the most active members of the Uxbridge bench of magistrates up to the time of his death, which took place suddenly on Sunday last. Dr. Anderson was formerly assistant-surgeon at the Royal Naval Hospital, Plymouth, and took his Fellowship of the English College of Surgeons in 1853.

THE Regius Professor of Medicine at the University of Oxford has issued a notice requesting candidates for a certificate of proficiency in subjects bearing on Preventive Medicine and Public Health to send their names to him on or before Friday, Nov. 10th. No person can be admitted as a candidate who has not obtained the degree of Bachelor of Medicine in the University.

THE terrible hurricane which has played such havoc with the buildings of Manila would seem to have verified the truth of the adage that "it is an ill wind that blows no one any good." It is stated that on the first day after the storm not a single case of cholera occurred in the town or the island.

IN January next (says the *New York Medical Record*) a night medical service will be established in Brooklyn. In Washington, D.C., where the plan has been in operation some little time, the calls average between one and two every night.

By the death of James W. Johnston, M.D., Honorary Surgeon to the Queen and Inspector-General of Hospitals and Fleets (retired), a good-service pension of £100 a year is placed at the disposal of the First Lord of the Admiralty.

DR. F. W. KÖHLER, of Louisville, performed resection of the stomach for cancer on September 2nd last. This operation is stated to be the first of its kind done in America.

#### TREATMENT OF THE SICK AND WOUNDED IN EGYPT.

[FOR the following account we are indebted to Mr. Edgar Crookshank, house-surgeon of King's College Hospital, who, having arrived at Ismailia in the *Lydian Monarch*, was attached to the medical staff in Egypt, and followed the campaign from the base of operations to Cairo. His notes are not only valuable from his previous acquaintance with the methods of antiseptic surgery as carried out in its minutest detail at King's College Hospital, but more particularly as they tend to show that the alleged deficiencies in the care of the wounded and the administration of medical comforts were based on a want of sufficient professional acquaintance with the working of the Medical Department.—ED. L.]

Various accounts having been circulated with regard to unsatisfactory treatment of the sick and wounded in Egypt, a few notes of my experience during the campaign may be of interest to the profession.

Arriving at Ismailia in the *Lydian Monarch*, I was attached to the base hospital on Aug. 29th. Having the free run of the hospital, and being desirous of gaining experience in every particular, I keenly observed its working. At the time I arrived, I was greatly pleased with the cleanliness, ventilation, and general sanitation of the building. In the surgical division in which I worked, I was at once struck with the wholesome condition of the wards and the absence of that peculiar unhealthy atmospheric condition which so speedily results in overcrowded or ill-ventilated hospitals. The isolation in tents of the infectious cases, the suspension of carbolic sheeting, and the use of tea-leaves sprinkled with carbolic acid in sweeping out the wards, were the chief means in use for the preservation of the purity of the air. Equally satisfactory was the general appearance of the wards, the patients lying on mattresses arranged with sufficient interval to secure for each the requisite amount of ward space, and surrounded, when the cases were severe, with mosquito curtains. Folded coats and helmets were neatly arranged in the corners or where they were out of the way; and in the centre, chatties, and occasionally even flowers, were placed on empty packing-cases covered with clean towels.

Whilst dressing patients and conversing with them, with the exception of the incidents to which I will subsequently refer, I always found that they expressed themselves as comfortable, as having all they wanted, and grateful for the care and interest taken in them by the surgeons. The room set apart for operations, containing an operating table in the centre, and an extemporised table on one side, arranged with all the instruments, dressings, bowls, sponges, and solutions necessary, could not possibly have been more suited for its purpose if it had been the operating theatre of a civil hospital. Whenever a serious case was under notice a consultation of two or more surgeons was held, and the case thoroughly entered into and discussed. Conservative surgery was the golden rule persistently adhered to, and

therefore it will be seen how groundless could be any complaint of inattention or unnecessary mutilation. One case has been especially referred to—viz., that of a Life Guardsman, whose arm was amputated at the shoulder-joint. This required the services of two surgeons to attend to the dressing daily, and as, arriving shortly after the operation, I was requested to be one of the two, I inquired minutely into all the details of the injury and of the operation, and I am perfectly sure that chloroform was administered. With regard to his after-treatment, I can speak with certainty; he was not only always dressed with the utmost care and gentleness, but any little fancy that he had was promptly attended to. For instance, he used to ask for champagne, beer, chicken, fish, beefsteak or chops, and a special requisition was then made, and if it were possible—which was nearly always the case—his wish was gratified. The report of the deficiency of anæsthetics was utterly inaccurate. I was myself detailed for the inspection and distribution of antiseptic dressings and appliances which had been supplied in large quantities, and it was necessary for me to go through the invoices of all the medical stores deposited in the cellars of the hospital. I remarked, while doing so, how amazed I was at the quantity of every drug, dressing, and appliance that could possibly be required, and my attention was specially drawn to the rows and rows of bottles of ether (in addition to the chloroform)—a most gratifying sight for those who of late have commented so much on the superiority of this anæsthetic. At the majority of the operations at the base hospital I was present, and not only in operations, but also in all difficult cases where it was necessary to inflict pain in making a careful examination, an anæsthetic was administered. The heart having been examined, chloroform was nearly always used, being given by means of Skinner's inhaler or by the Listerian method, on a towel. Such was my experience at the base.

On September 11th I was ordered to proceed to Kassassin, and, being attached to the advanced-field hospital, I accompanied the force and was present at the battle of Tel-el-Kebir. From the battlefield the wounded were brought by the stretcher- and dhoolie-bearers to tents which were pitched by the side of the canal. Cases and panniers were quickly opened, and everything was ready when the wounded came pouring in. The surgeons and men of the Army Hospital Corps worked with such energy and rapidity that the amount of work done in the time can only be accounted for by sympathy for the sufferers, and the earnest desire to attend to each one immediately on arrival, enabling them to work uninterruptedly for hours, and to battle against the prostrating effect of the sun. Cases in which bullets were immediately under the skin and could be removed by a small incision were attended to at once, an anæsthetic not being required, and it was marvellous to observe how the despondent and anxious look of the sufferer who begged for the bullet to be taken out was instantly changed for an expression of delight when the unwelcome visitor was put into his hand to be taken home and proudly shown as a trophy among his friends. Opium was administered to those in pain, filtered water in abundance to the thirsty, and nourishment in the form of beef-tea and milk was ready prepared in pails. As soon as dressed the wounded were carefully and gently carried a few yards and placed in cutters and flat-bottomed boats, strewn with hay, which when filled were towed along the canal to Kassassin, returning when empty for another batch. I accompanied one convoy which started in the evening and arrived late the same night. I was delighted with the easy and pleasant motion, and the absence of the jolting of vans or trains, so great a boon in the case of gunshot fractures. On arrival at Kassassin their destination was the canal-lock hospital. Those requiring it were dressed again next day, and while assisting in doing this I took note of the administration of champagne, and of the plentiful supply of ice. From Kassassin in the afternoon I accompanied a train full of wounded, assisting the surgeon who had been sent in charge. Good water, lime-juice, brandy, and Liebig's extract were supplied for the wounded during the journey, and whenever a stoppage occurred every carriage was looked into and

medical comforts supplied to those in need of them. On our arrival at Ismailia station the same evening a surgeon met the train with pails of tea, from which basins and mugs were filled and handed round. So that with regard to the treatment of the wounded during their transport by rail or canal on every occasion on which I had the opportunity of witnessing it, nothing more could have been done. A short distance by the new rail then brought us to the doors of the base hospital. The antiseptic treatment which had been carried out on the battlefield was continued at the base hospital, and carefully followed out until all the wounded were transferred to ships for England; the results obtained so far reflected the greatest credit on the surgeons who employed this method. When ready to be transferred, the sick and wounded had only to be carried a few paces to the nearest point of the canal, in consequence of the dam, constructed at Tel-el-Kebir by the Egyptians, having been cut through after the fight, so that the level of the canal at Ismailia rapidly rose; the canal lock was utilised, and flat-bottomed boats, drawn by a steam pinnace, conveyed the wounded to the vessels in the lake. Practically, therefore, there was water transit from the battlefield to England. The incidents to which I referred were such as follows:—The wounded at the base were dressed antiseptically, and the surgeons in making their daily rounds examined the dressing, and passed over those cases in which, as is characteristic of this method, it was not necessary or even advisable to change it for two or three days. This was in several cases the cause of grumbling and discontent. The soldiers' idea was that if they were not dressed every day they were not being treated properly, so that it became necessary to explain to them that the fact of their not requiring to be touched was a proof that everything was going on well. It is easy to see how a misunderstanding and misrepresentation of this might lead to the report that the wounded were so neglected that even at the base hospital they were left for several days without being dressed! Again, one night a batch of wounded arrived. Nourishment, as usual, was supplied to all previous to their being told off to their respective wards. Next morning, on interrogating a patient as to how he was, he said he was starving, as he had had nothing for nearly two days. I immediately asked him how it was that he missed his turn the night before, and whether he had not had some tea, beef-tea, or milk on arrival. He replied that he did not call that anything, what he wanted was something solid. Anyone believing the man's first statement, without further question, might have been easily misled into the belief that he had actually been starved. From Ismailia, when the hospital had been cleared of all its surgical cases, I proceeded to Cairo, where I frequently visited the Citadel hospital, and found everything equally satisfactory. From thence I went to Alexandria, and re-embarked in the *Lydian Monarch*. Like other civilians, I had formed an erroneous opinion as to the value and efficiency of military hospitals. I have now learnt from my experience in this campaign that not only in essential points are they as well ordered and managed as the best civil hospitals, but that many lessons of great value might be learnt from them by the lay and medical authorities of even the best managed hospitals of our large cities.

## Public Health and Poor Law.

### LOCAL GOVERNMENT DEPARTMENT.

#### REPORTS OF INSPECTORS TO THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

*Enteric fever at Clapham.*—A prevalence of enteric fever in Clapham, and which was locally attributed to the use of milk from a certain dairy, was recently brought under the notice of the Local Government Board, and they instructed their inspector, Dr. Parsons, to inquire into it. Twenty-one persons in sixteen households appear to have been affected, the attacks having occurred in June and July last. Nearly all the houses affected were of a superior class, and they were either situated on the edge of Clapham Common or were widely scattered in the neighbourhood; no two being in the same, or even in adjoining streets. The water-supply was mainly from the Southwark and Vauxhall Water Company; some

three households had a supply from the Lambeth Company; and one used a well on the premises. Investigation exhibited no one sanitary condition as a cause in common to the households affected. When, however, the question of milk distribution came under inquiry suspicion at once attached to the supply of one milk-dealer who obtained a part of his milk from two dairy-farms at Musbury near Axminster. His customers, who were 118 in number, may be divided as follows: eighteen, including a public institution, took "nursery" milk alone; eight used both nursery and ordinary milk; and ninety-three the ordinary milk alone. The enteric fever was found to be entirely limited to the consumers of the ordinary milk, one in seven of every house so supplied being affected. On the supposition that the fever was conveyed by the milk this proportion seems a small one, but it is possible that, in many of the households which escaped, milk was used only in small quantities, and it is further believed that a large consumption implied the use of the article as a beverage uncooked, whereas a small consumption referred to its use in tea, puddings, &c. Several of the houses taking large supplies were affected with the disease. The ordinary milk was supplied from the two farms referred to, and these were in consequence at once inspected. Neither of them exhibited the sanitary conditions which should exist on a dairy-farm. At one the water was derived from a well sunk in a gravelly soil, and was shown on analysis by Dr. Dupré to be largely polluted by sewage or surface drainage, being entirely unfit for drinking or culinary purposes. About eight yards from the dairy and twelve yards from the supposed position of the well belonging to it is a brook which higher up flows through a rough stone sewer. Now, last winter six cases of enteric fever occurred in Musbury, the last one being still ill during the month of March; and it is known that the infectious excreta from this case were thrown into a privy with a vault of primitive construction, from which, when full, the contents are got rid of by pouring down water, and washing them away through a rough drain into the sewer. Having regard to all these circumstances, we gather that the persons affected with enteric fever were not specially exposed to any known local conditions likely to have brought about the disease, that they were not in any close personal relation with each other, but that they had a milk-supply in common, and that this supply came from the dairy-farm in question at Musbury. At the latter village we have further the existence at no remote date of enteric fever, with the possibility of access of the specific poison to the dairy-farm well by percolation from the sewage-polluted brook through a porous gravelly soil; and we feel bound to accept the view expressed by Dr. Parsons, that the water from this well being used for dairy purposes, it is highly probable, if indeed not practically certain, that the infection was distributed by the medium of milk.

*Diphtheria at Folkestone.*—A large fatality from diphtheria in the Folkestone urban district has been under investigation by Dr. Parsons, on behalf of the Local Government Board. The disease commenced in October, 1881, and continued without interruption until the end of May, when as many as 60 fatal cases had been registered, in addition to certain deaths from so-called croup and pharyngitis. This indicates a very serious outbreak, and, unless it was of a specially fatal character, there must probably have been over 300 attacks in all. Of 152 new cases occurring in seventy-five households, and which came under inquiry, the frequency with which the first case in each household proved fatal is noteworthy. Thus, of twenty-seven households in which both fatal and non-fatal cases occurred, in nineteen the first case proved fatal, and in only eight the first case recovered. No satisfactory history could, at the date of the inquiry, be elicited as to the origin of the epidemic. The first person attacked was a child, who did not appear to have been in contact with other persons affected, either in Kent where the disease was somewhat prevalent, or in connexion with the French traffic from Paris, in which city many cases prevailed. As to its spread, it is clear that in many cases the disease was carried from household to household by unrestricted personal communication, and this apart from the ordinary method of infection as the result of school attendance. There was no community of milk-supply, and a large number of houses attacked received their water from the public service which, though intermittent, did not come under suspicion. As regards other matters, however, it is most unfortunate to find that an inspector, in dealing with a health resort, finds himself obliged to report that as regards

local wells "no pains are taken to exclude surface soakage, hence they are very liable to become contaminated." And again, as regards the houses, it appears that "in almost all ..... in which diphtheria has occurred, dangerous communications with the drains were found, of a nature to allow the entry of sewer air into the house." Folkestone has begun to get rid of its shallow surface wells, and, according to Dr. Parsons, it is locally admitted that the number of sewer ventilators is insufficient. Further action should not be delayed, for a good water-service is available, and the circumstances of the sewers are exceptional, owing to the fact that the sewer outlet is tide-locked during the greater part of the twenty-four hours. Amongst the recommendations which are forwarded (together with Dr. Parsons' report) to the Folkestone Town Council is one urging improvement in the ventilation of the public sewers, and the severance of the direct connexion existing between drains and houses. Folkestone possesses an excellent hospital for infectious diseases, but for some reason or another it was allowed, as regards this serious epidemic of diphtheria, to lie all but idle, for "only a single case of that disease" was admitted. The lesson taught in that one instance is, however, noteworthy, for it is reported that in the household from which the patient came no further cases occurred.

### VITAL STATISTICS.

#### HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns, 5468 births and 3308 deaths were registered during the week ending the 21st inst. The annual death-rate in these towns, which had been equal to 19.9 and 21.7 per 1000 in the two preceding weeks, declined again last week to 20.4. The lowest death-rates in these towns last week were 13.7 in Bolton, 14.1 in Norwich, 15.1 in Nottingham, and 16.6 in Bristol. The rates in the other towns ranged upwards to 25.9 in Birkenhead, 28.3 in Cardiff, 31.0 in Preston, and 34.2 in Sunderland. The deaths referred to the principal zymotic diseases in the twenty-eight towns were 535, and within 7 of the number in the previous week; 136 resulted from scarlet fever, 118 from diarrhoea, 92 from "fever" (principally enteric), 91 from measles, 57 from whooping-cough, 35 from diphtheria, and only 6 from small-pox. No death from any of these diseases was recorded in Bolton, whereas they caused the highest death-rates in Preston and Sunderland. Scarlet fever showed the largest proportional fatality in Sunderland and Sheffield; measles in Wolverhampton and Sunderland; and "fever" in Leeds, Blackburn, Liverpool, Portsmouth, and Preston. The mortality from whooping-cough was generally below the average. The 35 deaths from diphtheria in the twenty-eight towns included no fewer than 28 in London, whereas but 7 were recorded in the twenty-seven provincial towns, of which 2 occurred in Birmingham. Small-pox caused 3 deaths in London, 2 in Newcastle-upon-Tyne, and one in Manchester. The number of small-pox patients in the metropolitan asylum hospitals, which had been 79 and 84 on the two preceding Saturdays, declined to 78 at the end of last week; only 8 new cases of small-pox were admitted to these hospitals during the week, against 14 and 13 in the two previous weeks. The Highgate small-pox hospital contained 8 patients on Saturday last, no new case having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 253 and 302 in the two preceding weeks, were 290 last week, and 36 below the corrected weekly average. The causes of 76, or 2.3 per cent., of the deaths in the twenty-eight towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Leicester, Brighton, and in four other smaller towns. The proportions of uncertified deaths were largest in Salford, Hull, Preston, Huddersfield, and Cardiff.

#### HEALTH OF SCOTCH TOWNS.

The annual death-rate in the eight Scotch towns, which in the two preceding weeks had been equal to 22.3 and 19.2 per 1000, was 19.7 in the week ending 21st inst.; this rate was 0.7 below the mean rate during last week in the twenty-eight large English towns. The deaths referred to the principal zymotic diseases in these Scotch towns, which had been 117, 107, and 99, in the three pre-

vicious weeks, further declined to 96 last week; they included 28 from diarrhoea, 23 from scarlet fever, 18 from whooping-cough, 16 from diphtheria, 8 from "fever," 3 from measles, and not one from small-pox. The deaths from these principal zymotic diseases averaged 4.1 per 1000 in the eight towns, and exceeded by 0.7 the rate from the same diseases in the large English towns. The 28 deaths attributed to diarrhoea exceeded the number in the previous week by 2, and were 3 above the number in the corresponding week of last year. The 23 fatal cases of scarlet fever, exceeded the number returned in any recent week, and included 8 in Glasgow, 8 in Edinburgh, and 8 in Paisley. The 18 deaths from whooping-cough were within 1 of the number in the previous week; 13 were recorded in Glasgow, 3 in Greenock, and 2 in Dundee. The 16 deaths referred to diphtheria included 8 in Glasgow and 4 in Edinburgh. Eight of the 5 deaths from "fever" were returned in Glasgow. The deaths referred to acute diseases of the lungs in the eight towns, which had been 102 and 100 in the two preceding weeks, rose to 108 last week, and exceeded by 5 the number in the corresponding week of last year.

#### HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 19.9 and 24.4 per 1000 in the two preceding weeks, declined again to 22.5 in the week ending the 21st inst. During the first three weeks of the current quarter the death-rate in the city averaged 22.3, against 19.8 in London and 17.3 in Edinburgh. The 150 deaths in Dublin last week showed a decline of 13 from the number in the previous week, and included 4 which were referred to diarrhoea, 2 to scarlet fever, and 2 to whooping-cough. Thus the deaths from these principal zymotic diseases, which had declined steadily from 28 to 12 in the five preceding weeks, further fell last week to 8; they were equal to an annual rate of but 1.2 per 1000, the rate from the same diseases last week being equal to 3.4 in London and 3.6 in Edinburgh. The 4 fatal cases of diarrhoea showed a further decline from the numbers returned in the seven preceding weeks. The 2 deaths from whooping-cough corresponded with the number in the previous week, while those of scarlet fever exceeded recent weekly numbers. Only once previously, since the beginning of the year, has a weekly return for Dublin shown no fatal case of "fever." The deaths of infants showed a decline, whereas those of elderly persons exceeded the numbers returned in recent weeks.

#### THE POPULATION OF QUEENSLAND.

An official synopsis of the census enumerations of the population of Queensland during the twenty-one years, 1861-81, has recently been issued, and contains some interesting statistics of the rapid growth of that colony. Six census enumerations were held during the above-mentioned period, and the population increased from 30,059 in 1861 to 213,525 in 1881. Thus the population at the last census was seven times that enumerated twenty years before. As might be expected, the rate of increase is declining, for whereas the population doubled itself in the three years between the enumerations in 1861 and 1864, the increase did not exceed 23 per cent. in the five years between the two last enumerations in 1876 and 1881. A marked feature of the population of all new colonies is the excess of males over females, and the Queensland figures show similar results; it is, however, satisfactory to find that the inequality between the numbers of the sexes is decreasing. At the five enumerations in 1861-76 the number of females to 100 males ranged between 64 and 67. During the five years 1876-81, however, the increase of 40,242 in the population was almost equally divided between the two sexes, consisting as it did of 20,316 males, and 19,926 females. In 1881, therefore, the proportion of females to 100 males had increased to 70. The age distribution of the Queensland population is fully as abnormal as that of the sex proportion. It is not surprising to find that the population contains a largely excessive proportion of young adults and of children, whereas the proportion of elderly persons is exceptionally small. The mean age of the population must also be exceptionally low, and those who still believe in the value of the mean age at death as a test of sanitary condition, would certainly find the mean age at death in Queensland very low, and would be inclined to infer that this fact afforded unfavourable evidence of the health of the population. We need scarcely point out how fallacious

such an inference would be. It appears from the synopsis before us that at the last three enumerations a sickness return has been made. The heading of the columns containing the result of this inquiry is "Sickness and Accidents." The figures tell us that 647 persons were at the time of the last census suffering from sickness in private houses, and 360 in hospitals. It is difficult, without precise knowledge of the instructions given to the enumerators as to the definition of sickness and accident, to estimate the value of these sickness returns. Roughly, however, they appear to show that less than five per 1000 of the Queensland population were at the last census suffering from illness or accident. If these figures are not deceptive, they speak well for the sanitary condition of Queensland.

#### THE SERVICES.

ARMY MEDICAL DEPARTMENT.—Deputy Surgeon-General John Edward Moffatt has been granted retired pay, with the honorary rank of Surgeon-General. Brigade-Surgeon J. Ferguson, to be Deputy Surgeon-General, vice J. E. Moffatt, granted retired pay. Surgeon-Majors Decimus Filius de Hodgson, M.D.; David Mackie, M.D.; Charles Mackinnon; and Campbell Millis Douglas, M.D., V.C., have been granted retired pay, with the honorary rank of Brigade-Surgeon.

Surgeon-Major John Henry Beath, M.D., to be Brigade-Surgeon, vice J. Ferguson, promoted.

Surgeon-Major Henry Hummerston Burford, from half-pay, to be Surgeon-Major, vice A. G. Bartley, retired on temporary half-pay.

Brigade-Surgeon Bruce, officiating Deputy Surgeon-General, Presidency Division, Bombay, is confirmed in that grade and appointment, vice Moore, whose tenure of office has expired.

Surgeon-Major Cameron MacDowall, 3rd Bombay Light Cavalry, is promoted Brigade-Surgeon, vice Bruce, promoted.

BENGAL MEDICAL ESTABLISHMENT.—Brigade-Surgeon Alfred James Dale, to be Deputy Surgeon-General.

MADRAS MEDICAL ESTABLISHMENT.—Surgeon-Majors Henry Cocker, M.D.; Hunter Adam; and Donald Coleman McAllum, to be Brigade Surgeons.

RIFLE VOLUNTEERS.—3rd Monmouthshire: Thomas Gilbert Prosser, Gent., to be Acting Surgeon.

ADMIRALTY.—Deputy Inspector-General John Traill Urquhart Bremner, M.D., has been promoted to the rank of Inspector-General of Hospitals and Fleets, with seniority of October 21st, 1882. Fleet-Surgeons George Robertson, M.D., and George Bewsher Beale, M.D., have been placed on the Retired List of their rank.

The following appointments have been made:—Fleet Surgeon Walter F. C. Bartlett, to Pembroke-yard, vice Wilson; Fleet Surgeon James N. J. O'Malley, to the *Agincourt*, vice Bartlett.

#### "THE TREATMENT OF PAUPER LUNATICS."

To the Editor of THE LANCET.

SIR,—The letter of Sir Henry Gordon, in your last week's issue, touches a point of the greatest importance to the insane poor and to the ratepayers of the county of Middlesex.

My experience, as one of the medical superintendents of Hanwell Asylum for ten years, warrants me in the expression of the opinion I have formed, that the great want for the satisfactory treatment of the insane poor in this county is a hospital constructed and organised on the most liberal principles. Such a hospital, acting as a central receiving house, would greatly tend to check the enormous accumulation of the insane, as well by increase of cures as by preventing the sending of unfit cases to the various distant asylums, and would thus be a source of great economy. Additional economy would also result by saving the large outlay necessitated by transferring patients from one institution to another in the present hap-hazard system of distributing them. Numerous other reasons might be advanced

why a more liberal provision for medical treatment should be made, but I will content myself with one illustration.

In Scotland there are, roughly speaking, 6000 insane paupers in asylums; in Middlesex there are 5700 in the three asylums of Colney Hatch, Hanwell, and Banstead; the latter have fourteen medical attendants; the former, treated in six parochial and eighteen district asylums, have, on the most moderate computation, twenty-four. The comparison might be carried into every detail of asylum accommodation, and in regard to the relative amounts of land provided for asylum use, the inequality would be found still more striking; the one point of medical attendants is sufficient to enforce my argument. What is true of Middlesex is true to a greater or less extent of the whole of England, that, while the buildings for the detention of the insane have been provided on a liberal scale, the means for treatment, as gauged by the numbers of medical officers, have been niggardly supplied; so that in this respect England compares most unfavourably with France, Germany, America, Russia, in fact with almost every civilised country. This result has been brought about by the building funds being derived from a practically uncontrolled source; the current expenditure, on the other hand, being sharply checked by the parish authorities.

I fervently hope that, in supplying the additional accommodation now required, Middlesex will, by providing a liberally organised hospital, set an example that will tend more than anything else to check the increase in this country of lunatics needing asylum detention.

I am, Sir, your obedient servant,

Hanwell, October, 1882.

H. RAYNER.

### STRYCHNIA POISONING DELAYED EIGHT HOURS BY OPIUM.

*To the Editor of THE LANCET.*

SIR,—I think the following case may prove of interest to some of your readers from the long interval between the taking of the strychnia and the onset of the symptoms.

On June 24th last, at 1.50 P.M., I was called to a case of poisoning at the police station, and found in the guard-room a stout, healthy-looking, well-developed young woman of twenty-three, six months advanced in pregnancy, suffering from well-marked symptoms of opium poisoning. She was unable to stand without assistance; could with difficulty be made to answer questions; and her face was becoming pale and ghastly. A quarter of an hour previously she had been discovered in a semi-conscious state near the river, and in her pockets were found a two-ounce bottle containing a few drops of tincture of opium, a packet of Battle's vermin killer torn in two, and with five grains of the powder remaining, and a pill-box which afterwards proved to contain ordinary aperient pills; also a letter to her mother and father stating she intended to commit suicide. I could only elicit from her that she had poisoned herself, but I could obtain no further particulars. I gave a large dose of sulphate of zinc, which produced vomiting in a few minutes, the vomit being composed principally of fruit, and only smelling slightly of opium. After that she had draughts of hot water, coffee, and mustard and water, till her stomach was completely washed out. I left her much better at 2.45 P.M., with directions that she was to be kept walking up and down, and that I should be sent for immediately if any change occurred. I returned at five o'clock, and found her still improving, without the slightest symptoms of strychnia poisoning; so that I began to think it almost impossible she could have taken the vermin killer. In fact, the only difference the case presented from an ordinary one of opium poisoning was that the pupils were little, if at all, contracted; at any rate, not nearly so in proportion to the severity of the other symptoms. I returned about 7 P.M., and found that slight clonic convulsive movements of the hands, and in a less degree of the legs, had set in, and was informed they had commenced a little after 6 P.M. As she was very drowsy, and dropping off between the spasms, and as I thought it possible they might be in great part hysterical, I hesitated about giving chloral; but finding after an hour the convulsions increasing, both in extent and degree, I gave forty grains of hydrate of chloral, and had her removed to the union infirmary. An hour afterwards (9 P.M.) I saw the patient in company with Dr. Paterson. The spasms were now well

marked, extending over her arms, hands, and shoulders, and in a less degree over her legs and feet. There was slight opisthotonos and considerable pain at the pit of the stomach, but no trismus, and but little twitching of the muscles of the face. The pulse and temperature were only slightly above normal. The opium symptoms had almost entirely disappeared. She was ordered two drachms of chloral, half a drachm to be taken every hour. For a couple of hours the symptoms increased in violence, but after that they gradually subsided, and by 4 A.M. (Tuesday) had almost disappeared. Next morning she only complained of general soreness and of feeling very hungry.

On instituting inquiries we discovered that early on Monday morning she had purchased at one shop a packet of vermin killer, and at another an ounce of laudanum, a box of pills, and a drachm of white precipitate. The latter, I may here remark, was never traced. She said herself she had taken the powder a little after 10 A.M., and immediately after two ounces of laudanum. A packet of Battle's contains two grains of strychnia, so that she must have taken almost a grain and a half, and as I did not see her till nearly four hours after, the emetics could hardly have removed it. Though the poisonous dose of strychnia, as in the case of most other drugs, varies greatly from half a grain, which quantity killed Dr. Wain in fourteen minutes, still, I think the above might under ordinary circumstances be considered a fatal dose, particularly when a person is unused to the drug. Taylor mentions four hours as the longest interval before the appearance of the symptoms, while here we have nearly a grain and half producing not the slightest effect for eight hours, during which time the patient had every symptom of opium poisoning with the exception of contracted pupils. Strychnia is said, in poisonous doses, to produce dilatation of the pupils, so that it would seem as if the strychnia must have neutralised the effect of the opium on the pupils; the opium, on the other hand, neutralising, at least for a time, the effect of the strychnia on the cord. I think this might have a practical bearing in strychnia poisoning when chloral or the other usual antidotes, Calabar bean, &c., were not at hand, for though opium is mentioned in books as an antidote, still I think it is seldom or never used.—I am, Sir, yours, &c.,

ROBERT D. W. MECREDY, M.B., C.M.

Gantham, Lincolnshire, Sept. 1882.

### SUDDEN DEATH AFTER DIPHTHERIA.

*To the Editor of THE LANCET.*

SIR,—The following details and observations may help to explain the subject of "Sudden Death following Diphtheria," to which attention has lately been drawn in your journal.

Hitherto it has been considered by many that the action of the diphtheritic virus upon the nerve-centres was sufficient to account for sudden lethal terminations (when not obviously due to other causes), but recent observations may tend to modify that assumption.

During the Practical Pathology class at the Middlesex Hospital, in Nov. 1881, attention was particularly drawn to certain changes present in the heart of a case of diphtheria. The muscular tissue was somewhat pale and flabby, and presented microscopically the following conditions:—Muscle fibres cloudy and undergoing fatty changes; neighbourhood of bloodvessels, interstitial connective tissue and spaces, were infiltrated by an abundant proliferation of nucleated and granular cells about  $\frac{1}{300}$  in. in diameter. Scattered here and there were also seen a few granular, yellow bodies, in size about three times that of nucleated cells, but possessing no distinct nuclei. This condition was not peculiar to any particular portion of the heart's wall, but occurred in several large unequally distributed areas. Both fatty and interstitial changes were seen together.

The following case is also in point:—

Sarah B—, aged fifteen, a domestic servant, was admitted into the Middlesex Hospital, under Dr. Coupland's care, on March 14th, 1882, with marked symptoms of diphtheria—pain on swallowing, dyspnoea, swollen parotid, submaxillary, and cervical glands, and abundant false membrane on tonsils and pharynx; tongue coated thickly; heart and lungs normal. Temperature 98.4°; pulse 64. She was ordered steam inhalations, and a draught containing perchloride of iron. The pharynx was painted with a saturated solution of bicarbonate

of soda. Diet, milk and beef-tea. The urine contained one-quarter albumen. The false membranes soon disappeared, the symptoms rapidly abated, and she seemed very much better. On March 21st she appeared greatly depressed, extremities were cold, and pulse became extremely weak. The urine contained one-quarter albumen. She was ordered a draught of ether and ammonia and brandy. Took her food fairly well. On 23rd, at 2 P.M., owing to the ward being emptied for the annual cleaning, she was removed to another ward, and at 10.45 P.M., same day, died suddenly. At the post-mortem examination both sides of the heart were found filled with coloured fleshy clots; walls pale and soft; valves healthy. The lungs were partly collapsed. The liver was of a nutmeg colour; the spleen soft, not enlarged; whilst the kidneys were swollen and bloodstained. Microscopically the heart presented similar characteristics to those previously described.

With the exception of some observations made by continental authorities—e.g., Leyden and others (*vide* THE LANCET, May 6th, 1882), comparatively slight attention has been paid in Great Britain to this condition of interstitial myocarditis (diphtheritic). Bouchut has stated that endocarditis is a common event in diphtheria; it, however, has not been present in any of the fatal cases which have occurred at the Middlesex Hospital of late years. In conclusion, allow me to note two important details of treatment, which I trust will not be considered irrelevant—viz., the application of solutions of alkalis to false membranes, and avoidance of chlorate of potash. Alkalies acting as solvents of greater portions of inflammatory exudations, are preferable to acids and astringents, since the latter produce coagulation, and therefore cause accumulation of the membrane. Chlorate of potash is contra-indicated by reason of its irritative influence upon the kidneys, and should therefore not be administered internally.

Yours faithfully,

V. A. WYATT WINGRAVE.

Torrington-square, W., Oct. 3rd, 1882.

## "A SIMPLE OPERATION FOR VARICOCELE."

To the Editor of THE LANCET.

SIR,—The diagram of Mr. Dunnett Spanton, in your last impression, represents a "granny's knot," and not a "reef knot," which is on all hands acknowledged to be the superior one for subcutaneous ligature of veins. Both free ends of the wire or cord should be under or above the surface of the loop, conversely, to form the reef knot. In several cases on which I have operated for varicocele, I have done so by placing a doubled strong silver wire, one before and the other behind the veins, with the loop conversely, and passing the free ends inversely through each loop. A reef knot is thus formed which does not give way, and which can be tightened as frequently as deemed necessary by tension of the free ends, which are conveniently held *in situ* by being rolled round small corks. In performing this operation Professor G. H. B. Macleod used to include the veins by making the necessary puncture by means of a trocar and cannula, and passing the wires through the latter. I understand that now he ligatures the veins, and completely excises the intervening portion. In your impression of the 7th inst. Mr. Jalland states that he cuts the ligatures short, drops them into the wound, and closes it over. A piece of Chinese silk is used, previously "boiled for half an hour in a 10 per cent. solution, and afterwards left to soak for some hours in a 20 per cent. solution of carbolic acid." I presume this procedure is intended to kill the Chinese spores in the "Chinese silk." Not so many years ago, a man who confessed to the performance of such a fetish would run the risk of having his personal liberty somewhat circumscribed.

I am, Sir, your obedient servant,

Glasgow, Oct. 21st, 1882.

D. CAMPBELL BLACK.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE, NEWCASTLE-ON-TYNE.—Sixty-one new students have entered at this College for the present year—viz., thirty-one for the full curriculum, and thirty for part of it. The latter, with one or two exceptions, are candidates for the medical degrees of the Durham University, and have entered in accordance with the regulations requiring them to fulfil a year of residence there.

## EDINBURGH.

(From our own Correspondent.)

OPENING OF THE WINTER SESSION.—PROFESSOR CHIENE'S INTRODUCTION TO THE CHAIR OF SURGERY.—THE PHYSIOLOGICAL DEPARTMENT.—THE OLD AND THE NEW LECTURE-ROOMS.—CHANGES IN THE EXTRA-ACADEMICAL SCHOOL.—DR. MILLER'S INTRODUCTORY LECTURE.

THE winter session commenced on Tuesday the 24th. As yet it is impossible to give any accurate idea of the number of students, but so far as can be judged the large entries of recent years will, at least, be maintained. The dissecting rooms of the University, Minto House, and College of Surgeons, are well filled, and the active work of the session has already commenced.

Prof. Chiene, the newly appointed Professor of Surgery, delivered his inaugural address on Tuesday at two o'clock. The lecture was delivered, as is customary on these occasions, in the large chemical lecture-room of the old buildings. The Principal, the President of the Royal College of Surgeons, the professors of the University, a large proportion of the extra-academical lecturers, and many practitioners of medicine were present—indeed, I have never seen the room so completely filled as it was on this occasion. Professor Chiene, who is extremely popular, was well received, and the lecture<sup>1</sup> is acknowledged on all hands to have been a great success. Dr. Chiene thoroughly impressed his audience with his own earnestness of purpose, and with his determination to do all in his power to help each individual student in his work.

Professor Rutherford formally opened the Physiological Department of the new university on Wednesday, the 25th, and delivered an introductory address. The Principal of the University, the President of the Royal College of Surgeons, several of the professors, and a considerable number of practitioners were present, and the large lecture-room, which is calculated to seat 500 students, was completely filled. He reviewed the work done by his predecessors in the chair of physiology, and gave every credit to Hughes Bennett for the foresight and energy he had displayed in organising the first physiological laboratory in Edinburgh, and in having been the first in this country to organise the teaching of practical histology and other branches of practical physiology. He then described the objects to be fulfilled by the numerous departments of the new physiological laboratories, and eloquently pleaded for the endowment of research. He suggested the foundation of Fellowships for young graduates who have given proof of earnestness, of exceptional ability, and of a desire to prosecute original inquiry. By the establishment of such Fellowships, skilled and earnest workers could support themselves and at the same time devote their time and energy to the prosecution of original research, the objects of which are unselfish, and which confer unmistakable blessings on the whole of the human race. He hoped such endowments would fall, not only to the physiological laboratories of Edinburgh, but to all other laboratories in other universities and similar institutions. He announced that the first step towards the realisation of this wide scheme had already been taken, for a liberal gentleman, who desires to withhold his name, had, as a preliminary experiment, generously given five hundred a year to the University of Edinburgh for three years. By this means five working Fellowships of a hundred a year for three years had been established. The appointments to these Fellowships have just been made, and the university authorities are sanguine that the results will fulfil the expectations. He then showed how all the elaborate machinery provided for them in the new buildings was to enable the student to become a reasoning practitioner of medicine, and explained the order of study necessary for that object, illustrating the point by a quaint extract from the introduction to the first lectures on Clinical Medicine given in the Edinburgh Royal Infirmary by Professor John Rutherford a century and a half ago, in which it was pointed out how the reasoning physician differs from the empiric, and what are the studies needed to emancipate medicine from empiricism. The importance of physiological study to the psychologist and metaphysician

<sup>1</sup> The first part of this appears in our present issue.—ED. L.

was then explained, the point being illustrated by a brief account of the mechanism of the organs of sensation. He showed why the physiologist maintains that consciousness and sensation must be regarded as psychical expressions of the activities of nerve cells, although he was unable to offer any explanation of the manner in which they result from physical activities. Lastly, he showed how our knowledge of the telephone is calculated to alter existing theories regarding the sense of hearing, and, through the knowledge thus attained, of the other senses. The lecture occupied fully an hour and a quarter in delivery, and the fact that it was attentively listened to, long after the orthodox hour had expired, is the best proof that can be given of its exceptionally interesting nature and of the lecturer's power.

The increased comfort and advantage of the new over the old lecture-room was very apparent to anyone who attended the introductory lectures of Professors Chiene and Rutherford. The atmosphere in the old chemical lecture-room, which seems hermetically sealed up, with the express purpose of retaining as much foul gas as possible, was simply suffocating, and more than one student actually fainted; while the ventilation in the new physiological lecture-room was extremely satisfactory.
